NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The opening meeting of the session was held on September 25th, 1874, the chair being taken by the President, Mr. C. Hester, who expressed his great pleasure at presiding over such a largely attended meeting.

Mr. G. C. Druce, Secretary, read the following report of the Council for the past session:—

Report.

"The Council, in presenting the fourth report of the Northampton Pharmaceutical Association, has great pleasure in still being able to draw attention to its flourishing condition. Classes in Botany, Materia Medica, Practical and Theoretical Chemistry, and Pharmacy have been conducted during the winter session, but the attendance in the early part of the year, owing to the numerous removals, did not reach the high average of former years.

"Since last session, four members have passed the Preliminary, three the Minor, and one the Major examination, the latter being first in honours.

"During the year several special meetings have been held, at which the following papers were read:—On 'Iron,' by Mr. H. J. Masters; 'The Chemistry of Sugar and Starch,' Mr. O. Wallis; 'Indigenous Botany,' Mr. G. C. Druce; 'Source of Vegetable Matter,' Mr. H. Kemp; 'Pyroxylin,' Mr. W. J. Campling; 'Yeast, Caoutchouc, and Specific Gravity,' Mr. W. Stott.

"The botanical ramble through Brickhill Woods to Woburn Abbey was an extremely pleasant break in the routine of class work; the number of specimens obtained, the picturesque character of the scenery, and the collection of works of art in the Abbey combined to render the excursion in every way successful.

"The Council thanks Mr. Jeyes for the use of the room, the Pharmaceutical Society for the Journal and Calendar, the class conductors for their services, and other friends who have so frequently rendered aid.

"The balance-sheet will show a good sum in hand, and that the expenses of the Association have been again defrayed by the members' subscriptions.

"At the commencement of the Association a loan of £10 was granted by the parent society for the purchase of books and apparatus; that loan this year has to be returned if the condition of the Association is not satisfactory. Hence a further incentive, if any were needed, for strong individual exertion to be made in order to increase and extend its scope of usefulness.

"The new regulations for the Minor examination throw greater responsibility upon the class conductors, which, however, may be much lightened by punctual attendance and strict attention during class time.

"The Council wishes to purchase apparatus for volumetric testing, so as to be able to furnish instruction in volumetric analysis in a class which might also include elementary physics. The library also requires considerably enlarging.

"It is no little satisfaction to the Council to be able to say that ALL the assistants and apprentices in Northampton have joined the Association."

The report was adopted with much applause.

Mr. C. Hester then read the following—

Presidential Address.

Gentlemen,—Called by your suffrages to occupy the presidential chair for the ensuing session, I thank you for the compliment, and for the confidence thus placed in me. I undertake the office more from a sense of duty, and a desire to further the interests of our Association, rather than from any fitness or capability I feel in myself for the position you have assigned me. It will be my desire to render you my best services at all times; and with your co-operation endeavour to promote our mutual advance in pharmaceutical knowledge. You must bear in mind, it is not so much from the chair as from your own individual laborious application to study, at all fitting times and opportunities, coupled with the matured information obtained at no small amount of toil and assiduity, which I am sure our class preceptors will bring to bear upon the subjects in their several departments before they come before you, that we must look and expect to see the fruits of the session in a goodly array of members being duly qualified to pass, with credit to themselves and our Association, the pharmaceutical examinations. As in former years, the Society may be congratulated that we have upon the Council, and as class preceptors, the names of gentlemen who by former services which they have rendered to the Association have proved that they have both the power and the ability to make the Association a great success. I find since the foundation of the Society 67 members have been enrolled amongst us, 1 (with honours) has passed the Major, 10 (2 in honours) have passed the Minor, and 10 the Preliminary. I am very pleased to see present in our midst this evening our late and esteemed President, Mr. Masters, who, if he were still residing in our town, I should prefer to see occupying the position I do just now. I take it that his presence here to-night augurs that he still feels a lively interest in the welfare of our Association, although removed to a distance from us. It would be very unbecoming of me in his presence, as well as distasteful to him, were I to pass an eulogium upon him for his past services, and the ability with which he conducted the business connected with the Society; suffice it to say, that he was one of the first founders of the Society, and for two-thirds of its existence has occupied the position of President, with business tact, courtesy, and magnanimity to all. No word of comment is required from me respecting our indefatigable Secretary, Mr. Druce; his arduous and unremitting exertions for the benefit of the Association are equally known to all of us. I am glad, however, that we have secured his valuable services for another year. My business engagements, I fear, will preclude me from being with you as frequent as I should wish to be; then the duties will devolve upon the Vice-President, Mr. Osborne, who will discharge the duty equally as well, if not much better than myself. For the gentlemen who have so kindly undertaken to prepare subjects for the classes, at such pains and sacrifices of time and pleasure, which their paucity of leisure must of necessity put upon them—I refer to Messrs. Wallis, Druce, Osborne, and Princeps—I ask that you will show your appreciation of their services by being punctual in your attendance at their respective classes, and not letting any small matter prevent your being here as often as possible. If anybody wishes to distinguish himself in any walk of life he must be prepared to make many sacrifices, but don't let the thought of it deter you from aspiring to something great, good, and noble.

> "In the bivouac of life
> Be not like dumb, driven cattle;
> Be a hero in the strife."

Mr. Hester then asked the Secretary to read the financial statement.

Before doing so, Mr. Druce thanked the members for again so unanimously electing him Secretary, and said they would perhaps excuse him for a moment dwelling upon the course of the Association. Begun as it was, with much fear as to its success, the number of possible members being so small and that number disunited, it was felt to be a very risky venture. Many prophecies were made as to the fate of such an attempt, mostly of a gloomy character; some predicted it would end in smoke or smoking, others that its time would be occupied in gossip or in politico-religious controversy. Fortunately, those predictions had been completely falsified, and at the end of three years they could look with complaisant satisfaction at its course. Taken up as it was eagerly by the assistants and apprentices, with aid given as soon as asked from the principals, with a grant from the Pharmaceutical Society, rendered doubly welcome by the kind remarks accompanying it, and with words of advice, warning, and encouragement made personally by Dr. Attfield, an impetus was given to the Association the motive force of which had not yet been expended. The classes had been well attended, the special meetings had been frequent, and the general knowledge of the members would not discredit any association. As the President had noticed, they could show results from their study in a large proportion of qualified members. The continual migration of members of course sapped their strength, but though no longer with them, they did not pass into complete oblivion here, nor was the Association unremembered by them, for some frequently, by correspondence, by sending a prescription of undecipherable caligraphy, by forwarding some strange plant, or compiling a paper, evinced a remembrance as kindly as welcome. With regard to the coming session, Mr. Druce continued, there was little doubt that that could also be made successful. They started with an unprecedented number of members, with energetic class takers, with a good President, with, as they had seen, an ex-President taking great interest in their proceedings, and always ready to come over and help them, and with a strong desire on the part of the members—rendered stronger by the new regulations—to pass not only the Minor examination, but also to obtain a practical knowledge of all the branches of their curriculum. Might the Council ask the members for their assistance during the session in making good classes, and to render all the help they could to their Association? If they did they would make still greater progress, and earn deservedly still kinder praise.

Audited and found correct,

Owen Wallis, J. D. Willis, } Auditors.

Mr. H. J. Masters said it was a pleasure to him to be present that evening, and he much regretted the circumstance of not being still able to be a real member of their Association. He noticed with pleasure the new regulations for conducting the Minor Examination, as he was quite sure they were needed, and would prove conducive to the professional interest of their trade. They made it absolutely a necessity for the members to study their work and perform it practically, and for that practical knowledge the Association's classes would prove of the greatest assistance. Of course it would entail some expense to purchase the apparatus, but he believed the principals in the town would be very willing to become honorary members, and, if so, the money obtained would be of very great service. He was pleased with the financial state of the Association, and considered the fact of their being for two years self-supporting very creditable indeed. Having alluded to the pleasures of the ramble, and expressed a hope that the next might be near Bedford, Mr. Masters concluded a capital address by wishing them every success.

Mr. Shepherd trusted that the members would not overlook the advantages of the Latin tongue.

The vote of thanks to the President was then passed.

Mr. Hester, in responding, thanked the members for their attention, and for appearing in such numbers despite political excitement, this being the largest meeting he ever had noticed in their room. He also was much obliged to Mr. Wallis for taking the Prescription Class, and trusted that and all the other classes would be numerously attended.

Parliamentary and Law Proceedings.

Supposed Improper Use of a Medicine.

An adjourned inquest was held at Dundonald, on Thursday, September 17, to inquire into the circumstances attending the death of Mr. William M'Kee (of the firm of Bryce & M'Kee, seedsmen, Belfast), at his residence, Ballymiscaw, on the 9th September.

The Coroner briefly recapitulated the evidence that had been given on the 11th ult., from which he said it appeared from the testimony of the widow of the deceased that on Sunday, the 6th of last month, he complained of being unwell. He shivered and vomited. On Monday he did not go into Belfast at his usual hour, but dined at one, and went to town at two o'clock. He returned about five, and informed her (witness) that he had been to Dr. O'Hare's medical establishment in Belfast, where he had got a dose of medicine that did him good. He brought a bottle home with him, which he stated he had got at the same place, and which he was to take at three doses—one as soon as he came home, another at bedtime, and a third at six on the following morning. He took the two first doses at the time specified, but felt so well the next morning that he did not take the third, but proceeded to Belfast at eight o'clock in the morning. He returned at two, and said that he had been at the same medical establishment, and got another dose that did him good. He was then sickly-looking, and complained of being ill. He brought a second bottle with him on that day, which he stated he had got at the same place, and was also to take three doses. He got his dinner, and ate heartily. He afterwards took a dose of the medicine, and went out to look after the cattle. In about five minutes he returned and went to bed, and did not complain of being unwell. At five o'clock he asked for tea, but was unable to take it when ready, and again vomited. He afterwards asked for some stirabout, and when given to him he only took a little. At nine o'clock he took another dose out of the bottle, and said it soothed him, and that he felt sleepy. She (witness) then went to bed, and both of them fell asleep. About ten o'clock she was awoke by the deceased coughing, when he said that he had a tickling sensation in his throat, and that his throat was sore. She put some flannel on it, and then returned to bed, when they both fell asleep again. Shortly after eleven o'clock she was awoke by deceased breathing heavily, and then sent for Dr. M'Meekin, of Mountpottinger, the family physician. Dr. M'Meekin was next examined, and deposed that he arrived at deceased's residence about twelve o'clock, and found him breathing slowly and heavily. His face was livid, his pupils enlarged, and he was altogether in a comatose state. He at once suspected poison, and sent to Belfast for Dr. Smyth, of Clarence Place, with instructions to come at once and bring the stomach-pump with him. In the meantime he used every remedy he could possibly think of, but without avail. Dr. Smyth arrived at three o'clock, and they pumped the contents of the stomach, and preserved the same. They remained with him for five hours, but could not succeed in awakening him. He died at five o'clock the same evening. There was no label on either of the bottles, nor any direction as to how the contents were to be taken. Dr. Murney was the next witness. He said he made a *post-mortem* examination. The body was that of a healthy person in the prime of life. There were no marks of violence on it. On examining the brain he found it perfectly healthy, and discovered nothing to account for death. He also examined the chest and abdomen, and found all the organs healthy, and no cause for death. He removed the stomach, and sealed it up in a jar, and handed it to Dr. M'Meekin. A narcotic poison would not leave any trace of irritation behind. Under these circumstances, he (the Coroner) had adjourned the inquiry till that day, in order that Dr. Hodges might submit the result of his analysis of the stomach and the contents of the bottle to the jury; also, that Dr. O'Hare might be present, and that other evidence might be taken.

Sub-Inspector Robertson said Dr. Hodges had not arrived, and no communication had been received from him.

Constable Alexander Fisher was examined by the Coroner, and deposed that he was stationed at Sydenham. On Saturday, the 12th ult., he received from Dr. M'Meekin two sealed bottles and a sealed jar. These bottles and the jar he delivered to Dr. Hodges, in Belfast, on Saturday, the 19th ult.

Dr. O'Hare said he would be much obliged to the Coroner if he would take his evidence now before he called another witness. There was a member of his family lying ill, and he wished to get home as soon as possible.

The Coroner did not think there could be any objection to taking Dr. O'Hare's evidence now.

Dr. O'Hare was then sworn, and examined: My name is Owen Patrick O'Hare.

The Coroner: It is right for me, Dr. O'Hare, before you give your evidence, to tell you that it has been stated that the last medicine the deceased received was prescribed by you.

Dr. O'Hare: I am aware of that.

The Coroner: My duty is to tell you that you are not bound to say anything that may criminate yourself, and anything you may say will be taken down in evidence, and may be used against you hereafter.

Dr. O'Hare: I am aware of my position, and have come here to tell the truth.

Dr. O'Hare (to the Coroner): I am a duly qualified medical practitioner, and a Bachelor of Arts in Trinity College, Dublin. I am a licentiate apothecary, and a licentiate of midwifery. My establishment is at No. 86, Castle Street, Belfast.

Did you know the deceased William M'Kee?—I did, for the last fifteen years. I have been his medical adviser for that length of time.

Have you attended him lately?—My last attendance dates from the 5th June last. I attended him from that time until his death, with the exception of an interval of some weeks. The witness here wished to give in evidence his attendance on the deceased in years prior to the present, but

The Coroner said all they had to do with was the deceased's last illness, and Dr. O'Hare might confine himself to that.

Dr. O'Hare said that in order to explain matters to the jury he would have to go back some years.

The Coroner said that if such an explanation became necessary it could be given at the end of the evidence as to the last illness.

Dr. O'Hare (to the Coroner): The last complaint I attended him for was inflammation of the urinary organs, and acute inflammation of the kidneys, consequent thereon.

You prescribed medicine for him?—I did. The last medicine I gave him was on Friday, the 4th September, about nine o'clock in the morning. On that occasion I gave him two bottles, one to be externally used, and the other internally. They were marked "double strength," in my own handwriting.

Was there anything else on the label?—Yes, "To be taken as before."

Was your name and address on the label?—No. Being the graduate of a certain university that is not necessary on my part. The labels on the bottles were the same as I put on those for other members of his own family.

Did you give him any directions when you gave him the bottles?—Yes.

What directions?—I must give a word of explanation. On that Friday morning before giving the medicine I had an interview with Mr. M'Kee. I explained to him how the bottles were to be taken, and I remarked at the same time that he would require no more. I told him how the one was to be taken and the other used, and that the dose that I prescribed was to be taken three times a day—the dose consisting of a teaspoonful mixed with water. I remarked at the same time that it was double strength, and taken as I directed would prevent a recurrence of the symptoms. On Monday, the 7th Sept., the deceased called on me again. I may add that he called upon me a second time on the 4th ult., about five o'clock in the evening, but that was in reference to the payment of my account. On the 7th, when he came into my establishment, I explained to him the necessity of keeping in his own house. He said he was well, and that he required no more medicine. The dose I last gave him would have sufficed for at least eight days, and I told him he must remain in his house for at least a week.

What was in the two last bottles you supplied to the deceased?—In the first, for external use—Goulard's solution, 4 drachms; water, 7 ozs.; and they were to be mixed and used as directed. In the second, for internal use—infusion of quassia, 2 drachms; infusion of gentian, 1 drachm; liquor potassæ, 3 drachms; solution of morphia, ½ drachm; water, 6½ ozs. After giving him these bottles, I also told him to take a dose of purgative medicine when going to bed that night.

Did you not think it necessary, when giving these medicines containing poisons, to label them according to the Act of Parliament?—That is only required in the case of a druggist.

The Coroner read the sections of the Act of Parliament as to the retail of poisons, and said the law applied to medical men as well as to other vendors, and the penalty for not marking "poison" on a vessel containing poison was £5 for the first offence, and £10 for any subsequent offence.

Dr. O'Hare explained that these bottles did not contain sufficient to cause a person's death.

The Coroner: Morphia is a poison.

Dr. O'Hare: But the half drachm in the bottle would not cause death. I don't retail poisons out of my establishment. Any I use is in my own prescriptions.

The Coroner: In sending out poison in any quantity the Act of Parliament requires that it shall be labelled.

Dr. O'Hare: I put my usual label upon the bottles, and gave my directions as to their use.

The Coroner: Supposing he had taken one of these bottles that you gave him on Friday at three doses, would that have been according to your directions?—No; but if he had taken the bottle for internal use at one dose, it would not have done him a bit of harm.

If he had taken the bottle for external use at one dose, what would be the result?—If he drank it, the result would be serious.

If he took it at three doses, would it be serious?—I don't believe it would. If taken at once it might produce paralysis or lead poisoning.

On Monday, the 7th, did you see the deceased?—Yes. At a few minutes before nine o'clock he came into my place with a leather bag, with a large bottle in it, which he said a member of his family wanted renewed. When he came in I remonstrated with him for being out of his house. He told me he was so ill on Saturday and Sunday that his wife was going to send for a doctor. He did not give that as a reason why he called on me that morning, but that he had to come to town on business. He came back about half-past twelve o'clock the same day, and agreed to pay his account on a certain day.

What was the sum he was to pay?—£10.

Was that for attendance from June?—No, for a later period. On the 8th he called for the bottle which he had left on the previous day. He told me then that he was quite well, and never felt better. He alleged that I was keeping him from his business by being over-careful of him. He took away the bottle of medicine which I had prepared, according to his instructions, for a member of his family. It was a quart bottle he took away. The two bottles he got from me on the 4th ult. contained eight ounces each.

To the Jury—The two bottles contained simple medicine. There was nothing accompanying them.

A Juror: Are the bottles here?

The Coroner: They are with Dr. Hodges.

Juror: There is a possibility that something may have been put into the bottles since they left Dr. O'Hare's place; and I think he should have an opportunity of seeing them.

Dr. O'Hare: I think that is a very just remark, and I am thankful for the juror making it. It would be only justice to me to see the bottles, and ascertain if the contents are as I made them up. I will stand by my own bottles.

The Coroner said that the bottles had been given over to Dr. Hodges, and unfortunately he was not present. (To Dr. O'Hare)—On Monday and Tuesday what appearance did the deceased present?—He was morally downcast. He said his wife should know the nature of the malady he was suffering under. He showed signs of shivering. Goulard's solution is a preparation of diacetate of lead. Dr. Goulard himself was the originator of it. It is poisonous, as all preparations of lead are. There was not sufficient poison in the preparation to cause death. It might cause paralysis. Liquor potassæ is caustic potash.

To Sub-Inspector Robertson—The reason I recommended him to keep his house was in consequence of the inflammation of the kidneys, but not on account of the medicine I had given him.

When the examination had concluded,

Dr. O'Hare asked was he to get a fee.

The Coroner said he had not examined Dr. O'Hare to give medical evidence as to the cause of death, but as the witness who had prescribed the medicine which the deceased had taken.

Dr. O'Hare said he might have used his prerogative, and not attended; but when he received the invitation to attend, and had done so, he thought he was entitled to his fee. He considered he had given medical evidence, and that he was entitled to his fee.

The Coroner believed he could not allow the fee under such circumstances.

Dr. O'Hare hoped the Coroner would not take it ill if he looked for the recovery of his fee in another place.

The Coroner said he would not.

Dr. O'Hare was about to leave, when one of the jurors said he thought the doctor, for his own sake, ought to remain and hear the remainder of the evidence.

Dr. O'Hare: Let me look after my own interest.

Juror: Suppose the two bottles are brought up?

Dr. O'Hare: Then you know where to get me.

Dr. O'Hare then left the room.

Mrs. Margaret M'Kee, widow of the deceased, who was examined on the day the inquiry was opened, was recalled, and deposed, in answer to the Coroner, that on the 11th ult. her husband brought home two bottles, which he said he got from Dr. O'Hare. She gave him the doses out of the bottles according to his instructions.

How did these bottles, with the remainder of their contents, leave your house?—Dr. M'Meekin took charge of them.

Was there any label or writing on either of these bottles?—I did not observe any.

Did your husband say anything to you as to how the bottles were to be used—that one was for internal use and one for external use?—He did not. Both bottles appeared to contain the same kind of liquid. I gave him about a third of each bottle at a dose.

Were your husband and you always on the best of terms?—Yes, always. I never had any dispute with him or any members of his family. I did not know he was being attended by Dr. O'Hare. I never was in Dr. O'Hare's place along with him, but I have been twice there alone.

Did your husband ever threaten to commit suicide?—Never. I never suspected it at all. I was not aware he was taking medicine previous to Sunday, the 6th Sept.

To Sub-Inspector Robertson: One of the bottles was a bluish colour, and the other white. I gave him the medicine out of a wine-glass. I asked him whether I should put water in it, and he said no.

The Coroner: During the days he was taking the medicine did you observe any change in him?—Yes, he was sickly-looking and excited like. There was a strange expression in his eyes, and towards the evening he was drowsy.

To Sub-Inspector Robertson: I am certain that on Monday, the 7th, he did not leave home until two o'clock in the daytime.

A Juror: Did you see any account from Dr. O'Hare?—Yes; after his decease. I found a letter from Dr. O'Hare in his pocket, in which he said his account was £10.

To Sub-Inspector Robertson: I gave him medicine out of both the bottles. The blue bottle was larger than the other one. That was the one he brought on the Monday.

A Juror: Were there any other bottles except these two found?—Yes; there were two bottles found in his coat pockets after his death. There appeared to be about one dose taken out of each. They were about three-quarters full. I have these bottles now in my own house. I did not tell the police I had found these bottles.

The Coroner: It is unfortunate you did not tell the police when you found these bottles. Give them to Constable Fisher when he calls for them.

To a Juror: There was a label on each of the bottles. I could not read the writing distinctly, but I could read the words "double strength" upon them.

A Juror : These must be the bottles Dr. O'Hare described.

To the Coroner : My husband did not tell me of these two bottles during his lifetime. I am certain he told me the bottles I gave him the medicine out of were received from Dr. O'Hare. I am certain he took no medicine out of the two bottles I found in his pocket on the Tuesday evening before his death, as I was in his bedroom during the entire time. He would not let me leave him. It was on Saturday, the 12th, the day he was interred, I found the two bottles in his pocket. I told Dr. M'Meekin on a day last week that I had found the two bottles.

The Coroner said it was unfortunate this circumstance had not been made known sooner, as these two bottles might turn out to be of very great importance in this inquiry. (To the witness) : Have you any further information to give the jury touching your husband's death, or any other matter to explain ?

Mrs. M'Kee : There was another bottle found to-day by my servant man. Wm. Kane is the man's name. He found the bottle in one of the out-offices. It was similar to the bottles I found in my husband's pocket, and had a similar label. It was about three-quarters full. Beside it was found a delf jug containing a white lotion and a glass syringe. I was not aware my husband was suffering from any illness. He was depressed and in low spirits for some time, and I did not understand him.

Dr. M'Meekin, who had been previously examined, was recalled, and said that on the 9th Sept. Mrs. M'Kee pointed out to him two bottles on the dressing table. He sealed them up, and gave them in charge to Constable Fisher. He numbered the bottles 1 and 2. No. 2 he put on the bottle deceased got last. He also gave the constable the jar that had been sealed by Dr. Murney.

Did the deceased present the appearance of suffering from disease such as described by Dr. O'Hare ?—No. I saw traces of a lotion having been applied externally. On Wednesday week I visited Mrs. M'Kee at her residence. She showed me two bottles and a glass syringe which had been found in the deceased's pockets. On these bottles there was a label on which he could read the words "double strength—to be taken as before," or words to that effect. I did not have anything to do with the bottles. Perhaps I was wrong in not doing so, but I did not. The bottles were both eight-ounce bottles. The two bottles which I sealed and gave to Constable Fisher to be taken to Dr. Hodges were both four-ounce bottles. The prescriptions described by Dr. O'Hare would require eight-ounce bottles to contain them.

The Coroner said that there was other evidence to be received, and Dr. Hodges had to be examined. He would, therefore, adjourn the inquiry.—*Northern Whig.*

On Monday last the inquest was resumed and some additional evidence was taken ; but the Coroner stated that as he had received a letter from Dr. Hodges saying that the analysis being of so tedious a character it would take several days more to complete it, it would be necessary again to adjourn the inquiry.

Mrs. M'Kee, widow of deceased, again gave evidence, in the course of which she said that since the inquest was adjourned on Friday last her father had found another bottle in the stable. It was only about a quarter full of the same kind of liquid as the bottles contained which were found in her husband's pockets after his death. Since her husband's death she had received a letter from Dr. O'Hare. In it he said something to the effect that it would be useless for him to sympathize with her for the loss of her truly beloved husband. He then requested payment of his account, which he said was £23 odd. This included an old balance of £6. On the Tuesday evening before his death her husband said it must be some very strange medicine he was getting, it was so soothing. He made that remark after he got the last dose. He said he felt a strange feeling which he never felt before. She asked him if he felt any pain, and he said no. When he was in bed for some time he said he felt his skin in its natural state, and that he was not sweating as he usually did.

The inquiry was further adjourned until Monday next.

Poisoning by Oxalic Acid.

Mr. W. Emsley, Leeds Deputy Coroner, has held an inquest on the body of Louisa Esberger, 27, a housemaid in the employment of Mr. Bruce, Leeds stipendiary magistrate, who died very suddenly. As the girl's death could not be accounted for at the first sitting except by the presence of a quantity of black fluid in the stomach which was supposed to contain poison, Dr. Scattergood and Mr. Horsfall, surgeon, were appointed to make an analysis of it, and the inquiry was adjourned. At the adjourned inquest, it appeared from the evidence that, in June last, deceased took into the house one pennyworth of salts of lemon to take stains out of an apron. A sister of the deceased said that when her sister told her that she was unwell, she asked her if she had taken breakfast, to which she replied that she had had nothing to eat that morning. Witness did not think that her sister and the cook agreed very well, as deceased had told her that they often quarrelled. She did not for a moment believe that deceased had wilfully made away with herself, and there was nothing known to her which would lead her to think so. She was a very quiet girl. Another of deceased's sisters gave similar evidence. Dr. Scattergood said that he had made an analysis of the contents of the girl's stomach, and found that the stomach was of a brownish black colour, and partly corroded, as through the action of some corrosive irritant. The stomach contained a quantity of blood, which had been altered by the action of some acid. He found it to contain 11½ grains of oxalic acid. Some of the acid had also been imbibed by the stomach. He had received a pot of jam from the Coroner's officer, which he found to be wholesome raspberry jam. A bottle also given him by the officer, and labelled "Leeds Penny Relish," contained turpentine, ammonia, etc. The acid found in the stomach was capable of producing all the symptoms he had mentioned, and there was nothing else which could have caused death. Oxalic acid is a poison which acts very quickly—sometimes immediately. The longest time he had known it required to take effect (and this was the only instance he knew) was six hours. It was in the highest degree unlikely deceased could have taken the poison on the previous night. The smallest quantity of this poison he had known to act was sixty grains, and of course the quantity found in the stomach of the girl was no measure of what might have been taken, as the vomiting produced by it is so great that there is but a small quantity found afterwards. At the request of the jury the inquiry was further adjourned. At the further adjourned inquest it was shown that the deceased had previously exhibited suicidal tendencies, having twice secreted a rope. The jury returned an open verdict.

A Child Accidentally Poisoned by Carbolic Acid.

Mr. W. Emsley, Leeds Deputy Coroner, has held an inquest on the body of Ellen Thompson, seven years of age, daughter of a moulder, who died suddenly. In August last deceased suffered from scarlet fever, but had become convalescent towards the end of the month; and on the 24th ult. one of the district sanitary inspectors, named Jos. Thornber, called at the house, and told the mother that he had brought some carbolic acid, which she was to sprinkle down the sink when there was any smell in the house. He asked for something in which to put the carbolic acid, and the deceased's mother brought out a champagne bottle. He refused to use it, and she then gave him two medicine bottles, one of which he almost filled with carbolic acid, at the same time telling her that she was to be careful and keep it out of the way of the children. The mother, however, did not recollect having received the caution. She placed the bottle on a shelf. It appears the deceased had been in the habit of taking coltsfoot wine, which was kept in a bottle that happened to be exactly similar to that in which was the carbolic acid, and on Friday last the child reminded her mother that she had had no wine that day, and said that she would get the bottle and take some herself. Deceased was unable to reach the shelf, but a companion unfortunately took down the bottle with the carbolic acid and showed it to Mrs. Thompson, asking if it was the right one. She was told that it was, and immediately poured out an egg-cup full of the contents. The child simply tasted the acid and then began to scream, and the mistake was at once seen. The child became insensible and died the same afternoon. The jury returned a verdict of "Accidental death," and severely censured Thornber for putting the carbolic acid into a medicine bottle, especially as he had not removed the label on the bottle, and put on the label provided for the purpose by the authorities.

POISONING BY MORPHIA SUBSTITUTED FOR PEPSINE.

Mr. Taylor, Coroner, has held an inquest at the Crown Hotel, Batley, on the body of Mr. Robert Shackleton, borough accountant, who had died from poison administered in mistake. Deceased was subject to dyspepsia, and was in the habit of obtaining a pepsine mixture two or three times a week, at the shop of Mr. Parrington, chemist, Batley. He called there on Tuesday week, and ordered a draught. It was mixed for him by a young man, an assistant to Mr. Parrington, named Scatcherd, who by mistake took down from the shelf a bottle containing morphia, instead of one on the shelf below on which the pepsine was kept. Of this drug he used ten grains. Mr. Shackleton drank off the mixture, and went to a meeting of one of the Corporation committees, at the Town Hall; but the mistake being soon afterwards discovered, he was brought away. Two doctors were called to his aid, and everything done for him that skill and science could suggest. The unfortunate man became in a comatose state; but though he seemed to rally a little on Wednesday, he gradually sank, and died on Thursday night. The jury found a verdict of "Death from misadventure."—*Leeds Mercury.*

THE SALE OF SULPHATE OF ZINC.

At the Marylebone Police-court, on Thursday, Sept. 21st, Elizabeth Oxley, aged 17, described as a servant, was charged with attempting to commit suicide, by taking a quantity of sulphate of zinc.

A police-constable said, on Tuesday evening, the father of the prisoner told him that his daughter had taken poison. He found the prisoner lying on the bed in an insensible condition, and a paper on the table which had contained a quantity of sulphate of zinc, and which her mother said the prisoner had taken. The poison had been procured from Mr. Wimbush, chemist, 195, High-street, Camden-town. Witness did not see on the paper that it was labelled poison. He sent for a cab, placed the prisoner in it, and took her to the nearest medical man, who used the stomach-pump. It was more than an hour and a half before she revived, and she was then taken to the Albany-street Police-station, and thence to the St. Pancras Workhouse, where she had been till that morning.

The mother of the prisoner said that prisoner gave her brother, aged twelve years, a penny, and told him to go to the chemist to get some white copperas; and if he could not get that, he was to get some red precipitate powder. Witness asked her what she wanted with the copperas, and she said her eyes were bad and she wanted to bathe them. The boy returned, and whilst witness's back was turned, she took a glass from the mantelshelf, filled it with water, mixed the powder in the water and drank it off. She became insensible, and the policeman was called. She also said the packet had a red label on, with the word "poison," but she burnt it.

The prisoner, in answer to the charge, said she was very sorry, and if she was discharged she would not attempt to destroy herself again.

Mr. D'Eyncourt said chemists had no right to supply children with poison, and he should remand the prisoner to the House of Detention for a week. The police must have the chemist who sold the poison in attendance on the remand.

TRADE MARKS PROSECUTION.

Mr. Herbert Clarke, known as Dr. Clarke, of High Street, Shoreditch, was on Saturday, Sept. 19, charged on a summons before Mr. Bushby, at Worship Street, under the 25th and 26th Vic., cap. 88, with having forged or counterfeited a trade mark of Francis Jonathan Clarke, and with procuring and using the said forged trade mark to a bottle, and selling the same, contrary to the statute. The complainant is a Mr. Clarke, carrying on business at Lincoln, and is the patentee of a medicine largely advertised as "Clarke's World-famed Blood Mixture." The defendant advertises a medicine which is called "Dr. Clarke's Blood Renovator." The defendant, it was stated by Mr. Salamon in his opening address, had for a long time past misled the public by the style and title of his medicine, by copying the complainant's form of advertising, the style of his bottle wrappers, his trade mark, stamp, and signature. In consequence of complaints the complainant sent his agent to the defendant's shop, and he asked for a bottle of "Clarke's Blood Mixture," and received "Clarke's Blood Purifier."—Samples of the bottles were handed to the magistrate, and it was pointed out that the signature of the defendant was written in exactly similar style, the letters being formed alike. The defendant was known as Davis, and had denied being Dr. Clarke.—A witness, who said his name was John Morgan Davis, the name over defendant's shop, said that he was a chemist, now of the same address as the defendant, High Street, Shoreditch. The business which the defendant had carried on was his, and he had taken it over again during the past six weeks. He had sold it to the defendant four years ago, but because he was not able to pay the money for which the business was sold he had resumed possession. The defendant, he said, was Mr. Clarke.—The witness was cross-examined by Mr. Salamon as to the genuineness of the transaction, and whether it was a sham sale or not, but he refused to say what the terms of the sale were, how much he got, or how the money was secured.—Mr. Bushby thought it curious, and said that he could not withdraw the case from a jury. It did not seem to be altogether clear.—The defendant was then fully committed for trial.—*Standard.*

Obituary.

Notice has been received of the death of the following:—

On the 20th September, 1874, Mr. William George Searle, Chemist and Druggist, of Chorlton-on-Medlock. Mr. Searle had been an Associate of the Society since 1869.

On the 28th September, 1874, Mr. William Farrar, Chemist and Druggist, of Hartlepool.

Notes and Queries.

[412.] TINCTURE OF PHYSALIS ALKEKANGI. —*W. H. Furneaux* wishes to be supplied with the formula for preparing tincture of Physalis Alkekangi.

[*$_*$* We believe that such a tincture is sometimes prepared with proof spirit, the strength being that of the majority of B. P. tinctures,—1 in 8.—ED. PH. J.]

[413.] DISPENSING QUERY.—I should be very glad if any correspondent could inform me what the chemical action is which takes place to throw down a copious muddy sediment from the following mixture:—WM. ROBINSON.

℞	Ferri Tart.	ʒiij ℈j.
	Theriacæ	℥v.
	Spt. Rectificat . . .	℥xv.
	Aquæ	Oj.

Misce.

Correspondence.

Cohesion Figures of Liquids.

Sir,—I am glad to see from the last number of your well-conducted Journal that the above subject is exciting some attention among the pharmacists of the United States, and that a scientific lady has condescended to examine these figures and to describe her observations thereon. The superior delicacy of hand possessed by a lady is likely to be of use, as I have known gentlemen to fail for want of this necessary qualification.

I cannot understand, however, how Miss Kate Crane obtained good figures by allowing the drop to fall through a space of four inches before it reached the surface of the water. In my earliest instructions for forming these figures four conditions were insisted on:—(1) Chemically clean water (not necessarily distilled) in a chemically clean vessel. (2) A vessel of a determinate diameter, always the same. In fact, I had a number of shallow glasses made for the purpose, which I named "cohesion figure glasses," three inches in diameter. These were made clean by means of sulphuric acid, and filled to overflowing with tap-water. (3) A glass rod of determinate size, or a pipette of determinate aperture, in order to insure the same sized drop of the same liquid on all occasions. (4) The gentle delivery of the drop to the surface of the water without any fall whatever.

For want of this last precaution, Miss Crane, as I gather from her descriptions, has not always succeeded in producing the best results. But I must tender her my thanks for her testimony to the value of my test, whether as applied to pure oils or to mixtures.

Some of your numerous readers will probably remember that in March, 1864, I had the honour of bringing this subject before the Pharmaceutical Society. My lecture, and an account of some experiments arising out of it (suggested, I believe, by Professor Bentley), were printed, with illustrative figures, in the Journal for March and April, 1864. My late esteemed friend Professor William Allan Miller, of King's College, was present, and joined in the discussion. He took great interest in the subject, and saw most of my early experiments while on a visit at my house, in August, 1861, and he presided during the reading of my first paper before the Chemical Section of the British Association, at Manchester, in that year. These figures have their highest scientific interest in the fact that they have mainly contributed to the establishment, on a firm basis, of the beautiful theory of the surface tension of liquids.

There is one point in connection with this subject on which I am sorry to have to differ from Miss Crane, and that is with respect to the so-called *oleographs*, or self-printed impressions of these figures on paper. About the end of 1868, Dr. Moffatt was so good as to send me upwards of thirty impressions, illustrative of his process. I regretted at that time (as I wrote in the *Chemical News*) that I was not able to report favourably of them as types of these figures, their chief defect being want of distinctive character. Unless the process has greatly improved (and as I gather from Miss Crane's paper it has not) I must be allowed to retain the opinion then given. The thirty-six oleographs forwarded to me by Dr. Moffatt were so much alike that they might fairly pass for variations of one oil. They consisted more or less of a large disk, perforated with holes, arising from the fact that the oil was left too long before an impression was taken. There is a moment in the existence of every film when the characteristic figure is presented, by which the liquid can be recognized and its purity tested. If this characteristic figure could be seized and fixed at the right moment the process would be of value, for we should then have not only figures of great variety and beauty, but types for comparison. I have published a large number of figures in which the characteristics are presented. Some liquids, such as the oils of lavender, turpentine, coriander, etc., have each two or more characteristic phases. In the *Philosophical Magazine* for June, 1867, I gave the three characteristic phases of oil of coriander. Now, no oleograph of this oil would satisfy me that did not represent these three figures. The third figure of this group would print as a perforated disk (as in Dr. Moffatt's oleographs); but this of itself would be of no value at all, for it would distinguish nothing unless associated with the other two phases which distinguish oil of coriander from all other liquids. Oils of the same family present figures with broad features in common, but with essentially different details, as in the case of castor and croton oils; but if these figures be left but a short time on the water, or other surface, all character becomes lost.

C. Tomlinson, F.R.S.

Highgate, N., September 28th, 1874.

Tincture of Acetate of Iron.

Sir,—Mr. Welborn, in his paper in your last issue, appears to attribute the want of stability of Tinct. Ferri Acet. to the presence of nitric acid in the Liq. Ferri Persulphatis. In this I think he is mistaken. The want of stability is owing to the deficiency of acetic acid, caused, in the first place, by the presence of carbonate in the acetate, and, secondly, by the gradual formation of ethyl acetate, and the consequent abstraction of acetyl from the iron, both tending to promote the production of free oxide of iron.

The addition of a little acetic acid to the preparation before its volume is completed would be found to preserve it from deterioration, if the B. P. and the P. A. (Public Analyst) be so elastic as to admit of such an addition.

William H. Darling.

126, *Oxford Street, Manchester,*
September 28th, 1874.

J. J. Harvey.—As the aim of the writer of the letter complained of was evidently not to injure the sale of any particular article, but to warn his fellow-tradesmen against thoughtlessly falling into a practice similar to that which on more than one occasion has led to annoyance and loss, we must again decline to print your personal strictures on his conduct. As soon as you can state, on proper authority, that the article you manufacture may be sold unstamped, we shall be glad to publish the information for the benefit of the readers of this journal.

T. S.—Your note, with enclosure, has been handed to the publisher.

R. G. B.—The regulations, framed in pursuance of the Order in Council of the 4th June, 1870, were printed in the *Pharmaceutical Journal* for April 15, 1870, p. 828.

W. C. Kidd.—The reaction is represented in the old notation.

A. P. S. G. B.—Titles cannot be obtained from the Pharmaceutical Society by payment, neither are we aware of any that can be so obtained from Apothecaries Hall.

"*Omnibus.*"—A stamp would be required.

"*A Country Druggist.*"—We do not know upon what authority you act as the mouthpiece of "country druggists as a class;" but we do know that what you presume to say in their name does not represent the opinion of more than very few, if any, beside yourself.

"*A Country Pharmaceutical Chemist.*"—Such sales are not "illegal," but we think that considerable discretion should be exercised in supplying such articles to children.

"*A Minor.*"—In section 15 of the Pharmacy Act, 1868, it is enacted that any person "who shall take, use, or exhibit the name or title Pharmaceutical Chemist, Pharmaceutist, or Pharmacist, not being a Pharmaceutical Chemist, . . . shall, for every such offence, be liable to pay a penalty or sum of £5."

J. M.—*Red Fire:* nitrate of strontia, 9 parts; shellac, 3 parts; chlorate of potash, 1½ parts. *Blue Fire:* ammonio-sulphate of copper, 8 parts; chlorate of potash, 6 parts; shellac, 1 part. See also vol. i., p. 357, of the present series of this Journal.

G. C.—The least separation will be secured by rubbing the turps with the yolk of eggs, adding the camphor dissolved in the spirit, shaking well, and, lastly, adding the vinegar gradually, continuing the agitation. It appears to be an imitation of Sir John Long's liniment.

C. B. A.—What you state does not occur if the proper kind of gum is used.

Communications, Letters, etc., have been received from Mr. Darling, Messrs. Cantrell, Davison, and Leslie, Mr. Wilkinson, Mr. J. F. Brown, Mr. Piper, Mr. Tichborne, Mr. Dobson, H. S. D., "Nil Desperandum," "Lapis."

Errata.—On p. 260, col. 1 line 2, *for* "i thyophagi" *read* ichthyophagi; line 41, *for* "Charles I." *read* Charles II.

LINIMENT OF BELLADONNA.

BY CHARLES UMNEY.

When extract of belladonna, made by the complete exhaustion of the root by cold alcohol, is dissolved in spirit of wine in such proportion that one part fluid shall contain an equivalent of one part by weight of the root, or, in other words, if liniment of belladonna (B.P. 1867) be made from the alcoholic extract of the root, instead of from the root direct, even though the quantities be strictly proportionate, the difference in appearance of the two preparations is so marked as to require some explanation.

Haselden (*Pharmaceutical Journal*, 1866, page 17), writing upon this liniment, stated that he had obtained by pressure, after the prescribed volume of the British Pharmacopœia had been percolated, "a considerable quantity of strong tincture, quite equal to that obtained by displacement."

In order to ascertain the extent of the exhaustion of belladonna root by maceration and slow percolation, the following experiments were made:—

The root was dried, and reduced to a "*moderately fine powder*," passing through a sieve of 40 to 50 meshes to the linear inch, for experience had taught me that a "coarse powder," as stated in the British Pharmacopœia, was not well adapted for producing belladonna liniment, for I well knew the difficulty of approaching exhaustion, even with a powder as fine as it is possible to percolate, when the final strength was to be one by weight in one by volume. (I cannot refrain from again* claiming for the U.S. Pharmacopœia a superiority over our British Pharmacopœia in defining the state of division of its powders, which are designated as *very fine* when passed through a sieve *eighty* meshes or more to the linear inch, through one of *sixty* as *fine*, of *fifty* as *moderately* fine, one of twenty *coarse*, and so on.)

100 grammes of this root, thoroughly moistened with spirit, tightly packed in a displacement apparatus, and allowed to digest for three days, was slowly percolated until 100 cubic centimetres was obtained.

The residue was treated with spirit, and similarly percolated until four other portions, each of 100 c.c., were produced.

The extractive these each contained was determined by evaporation and drying at 100° (C.) until the weight was constant. The results were:—

1st percolate . . .	7·58	grammes of extract.
2nd " . . .	4·31	" "
3rd " . . .	3·08	" "
4th " . . .	2·25	" "
5th " . . .	1·54	" "

The first percolate was charged with green colouring matter, which was less perceptible in the second, and almost absent in the other three.

The total extract obtained from the root was upwards of 18 per cent. (18·75) of which—

1st percolate contained . . .	40·4 per cent.
2nd " " . . .	22·9 "
3rd " " . . .	16·4 "
4th " " . . .	12·0 "
5th " " . . .	8·3 "

It would therefore appear that even under very favourable circumstances the root in the liniment of belladonna is not even half exhausted (40 per cent.), at the stage at which the B.P. directs the percolation to be stopped, and the chances are that, in the majority of cases, operating on coarsely powdered root, little more than one-third (33·3 per cent.) is extracted in the first percolate.

If this latter be true, and doubtless it oftentimes is, it would seem, noting the sum of the first and second percolates (63·3 per cent.), that it would be possible under the most favourable circumstances, operating upon very fine powder, to prepare a liniment, from half the quantity of root, almost as strong in extractive at any rate as the present officinal preparation.

I am not prepared to say that each percolate will contain an amount of atropia strictly proportionate to its extractive, but still I imagine there is some alkaloid value in each and every percolate, or the Pharmacopœia would not direct, under "*Atropia*," the exhaustion of *one pound* of root with *five* pints of spirit of wine.

The different appearance of a solution of extract in spirit, and the liniment prepared according to the official directions, is then chiefly due to the imperfect and uncertain exhaustion of the root, and also in a measure to the concentration of the green colouring previously referred to, in the first percolate.

The suggestions I would make, for consideration on some future occasion, when a revision of the Pharmacopœia may be deemed necessary, are, either to substitute *ten* ounces of root in fine powder for the present twenty ounces, and produce finally by the slowest percolation *twenty* ounces fluid of liniment, or to direct a solution of *one* part of alcoholic extract in *ten* parts of spirit of wine.

Either of these would certainly be likely to give more uniform results, under all circumstances, and also lessen the loss of spirit of wine very considerably in the preparation of the liniment.

Laboratory, 40, *Aldersgate Street, E.C.*

* *Pharmaceutical Journal*, 1873, p. 715.

NOTE ON TINCTURA QUINIÆ AMMONIATA, B.P.

BY J. F. BROWN.

There is no necessity for employing heat in the preparation of this tincture, as directed in the Appendix.

If the quinine be diffused through half the given quantity of proof spirit, and then the solution of ammonia, previously diluted with the remainder of the spirit, added, and the whole well shaken, a clear solution will be immediately obtained.

LIQUOR OPII SEDATIVUS.

BY P. WELLS.

Since the institution of the Pharmaceutical Society, papers have from time to time appeared in the Journal respecting the mode of manufacture and the composition of this valuable preparation, but I have failed to note that any one has expressed any belief in the statement of the inventor, the late Mr. Richard Battley, that it was composed of opium and water. Relying on the accuracy of the statement in question, I turned my attention to the preparation of Liquor opii sed. about thirty-three years ago, and at intervals since that time I have manufactured it, with an uniform result, and I now detail the process: I select 12 ounces of the finest Turkey opium sufficiently dry to be reduced to moderately coarse powder, and this I mix intimately with a proper quantity of clean sand.

Before percolation was so well understood as it is now, I thoroughly exhausted the opium with successive portions of water, but of late years I have used the percolator, and have passed water through until it came out nearly colourless.

The liquors are mixed, and after standing a few hours to deposit are strained off and evaporated over a naked fire in an enamelled pan by rather rapid ebullition to about three imperial quarts.

This is allowed to stand in an open jar or any other vessel for fully twelve hours, and then carefully strained through flannel to separate the resin and flocculent matter, and then boiled down to three pints. After standing for twelve hours in a cool place, it is now filtered through paper, and 14 ounces of rectified spirit, 60 o. p., added and made up to four imperial pints with distilled water.

Sometimes I have used 6 ounces of fine dry sherry instead of the water necessary to make up the quantity to four pints.

In about a week the preparation assumes the taste and smell peculiar to Liquor opii sedativus.

A NOTE ON THE BEHAVIOUR OF CERTAIN FLUORESCENT BODIES IN CASTOR-OIL.*

BY CHARLES HORNER.

Some colouring matters derived from woods, not showing any fluorescence when dissolved in water, alkaline solutions, alum, or alcohol, are found to exhibit this phenomenon on treatment with castor-oil; whilst other substances, which fluoresce in alcohol, etc., are observed to show this property with augmented intensity.

To obtain clear solutions, the materials are first boiled in alcohol, filtered, evaporated to dryness, and then heated with the oil. On transferring some of the prepared solution to a test-tube and re-heating, the fluorescence disappears as the temperature approaches the boiling point, but returns on cooling. Moreover, this operation may be repeated without the substances suffering decomposition. Cudbear, camwood, logwood, and turmeric are selected as illustrations of the properties cited.

Cudbear yields a brilliant orange fluorescent light, and is visible in diffused daylight without the agency of a condensing lens, which is necessary to show it in an alcoholic solution.

Camwood exhibits a powerful apple-green fluorescence, although wholly destitute of this property in aqueous or alcoholic media. The spectrum of the fluorescent light is continuous from E downwards, interrupted by two narrow, faint shadings, situated at $3\frac{3}{4}$ and $\ddot{5}$ of Sorby's scale.

With regard to logwood, unless the castor-oil solution be saturated, sunlight and a lens are requisite to bring out its fluorescent character. The colour very much resembles that of camwood, but is distinguished by its spectrum, which is continuous from *b*, but interrupted by two shadings at $\ddot{4}\frac{1}{4}$ and $5\frac{3}{4}$.

Turmeric is well known to fluoresce powerfully in alcohol a yellow green, and in benzole a blue green. In castor-oil, however, the fluorescent light is at least three times as bright as in other fluids, and may be described as a vivid emerald green, evident in the dullest daylight; but if a flat bottle of the solution be placed on black velvet behind rather deep cobalt glass, when the sun is shining, the phenomenon is of a most brilliant description, and without exaggeration may be compared to that produced by the beautiful uranium-glass. The spectrum furnished by the fluorescent light is characterized by transmission of red and green rays, and blue to F, with a faintly perceptible shading at the yellow end of the green.

These facts therefore show that, in studying the phenomena of fluorescence, advantage should be taken, whenever possible, of this valuable solvent property of castor-oil.

* From the *Philosophical Magazine* for September.

REPORT ON THE GOVERNMENT CINCHONA PLANTATIONS IN JAVA.

FOR THE SECOND QUARTER OF THE YEAR 1874.

Although the abundant rains that have fallen were not unfavourable to cinchona culture, they have checked the field work, and rendered difficult the collection and drying of the bark, so that the harvest commenced in May was carried on slowly and with difficulty. Nevertheless, 9,000 kilograms of bark are already collected, and everywhere preparation is made to carry on the collection energetically as soon as the dry weather sets in. Through free labour the gathering becomes more and more difficult; in fact, the wages will probably become a very important item.

The fructifications of *C. Calisaya Ledgeriana* have as yet yielded only a few seeds, and have been disappointing, some of the finest specimens having flowered unproductively. Extraordinary care and attention were therefore devoted to the artificial production of this superior kind, and better results were obtained. Within eight months nearly 13,000 *C. C. Ledgeriana* plants were obtained from slips, whilst 5,400 have already been planted out.

Through the thinning out of the original plantation of 1866-7, 750 trees of *C. C. Ledgeriana* were sacrificed, and thereby 1,500 kilograms of fine bark were obtained, which also was very rich in quinine. The larger gross product which is obtained when more light and air are afforded to the plants has been again very clearly demonstrated by this collection. At Riung-gunung the trees are planted at a distance of from 6 to 7 feet from each other; at Tji-bürrüm, at a distance of from 4 to 5 feet. The average production of each tree in the former establishment was four kilograms, including the root bark, against one kilogram at Tji-bürrüm.

The chemist on the cinchona plantations continues his experiments upon the various kinds of cinchona grown under different conditions and of different ages. His results show that among the smaller varieties of *C. Calisaya* also there is an increased richness in quinine; so that there is a well-grounded expectation that a large portion of this year's collection from *C. Calisaya* plants will yield a product especially suited for the quinine manufacturer.

On the 31st of March last the fourth public sale of Java bark (1873 gathering) took place at Amsterdam. 15,419 kilograms were offered for sale and bought, whilst quite 5,000 kilograms were lost in the steamship Prinz Hendrik, and about 500 kilograms were retained for the Dutch medical department. This product was on the whole favourably reported on by a committee of experts invited to examine it. But the result of the sale has in some measure given rise to disappointment in Java. The manufacturers' bark again fetched an extraordinarily high price, and the bark powder, which last year could only be sold at fl. 0·33 per kilogram, obtained on this occasion fl. 1·11 per kilogram. On the other hand, the price obtained for the greater part of the ordinary Calisaya bark was far below that of former sales.

The more exact descriptive estimates, which were prepared in accordance with the analytical experiments of the chemists connected with the plantations and were circulated for the public sale, were evidently accepted with confidence, and business was facilitated by their use. Acting upon the friendly counsel of one of the most eminent Dutch quinologists, the experiment is to be made of bringing the bark suited solely for pharmaceutical purposes into the market in larger quills and sticks. Probably its value will thereby be enhanced, because in pharmacy its worth is estimated more from external appearance.

In June last the chemist again sought to work up a portion of the small waste bark at Bandong into crude alkaloid. Nearly 1,000 kilograms of the dried product are already under treatment, but the result cannot be stated until the next quarterly report.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 10, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE INAUGURAL ADDRESS.

THE words "fitly spoken" by Mr. GILES, on Wednesday evening, to the students in the Pharmaceutical Society's School of Pharmacy, were listened to with a sustained interest which found its exponent and contrast in the burst of applause that followed his last good wish and admonition. And that interest was heightened when the speaker expressed his gratification that he had been allowed to close a pharmaceutical career commenced as a student in that same school by addressing those students who to-day seek instruction from its professors.

No adventitious circumstances, however, were required to commend the Address to the judgment of the student; the printed page is no less eloquent than was the living voice. Never losing sight of the fact that the occasion was an "Address to Students," and not for a manifesto on pharmaceutical politics generally, Mr. GILES, besides giving much sound advice, succeeded in throwing into a concrete form the thoughts floating in many minds on subjects of vital interest to his hearers. It was judicious to tone down any exaggerated views of the student as to his future calling by linking to the description of pharmacy thirty years ago the reminder that pharmacy is still a trade, although perhaps this is only part of the truth; but it was added that its status "will be best raised by the diffusion of a higher educational tone" amongst those who practise it. It was useful to urge upon him that the time is approaching, probably, when every well-educated Englishman will possess at least an elementary knowledge of the physical sciences, and that if pharmacists are to hold their own, it will be by possessing a relative proficiency in the sciences allied to their art. It was wise to remind him that this was the fleeting, golden opportunity—and probably the only one he would have—for laying a good foundation for that proficiency. And it was kind to tell him roundly that the bugbear "cram" is not an accident of locality; but that it is born whenever the examiner's shadow blocks out the view of what should be the student's goal. Finally, it was well to restore to the well-worn motto its Virgilian form, "Labor omnia vincit."

Mr. GILES sounded no uncertain note of warning as to the future. If the evil which the new examination regulations have been designed to stamp out should prove more than temporary, Mr. GILES sees the "obvious remedy in the establishment of a compulsory curriculum of education at recognized schools as a condition of examination." And it may be added that many others who love the welfare of pharmacy are gradually coming to the same conclusion. Dr. GREENHOW, however, the same evening "ventured to say the days of 'cram' would now be over."

One curious incident of the evening was the almost identical terms in which Professor ATTFIELD and Mr. GILES denounced the moral injury done when a student,—blinded perhaps by over much anxiety to a clear perception of what is honest,—commences what is more or less a methodical attempt to pass for what he is not. This concurrence, however, was only the expression of the opinion of all justly-balanced minds, and it was but a repetition of words spoken by the wise man three thousand years before, "Whoso boasteth himself of a false gift is like clouds and wind without rain."

THE INTERNATIONAL PHARMACEUTICAL CONGRESS.

IN another part of this Journal will be found the Report of Messrs. GREENISH and SUTTON, the delegates appointed to represent the Pharmaceutical Society of Great Britain at the recent Congress in St. Petersburg. It will be noticed that besides the discussion of subjects affecting more particularly Continental pharmacists, some progress was made towards the construction of an International Pharmacopœia, by an agreement as to the principles upon which it should be based. Further the MS. prepared by the Paris Society of Pharmacy was presented, and it has been referred in sections to various members of the Congress to examine and report upon. We have been informed that to Mr. SUTTON has been allotted the portion including the preparations of soda, potash, silver, and gold, and to Mr. GREENISH the preparations of iron. But what will probably affect English pharmacists first, in point of time—although at an interval of four or five years—is, that the Council decided to invite the Congress to hold its next meeting in London. There is every reason to think that the invitation will be accepted, and we believe that such a gathering will have an important and beneficial influence on English pharmacy.

THE YORKSHIRE COLLEGE OF SCIENCE.

WHEN the founders of the Pharmaceutical Society first undertook the task of raising pharmacy from the low position it held in this country thirty-three years ago, they rightly judged that one powerful lever would be found in the diffusion of a knowledge of the scientific principles upon which the practice of pharmacy should be based. There were in those days many persons who looked askance at their proceedings, and would have been well content to follow the "rule of thumb" without disturbance;

unfortunately, too, this class has still its representatives in the present day. The signs of the times, however, show that in seeking to base their art upon science, pharmacists will not be singular, only they have had the good fortune to commence the work rather earlier than some of their neighbours. The earlier attempts to encourage the supplementing of a technical training by a scientific education, which would foster the application of scientific principles in manufactures, did not meet with much encouragement from the classes they were intended to serve. But the apathy of past years is fast disappearing, and the demand for such instruction—especially in chemical science—is now becoming so great that, although increased accommodation has been provided at South Kensington and other schools, it is still barely equal to what is required.

The Yorkshire College of Science is the latest outcome of a widely-spread feeling that if England is to maintain her lead in the arts and manufactures, scientific teaching must be placed within the reach of her workers. According to its prospectus, a copy of which has been sent to us by the Honorary Secretary, Mr. Richard Reynolds, of Leeds, this College is established to supply instruction in those sciences which are applicable to the Manufactures, Engineering, Mining, and Agriculture of the county of York; also in such arts and languages as are cognate to the foregoing purpose. But, although pharmacy is not specially mentioned in the prospectus of classes, some of the courses would, undoubtedly, be valuable to any pharmaceutical students who may be able to avail themselves of them.

The first session will commence on Monday, October 26, 1874, and end on Friday, July 23, 1875; it will be divided into three terms. There will be a class for the study of Experimental Physics, meeting twice a week through the entire session under the charge of Professor A. W. Rücker, M.A., Fellow of Brasenose College, Oxford: Fee, £2 12*s.* 6*d.* Professor Thorpe will deliver a course of lectures, extending through the first and second terms of the session, on Inorganic and Organic Chemistry: Fee, £4 4*s.* Also a course of lectures on Laboratory Practice, Qualitative and Quantitative, on Thursday afternoons, during the first and second terms: Fee, £1 1*s.* There will be further a laboratory course of Practical Chemistry in the College Laboratory, under the supervision of Professor Thorpe: Fee for students working six days a week, £17 17*s.*, and in proportion for shorter periods. The other courses embraced in the programme are Mathematics, Geology and Mining, and Textile Industries. The promoters hope to be able to add to these subjects hereafter. We believe that prospectuses of the classes, etc., may be had on application to Mr. Henry H. Sales, Secretary, Leeds.

Mr. W. Dittmar, F.R.S.E., Demonstrator in the Chemical Laboratory of Owens College, Manchester, has been appointed to the Chair of Scientific Chemistry in Anderson's University, Glasgow, where he succeeds Dr. Thorpe, recently appointed Professor of Chemistry in the Yorkshire College of Science.

Dr. Andrew Fergus, who recently showed his interest in the pharmacy of Glasgow by delivering a lecture before the Chemists and Druggists' Association, has been elected President of the Faculty of Physicians and Surgeons in that city.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, October 7th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Brown, Frazer, Greenish, Hampson, Owen, Radley, Rimmington, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, and Williams.

The minutes of the previous meeting were read and confirmed.

The late Mr. George Edwards.

The President said he could not commence the business of the day without alluding with great regret to the death of Mr. George Edwards, of Dartford, a former member for many years both of the Council and of the Board of Examiners, and a gentleman who had on many occasions rendered valuable services to the Society. Mr. Edwards was a member of the Council from 1847 to 1869, and again in 1871, when he was chosen Vice-President, an office which he had previously filled in 1855. He died on Sept. 13th, aged 66. The President begged leave to move that a letter of condolence be sent to Mrs. Edwards in the name of the Council.

The Vice-President seconded the motion, which was carried unanimously.

The late Mr. Henry Deane.

The Secretary read the following communication, which had been received from the Pharmaceutical Society of Massachusetts, relative to the late Mr. Henry Deane.

"Massachusetts College of Pharmacy,
"Boston, July 28, 1874.

"*To the Pharmaceutical Society of Great Britain.*

"At the regular July meeting of the Board of Trustees of the Massachusetts College of Pharmacy the following resolutions were unanimously passed:—

"'Whereas the members of this College have learned with sincere sorrow that Henry Deane, of London, departed this life April 4, 1874, and

"'Whereas we, in common with the pharmacists of Great Britain, mourn the loss of our friend, who has for so many years maintained so high a rank in his profession as to be regarded one of the ablest and wisest leaders in all matters relating to the progress of pharmacy, and

"'Whereas Henry Deane was an honorary member of this College, and well known to us by his valuable contributions to pharmaceutical science, by his purity of life, by his genial disposition, by his great moral and professional worth; therefore be it

"'Resolved, thatin the death of Henry Deane, pharmacy has lost an honoured, respected, and devoted representative; society an honest, high-minded, and cultivated gentleman; and his family one who in all the relations of husband and father was most tender-hearted and affectionate.

"'Resolved, that to the afflicted family of the deceased, and to our brethren of the British Pharmaceutical Society, we tender our earnest, heartfelt sympathy for their affliction and bereavement.

"'Resolved, that we will cherish the memory of Henry Deane as that of a just and noble man, whose good work in all the varied relations of life is an example well worthy of our emulation.

"'Resolved, that copies of these resolutions be sent to the family of our deceased friend, and to the Pharmaceutical Society of Great Britain, and that they be spread on our records.'

"Very respectfully,
"George F. H. Markoe,
"Corresponding Secretary."

The Secretary was requested to acknowledge the letter, which was directed to be entered on the minutes and published.

Mr. SANDFORD, in connection with this subject, said he was glad to announce that he had now received, within a few pounds, the sum required for the portrait of Mr. Deane, to be placed in the Council-room. He hoped therefore, with the co-operation of two or three other gentlemen, to immediately make arrangements for getting the work executed.

THE CONGRESS AT ST. PETERSBURG.

Mr. GREENISH presented the following report with regard to the recent visit to St. Petersburg of a deputation from the Pharmaceutical Society of Great Britain.

"*To the President and Council of the Pharmaceutical Society of Great Britain.*

"Gentlemen,—The delegates appointed by you to represent the Pharmaceutical Society of Great Britain at the fourth International Congress, to be held in St. Petersburg, from the 12th to the 18th of August, arrived in that city on Monday, the 10th, and, with other delegates, occupied apartments engaged for them at the Hotel Demuth. In the evening of Wednesday the 12th, there was a social gathering of all the delegates, when they were introduced to each other by members of the Organization Committee. The number of delegates was 17, representing 12 societies:—

"Austria, Dr. Von Waldheim, Vienna; Professor Godeffroy, Vienna.

"Bohemia, Herr Dittrich, Prague; Herr Janauscheck, Prague.

"Denmark, Herr Madsen, Copenhagen.

"England, Mr. Greenish, London; Mr. Sutton, Norwich.

"France, M. Méhu, Paris.

"Russia, Professor Dr. Trapp, St. Petersburg; Herr Rennard, Secretary Pharmaceutical Society, St. Petersburg (not a delegate); Herr Jordaen, St. Petersburg; Professor Dragendorff, St. Petersburg; Director Kymenthal, Moscow; Herr Frederking, Riga; Professor Torno, Kief; Herr Theegarten, Odessa.

"Hungary, Herr Pecker, Buda Pesth.

"Poland, Herr Lilpop, Warsaw.

"The room was decorated with flags of all nations, and the delegates distinguished by a white ribbon. On the morning of Thursday, the 13th, the business of the Congress commenced. The chair was taken by his Excellency Privy Councillor Trapp, Director of the Pharmaceutical Society of St. Petersburg, who opened the Congress by a short address. Four delegates were then told off to examine the credentials, which, being done, the election of officers took place, with the following result:—President—Dr. Von Waldheim, of Vienna. Vice-Presidents—Messrs. Madsen, of Copenhagen, and Trapp, of St. Petersburg. Secretaries—Messrs. Rennard, of St. Petersburg; Méhu, of Paris; Sutton, of Norwich; and Janauscheck, of Prague.

"It was unanimously determined by vote that the business language of the Congress should be German. The third question on the programme was taken first, the others being referred to committees for consideration, previous to their discussion in open congress. That question was, 'Is it necessary that the Professorship of Pharmacy should be held only by a pharmacist?' To understand the bearing of this question, it may be necessary to remark that in Germany there are no schools devoted to pharmacy alone, as that of Great Britain. The universities supply professors in every branch of science, the same professorship including materia medica and pharmaceutical chemistry, and the chairs are sometimes given to those who may know little practically of pharmacy and its requirements, the pharmacists themselves having no voice in the selection.

"Your delegates expressed the opinion that the word 'necessary' should be altered to 'desirable.' They did not consider it 'necessary,' but 'desirable,' that the professorship should be held by a practical pharmacist. In the alteration of the word to 'desirable' they were supported by those who subsequently addressed the meeting. Your representatives did not fail to state that for the chairs in the school of pharmacy of Great Britain the Council choose their own professors, and that each of the professors had received the advantage of a pharmaceutical education. They pointed out that, therefore, as regarded this subject, the pharmacists of Great Britain were in a different position to those on the Continent, but at the same time they expressed an opinion on the general bearing of the question. It was unanimously resolved that it is most desirable that the professors of pharmacy be pharmacists, and that materia medica and pharmaceutical chemistry should form separate professorships.

"In the afternoon the committees were occupied with the consideration of some of the other questions, and framing reports upon them for the next day's Congress.

"Friday, the 14th, was occupied with the reading of several scientific papers, and discussions thereon.

"Saturday, the 15th. The question No. 1 in the programme came on for discussion: 'How far does the personal responsibility of assistant pharmacists extend in the exercise of the duties of their calling?' This question involved the responsibility of assistants in case of errors in dispensing. On this subject there seems to exist no definite pharmacy law on the Continent, and it is the general wish that the relative responsibility of assistant and employer should be well defined. There was some discussion as to whether only examined assistants or examined assistants in the position of managers should be held responsible, and it was finally resolved that, for the purity of all drugs, and the quality of pharmaceutical preparations, the proprietor should be responsible; that he should, in no case, be able to shirk his personal responsibility; that if the assistant is aware of a drug used in the pharmacy being adulterated he should be equally responsible with the employer; that the proprietor should be also responsible for the apprentice; that all assistants legally qualified to dispense prescriptions should be personally responsible for any mistakes committed by them, and also that when in the position of manager, in the absence of the principal, they should be responsible for the errors of the apprentice.

"On this question your delegates stated that in Great Britain if an assistant, by an error in dispensing, caused injury to or the death of a person, that assistant was criminally responsible, but that the master was also liable to damages in any subsequent civil action, and that no arrangement among pharmacists could override the general law of the land, as embodied in Lord Campbell's Acts, according to which the master is responsible for the acts of his servants. But your delegates added it was a question which had engaged the consideration of pharmacists in Great Britain, who were desirous of influencing public opinion thus far, that if a legally qualified assistant in dispensing a prescription committed a mistake which resulted in the injury or death of a patient, the fact of the proprietor having employed such an assistant, and taken all other reasonable precautions, should operate favourably in mitigation of damages in any subsequent civil action.

"Question No. 2 on the programme was: 'What is the best mode of organizing the Apothecaries' Committee of Revision?' The Revisions Commission is that body whose duty it is to examine the drugs and preparations in the establishment of the apothecary. In large cities it is usually composed of two pharmacists, one medical man, and one chemist, and in provincial towns the commission consists only of one medical man. It is considered that medical men and also pure chemists cannot be proper judges of drugs and pharmaceutical preparations, and after much discussion it was resolved that in the Committee of Revision appointed by Government there ought to be one practical pharmacist, whose duty it shou'd be to make the examination of any suspected drug; that this pharmacist ought to be elected by the pharmaceutical body and not appointed by Government, several pharmacists being named by that body, from whom the Government should choose one; and that, if there should be a difference of opinion on any subject, the difference should be submitted to a Government Commission, composed of medical men and examined pharmacists in equal proportions.

"Your delegates remarked that practically in Great Britain there existed no such institution as this for examining pharmaceutical preparations and drugs in the shops of pharmacists, and therefore English pharmacists had no direct interest in the question before the Congress. Yet since the delegates believed that the effect of decisions in questions affecting pharmacy could not be altogether localized, but that their influence, directly or indirectly, for good or evil, must be more widely felt, and as they recognized in this discussion an effort on the part of pharmacists to shake themselves free from the control of medical men and pure chemists, so that in all matters relating to pharmacy the pharmacists themselves may be more largely represented, or have the entire control, they had no hesitation in stating that in these efforts the Continental pharmacists had the entire sympathy of the pharmacists of Great Britain.

"Question 4 in the programme: 'Has not the time arrived for instituting an international pharmacopœia?' On this subject your delegates held, that although they did not consider that the time had arrived for instituting an international pharmacopœia, yet it was very desirable that in all active medicinal preparations there should be an effort made to establish uniformity of strength. As regards the issuing of a pharmacopœia, and the preparations contained therein, the pharmacists of Great Britain had at present no power of decision. To illustrate this part of the subject, the first paragraph of the preface to the 'British Pharmacopœia' was read to the Congress, and the composition of the General Medical Council explained. Your delegates added, that the subject had engaged the attention of British pharmacists, and it was hoped that no future pharmacopœia, or additions to the pharmacopœia, would be compiled without the presence of some pharmacists chosen by the Council of the Pharmaceutical Society, or otherwise to assist the Pharmacopœia Committee in their arduous labours.

"After much discussion on the different points in connection with the international pharmacopœia, it was resolved that the best thanks of the Congress should be given to the Pharmaceutical Society of Paris for the suggested international pharmacopœia, of which they sent a manuscript copy. It was decided also that it is desirable that an international pharmacopœia should be compiled; that each country should form its own pharmacopœia; but that the Congress wished that these separate pharmacopœias should be based on the principles of the international pharmacopœia.

"The Congress named a commission to examine the preparations described in the Paris work. The reports from those appointed on the commission are to be sent to St. Petersburg before the 1st December next, and the committee in St. Petersburg will then send the revised work to the pharmaceutical societies of all countries; the cost of transcribing or printing is to be paid in proportion by each society (probably £1 each). It is hoped that the Governments of the several countries interested will institute a commission to approve or otherwise of the international pharmacopœia, so that a small condensed international pharmacopœia shall be the ultimate result. The Congress desired to submit for the consideration of any such commission the following recommendations:—

"1. That the international pharmacopœia should be in Latin.

"2. That the metrical system of weights and measures should be adopted where absolute quantities are required, but that in the preparation of chemicals or galenicals proportional parts only should be used; all temperatures to be given on the centigrade scale, and specific gravities all to be taken at 15° cent.

"3. That the nomenclature should be on one principle. Many of the delegates wished that the committee should be recommended to adopt the nomenclature of Berzelius. There was great division on this point, but the majority were in favour of the proposition.

"4. That the names of drugs adopted in the international pharmacopœia should be as simple as possible, consistent with being definite.

"5. That the minimum of the active principle of narcotic drugs permitted should be definitely stated.

"6. That tinctures and galenical preparations should be made on one principle—for instance, rhubarb 1 part, alcohol 10 parts—and with the greatest simplicity, avoiding unnecessary ingredients.

"7. That in all chemical preparations the maximum of permitted impurity should be stated. Ex., chloroform contains alcohol; it should be definitely stated how much will be permitted. It was not thought necessary that preparations of this kind should be required to be absolutely pure.

"Your delegates took part in the committees for the consideration of the several questions previously to their being openly discussed, and on every question they were heard in full Congress. When the subject was one in which they considered Great Britain had no direct interest, but where the progress of pharmacy or the emancipation of the pharmacist was involved, they expressed in general terms their sympathy with their colleagues in the object they had in view.

"At intervals during the sittings of the Congress the following papers were read on scientific subjects:—'The Electrolysis of Water,' by M. Janauscheck; 'On Some Alkaline Chlorides,' by Professor Godeffroy; 'The Spectroscope Applied to the Detection of Poisons in Cremation,' by Herr Popl, jun., St. Petersburg; 'Tannin and its Salts,' by Professor Dragendorff; 'Conversion of Grains to Grammes,' by Professor Waldheim; 'Aloin from various Aloes not identical, some Amorphous, others Crystalline,' by Professor Dragendorff. There was also shown by Professor Dragendorff an interesting collection of drugs from Turkestan. A description of these will be found in 'Buchner's Repertorium.'

"At the close of the Congress the question as to the next place of meeting was discussed, and an invitation from the United States that it should take place in Philadelphia was communicated. Your delegates stated that they had no authority to invite the Congress to London, and explained that the question was brought before the Council, and postponed to a future meeting for discussion. It was suggested to them to telegraph for instructions on this point, but they considered that the subject could be more satisfactorily discussed on their return. They expressed a wish, however, that London should be named, pending further instructions on the subject, and they added, that should an invitation be sent from the Pharmaceutical Society of Great Britain, and that invitation be accepted, they felt satisfied that this fourth International Congress in St. Petersburg would not exceed in hospitality the fifth International Congress in London. Your delegates cannot close this report without recording their sense of the great hospitality shown to them by the Russian pharmacists. The presence of delegates from Great Britain was especially appreciated, and they know nothing that would give more satisfaction to their colleagues on the Continent than a hearty invitation from the Pharmaceutical Society of Great Britain to hold the fifth International Congress in London. Thus, while cementing old friendships, an opportunity would be afforded of forming new ones, and at the same time advancing the cause of European pharmacy.

"At the close of the Congress the President, in an able and eloquent address, reviewed the work done, thanked the several committees for the assistance afforded him and declared the duties of the Congress closed. A cordial vote of thanks was unanimously passed to the President for the ability and courtesy which he had exhibited, and which had contributed so much to the general good feeling which prevailed, and the satisfactory termination of the Congress.

"In conclusion, your delegates, on their way through Sweden, and also in St. Petersburg and Moscow, availed themselves of the opportunities afforded them of visiting several pharmacies, and making some inquiry into the conditions under which pharmacy is pursued in those countries; these form no part properly of this report, but they hope at a future time to bring some of the points which bear on British pharmacy under the notice of the Pharmaceutical Society.

"Thomas Greenish,
"Francis Sutton."

It was then resolved unanimously—

"That the report of the delegates to the International Pharmaceutical Congress be received, entered on the minutes, and printed in the Society's Journal and Transactions; and that the thanks of the Council are due and are hereby tendered to the delegates for their valuable services and their excellent report."

Mr. Greenish expressed his regret that his colleague, Mr. Sutton, was not present, but he was sure the vote of thanks would be received by him, as it was by himself, with very great pleasure. He might say that they left England with a great sense of responsibility, since they went as representatives of a pharmacy which could scarcely claim an existence of forty years, which was still hardly recognized by the Government, and not yet fully appreciated either by medical men or the public. On the other hand they had to meet men representing a pharmacy which had been in existence for probably two centuries, during which time it had been nursed, protected, and privileged by Government, and assisted by the most systematic education—men who had succeeded in raising pharmacy as an art to pharmacy as a science. These gentlemen, therefore, not only occupied a high social position, but were men of high scientific attainments. He was quite sure, however, that nothing would give these gentlemen greater satisfaction than to meet English pharmacists in this country. He would therefore move—

"That the International Pharmaceutical Congress be invited to hold their next meeting in London."

He was sure, from what he had heard when in St. Petersburg, that it would be a serious disappointment to many Continental pharmacists if such an invitation were not received. He only wished the Council could have heard the shout of satisfaction from the assembled body when the subject was mentioned. He believed it would be one of the best things possible for English pharmacy, and would give it a stimulus which would be very useful by being thus brought into contact with men of such scientific attainments and position.

Mr. Hampson had much pleasure in seconding the motion.

Mr. Williams considered it very important that this motion should be supported, and thought it the duty of the Society to take advantage of such an opportunity as this. He could not but be sensible of the deficiencies of English pharmacy, and the only ground which could arise for hesitation in this matter, was the doubt whether it was really in such a position as to be able worthily to receive such men. However, he understood that the next Congress would not take place for five years, and as the difficulty he alluded to would probably decrease every year, he hoped the Council would adopt the resolution, and that the pharmaceutical body generally would bear in mind the duties they would have to perform.

Mr. Schacht most sincerely hoped this Congress would be held in England on the next occasion, but he wished to know exactly what was meant by giving such an invitation. If it implied extending hospitality to the members of the Congress in the same way as if a private individual invited a friend to visit him, it was doubtful how far a changing body like that Council was justified in issuing it.

Mr. Greenish said he had had some conversation with the President of the Congress on this subject, and his decided opinion was that the only hospitality requisite or desirable was that extended when the meeting was held in Vienna, viz., one dinner to the members.

Mr. Brown did not think there could be any misunderstanding as to the real meaning of the invitation, any more than in the case of the other scientific congresses which now took place every year.

The resolution was then passed unanimously.

Elections.

Several individuals who had neglected to pay their subscriptions in proper time were ordered to be restored to their former status on payment of the subscription for the current year, and a fine.

Finance.

The report of this Committee was read and adopted, and various accounts were ordered to be paid.

Benevolent Fund.

This Committee had held a meeting at which some of the applicants for relief had attended, and now made a report including a recommendation that the following grants be made:—

£15 to the widow of a member, £5 at once and the remainder to be placed in the hands of a member of the Council for application in his discretion.

£30 to the widow of a member who has five children dependent upon her, the eldest aged eight years, the object of the grant being to get one of them into an institution.

£20 to the widow of a registered chemist and druggist at Westminster.

£10 to a chemist and druggist at Sheffield, in distress from continued illness.

£10 to a chemist and druggist in London, in distress from serious illness.

Two other applications were deferred until the Committee had seen the applicants.

Mr. Brown said he noticed that large sums were now being voted by the Committee, and it was evident that, like indiscriminate alms-giving, this would do more harm than good, unless the greatest care were taken that only proper objects were relieved, and that the aid was given in such a way as to permanently benefit the applicants. No doubt many cases of real distress did occur, but some experience as a Poor Law guardian had made him somewhat incredulous in such cases except after full inquiry. He did not oppose the granting of relief, but only wanted care to be taken, and to have some assurance that the machinery adopted for making inquiries into these cases was really competent to discover any attempt at imposition.

Mr. Owen said the case in which the largest grant was proposed had been deferred from the previous meeting in order that the Committee might see the applicant personally, and he believed every gentleman present took the very greatest care not to recommend any grant without being thoroughly satisfied of its necessity. In the particular case referred to, it was considered useless to make a small grant only.

Mr. Greenish remarked that at the previous meeting it had been decided that the Committee should see the applicants, if possible, before making any grants.

Mr. Robbins said this plan had been put in practice for the first time on the previous day, and he believed it would prove very useful. He quite saw the necessity for each case to be carefully looked into.

Mr. Williams said it was rather a serious matter to make a grant equal to a year's annuity; and he had some misgivings whether the practice of seeing the applicants personally would not place those in the country at a disadvantage.

The Vice-President said he could bear testimony to the care and painstaking of the Committee in the distribution of the funds, but he should be very pleased if Mr. Brown would allow his name to be added to the Committee. He might add that the Committee took every pains possible to satisfy themselves that every applicant who came before them had good grounds for the application. He had the fullest confidence in the Committee that no country application would suffer by the arrangement to require a personal interview with those applicants who resided in London, and his experience for some years had shown him that relief had been as freely given to persons in the country as to those in the metropolis.

Mr. Baynes, a country member, wished to state that the country members generally had full confidence in the Committee, and he was satisfied that the general feeling was that they were doing the best they could with the money placed at their disposal.

Mr. Hampson wished in some degree to support what had been said by Mr. Brown with regard to the care which ought to be exercised in making these grants, for he thought they ought to be even more careful in the future than they had been in the past. It was quite possible that other means than those already employed might be adopted to ascertain the genuineness of the cases which came before them, and it had occurred to him that they might utilize some officer of another society, accustomed to the investigation of such cases. He knew such a course had been adopted in Manchester with very good effect. He did not mean for a moment to say that they had distributed the fund without due care, but it was impossible to take too much pains in such matters.

Mr. Brown wished to add that he did not desire at all to call in question the administration of the benevolent fund, and it was quite in accordance with a former suggestion of his own, that grants made to individual cases of distress should be larger in amount than they had been, as more likely to be permanently useful. But as the amounts increased it was necessary that greater care should be exercised, and therefore he thought it might be worth considering whether they might not avail themselves of some other machinery, such as that of the Charity Organization Society, for investigating the cases that came before them.

The report was then unanimously adopted.

House.

The report of this Committee, stating that the principal part of the repairs, etc., which had been in progress in the house had been completed, was received and adopted.

Mr. Greenish called attention to the gas fittings in the museum, and the room above it, which he considered defective, causing not only a waste of gas, but an unnecessary amount of heat in the room. The matter was referred to the House Committee.

Pharmacy in Ireland.

The Secretary, having read a communication received from the Chemists and Druggists' Association of Ireland on the subject of extending the Pharmacy Act to that country, the Council resolved itself into a committee to consider this communication, and ultimately the following resolution was unanimously carried :—

"That it is desirable to extend the provisions of the Pharmacy Act to Ireland, and that the Secretary be instructed to inform the Chemists and Druggists' Association of Ireland that, though this Council cannot undertake to frame any measure for this purpose, should such be submitted to the Pharmaceutical Society or Parliament, every consideration would be given to it; and in the meantime the following gentlemen are appointed to conduct, in conjunction with the Secretary, a friendly correspondence with the Chemists and Druggists' Association of Ireland respecting the provisions desirable to be embodied in legislation : The President, Vice-President, Messrs. Betty, Brown, Greenish, Hampson, and Sandford."

Report of the Board of Examiners.

The Board of Examiners for Scotland reported that during the month of September they had held five meetings, and examined as follows :—

SCOTLAND.

September, 1874.

Examinations.	Candidates. Examined.	Passed.	Failed.
Minor, Sept. 22nd...	17	3	14
" " 23rd...	15	6	9
" " 24th...	17	8	9
" " 25th...	19	8	11
" " 28th...	7	3	4
	75	28	47
Modified " 28th...	4	4	0
	79	32	47

The Secretary also read the report of the deputation appointed to visit the North British Branch, on the occasion of the last examination, expressing generally great satisfaction with the arrangements made in Edinburgh for conducting the examinations, etc., and making suggestions for the improvement of certain matters of detail in connection with the institution there. The report was received, and the thanks of the Council voted to the deputation.

Mr. Hampson asked if Dr. Maclagan, the Government assessor, still continued to ask students questions respecting the use of the microscope?

The Vice-President said that during the three days the deputation was present Dr. Maclagan was unwell and not able to attend; but he believed he might answer the question in the negative.

Mr. Williams said he should like to hear the candid opinion of the deputation as to the value of the new premises in Edinburgh, and whether they were equal to the position and dignity of the Society?

The Vice-President said the premises themselves were all that could be desired; the only exception which could be taken to them arose from the fact of their being situated above a ground-floor used for business purposes. But as that was not considered an objection by the members in Edinburgh it was not for the deputation or the Council to complain, and probably the use of conspicuous door-plates, etc., would meet all the necessities of the case. As far as the rooms were concerned nothing could be better.

A letter having been read from the Honorary Secretary of the North British Branch, stating that money was required for current expenses, a grant of 100*l.* was made accordingly.

The Proposed Monument to Scheele.

The Secretary read a letter which he had received from the Acting Consul-General for Sweden and Norway, drawing attention to an address issued by the pharmacists of Sweden, and published in the Stockholm newspapers, inviting subscriptions for erecting a monument to the chemist Scheele, in his native town; any surplus being devoted to issuing a complete edition of his works.

The President said unfortunately the Society had no money at its disposal for such a purpose.

Mr. Greenish said he would recommend any who were not thoroughly acquainted with the works of Scheele to read a lecture delivered about a year ago by Dr. Tilden on his life and discoveries.

Mr. Williams said the Council officially could not do anything in this matter, but many gentlemen, no doubt, would be glad to contribute in their individual capacity. Probably the best plan would be to insert the communication in the Journal, and state that subscriptions would be received by the Secretary or the President. At the same time the occasion might be taken advantage of to invite subscribers to the memorial to Baron Liebig, which was not supported as it ought to be.

Mr. Brown said he believed the fund for the Liebig memorial was suffering for want of publicity; it had never been advertised in the large manufacturing districts of England, where he believed it would meet with very general support.

The Manchester Chemists and Druggists' Association.

Mr. Brown said he thought the time had come when this Association had a fair claim to a considerable grant from the parent Society. He had often opposed small grants to provincial Associations, for he believed many had made the mistake of applying at the outset instead of waiting until they had accomplished a certain amount of work, and then coming to the Society for recognition of what they had done. The Manchester Society had been established for many years, and since its formation in 1868 it had spent between £600 and £700, besides more than £60 in the formation of a library, and this was a fair guarantee that they had been in earnest in the work they had undertaken. This work resolved itself, primarily, into educational arrangements for the young men of the district, and hitherto these had been conducted entirely at their own expense; but they found that the number of young men who availed themselves of these facilities was not sufficiently large to properly remunerate the very efficient teacher whose services they had been fortunate enough to secure, and it had been necessary during the last session to give him a considerable grant in addition to the fees. This amount he thought they might fairly ask the parent Society to reimburse them. He did not ask them to vote a sum at once, but simply that the matter should be referred to the Pharmaceutical Education Committee, when he would attend before it, and show good reasons why they should recommend the Council to take such a course. If they did not do so he might again bring the subject before the Council itself. The amount he asked for was £50, which would, of course, be required annually,

Mr. Baynes said he cordially agreed in the spirit of Mr. Brown's speech, especially as the Hull Association had only a week ago passed a resolution to much the same effect.

Mr. Williams asked why the application could not be made, in the usual way, to the Pharmaceutical Education Committee.

A considerable discussion ensued on this point, Mr. Brown stating that he did not consider that, under the existing regulations, his application could properly made, in the first instance, to the Committee. Ultimately, however, after consulting the regulations he withdrew his motion, in deference to the generally expressed opinion of the Council, stating that he would make the application in the ordinary way to the Committee.

PHARMACEUTICAL MEETING.

Wednesday Evening, October 7th, 1874.

The Opening Meeting of the Session 1874-5 was held at 17, Bloomsbury Square, on Wednesday evening last. The chair was taken by the President, Mr. Thomas Hyde Hills.

The following list of Donations to the Library and Museum was taken as read, and the thanks of the Society were voted to the donors:—

'Proceedings of the American Pharmaceutical Association, 1873,' from the Association; 'Smithsonian Reports, 1871-2,' from the Smithsonian Institution; 'Third Annual Report of the Alumni Association of the New York College of Pharmacy,' from Mr. P. W. Bedford, Secretary; 'The Edinburgh University Calendar, 1874-5,' from the University; 'The Glasgow University Calendar, 1874-5,' from the University; 'Statistical Tables of Patients, 1873,' from St. Bartholomew's Hospital; 'Zwelfer's Animadversiones in Pharmacopœiam Augustanam, 1675,' from Mr. F. Andrews; 'Introduction to Pharmaceutical and Medical Chemistry,' from Dr. Muter.

Specimens of Sulpho-Carbolate of Sodium, from Mr. Hampson; Iron containing Titanium made from the Iron Sand of South Australia, an Emu's Egg, and Specimens of Quandang Stones, from Mr. Percy Wells; a Specimen of the Silphium Root of Cyrenaica, from Vice-Consul Henderson, of Bengazi; Fine Specimen of Larch Bark, from Mr. F. J. Hanbury; Specimens of Myristic Acid, Myristicate of Barium, and Myristicate of Sodium, from Prof. Flückiger; Specimen of the Wood of the Titi Tree of Honduras, from Mr. F. J. Chard.—For the Herbarium: Specimen of Artemisia Cina, from Prof. Dragendorff; Podophyllum Peltatum, Tulipa Sylvestris, and Holosteum Umbellatum, from Mr. Corder; Rheum Officinale in flower, from Mr. D. Hanbury; Colchicum Autumnale, from Mr. J. A. Jones.

Professor Redwood's Report upon the Chemistry and Pharmacy Class.

The Chairman then called upon Professor Redwood, as the senior professor, to present his report in reference to the Chemistry and Pharmacy Class.

Professor Redwood said the duty he was now called upon, in conjunction with his colleagues, to perform, was always a pleasant one, and not less so on this than on any former occasion. With regard to the class under his especial charge he could report very favourably in every respect. He had never had a more attentive, more industrious, or altogether a better conducted class than that of the last session. He had delivered two courses of lectures, the first terminating at the end of February, as to which he had already reported to the Council that the conduct of the students was everything that could be desired, and that the progress made by them in their studies, as far as he could judge by the weekly and other examinations, was quite satisfactory; so much so, indeed, as to satisfy him that a lecture course of five months' duration—which was about the length of the courses in all the great schools—was better for the students than a long and wearisome course of ten months, such as they had been previously accustomed to. His experience, indeed, was that before the termination of such a course the interest and application of the students too often began to flag. The course which ended in February consisted of sixty lectures, and leaving out those who entered after the course commenced, and one or two who left before it ended there was an average of more than 55 out of the 60 lectures attended by each student—a result superior to any he had ever before experienced. The attendance also at the weekly examinations throughout the course was unusually good, indicating an interest on the part of the students in the subjects treated of; and the proportion of those who entered as competitors at the examinations for prizes was greater than it had ever been on any former occasion in his experience. He had also reported to the Council in equally favourable terms on the second course. With regard to the prize examinations, there had been at the end of February an examination confined to students who had attended the first course, to whom a bronze medal was offered. Fifteen students presented themselves, and of these, six acquitted themselves in a sufficiently creditable manner to have entitled them under ordinary circumstances to some mark of distinction; the Council, however, had only offered one prize, and therefore nothing more could be given, though several students had been induced to compete in the hope that certificates of merit would be awarded. The successful competitor was Mr. James Kemble, who gained 90 per cent. of the possible number of marks. At the conclusion of the second course in July there were two examinations, one open to all students, for which a silver medal and certificates of honour and merit were offered, and the other confined to students of one course, a bronze medal only being offered. In the first examination there were thirteen competitors, seven of whom had obtained some mark of distinction. That these were all good men might be inferred from the fact that while the highest on the list obtained 90 marks out of 100, the lowest obtained as many as 70. The names were as follows:—Mr. William Henry Symons stood first, and obtained the silver medal; next came Mr. William Ayton Gostling, Mr. Harry Alma Thomas, and Mr. Alexander Whyte, all of whom came very nearly up to the first; and these gentlemen obtained certificates of honour. Then came Mr. Arthur Pearson Luff, Mr. Henry George Greenish, and Mr. William Arthur Thirlby, who were entitled to certificates of merit. In the examination for the bronze medal there were fewer competitors than on the previous occasion, arising from the fact that it was now known that no certificates would be awarded, because students soon came to know amongst themselves those who were likeliest to succeed in getting the only prize offered, and those who had not great confidence in themselves declined to compete. The successful candidate was Mr. William Henry Symons, who although only a one course man, had gone in for both examinations, and obtained the bronze as well as the silver medal. He had only to say further that he hoped those gentlemen who had really worked assiduously and well during their studentship, and who, he believed, had richly merited the rewards they had obtained, might be stimulated thereby to add further credit to the institution which was now conferring these marks of distinction upon them, and to advance by their future labours the cause of pharmacy which the institution had so deeply at heart.

The President then distributed, with a few appropriate words in each case, the prizes to the successful candidates, whose names are above mentioned.

The following were the questions for these examinations:—

The Bronze Medal.

Chemistry and Pharmacy.

Hours—Two to Five, p.m.

1. Describe the method of determining the specific gravity of a solid substance, such as wax, which is insoluble in water, and lighter than water.
2. Explain the phenomenon of capillarity.
3. Describe and explain the phenomenon of fluorescence.
4. How much water is required in a refrigerator for condensing the vapour of a gallon of water in the process of distillation? State the temperature of the water when introduced into, and removed from, the refrigerator, and mention the data on which the calculation is based.
5. Describe the sources and mode of production of carbonate of potash in the different states in which it is met with in commerce, or required for use as a chemical reagent.
6. Describe the pharmacopœia process for diluted phosphoric acid; explain what occurs in the process, and why the arrangements indicated are required.
7. What is the composition of acetic acid, and the strength of the different forms of this acid ordered in the pharmacopœia.

The Silver Medal and Certificates.

Hours—Ten to One, and Two to Five.

Morning Paper.

1. What is the value of the gramme weight, expressed in grains? What are the relations existing between the gramme, decagramme, and centigramme?
2. What is the weight of a fluid ounce of nitric acid, B.P.?
3. Name two or three articles that undergo liquid diffusion readily, and others that diffuse slowly or not at all.
4. What are the latent heats of water and of steam, and how are these latent heats determined?
5. What are the specific heats of water, oil, and mercury, and how are they determined?
6. Describe the principle of the action of the siphon.
7. Explain the meaning of the terms, *digestion*, *maceration*, *percolation*, *displacement*, *elutriation*.

Afternoon Paper.

8. Describe the production of oxygen gas, its characters and properties, and means by which it may be identified.
9. How is peroxide of hydrogen obtained, and what are its properties and composition?
10. Describe methods by which the decomposition of water may be effected, representing the products and reactions.
11. By passing chlorine gas into solution of caustic potash, either chlorate or hypochlorite of potassium may be produced. Explain the conditions that determine the formation of these products respectively.
12. What general characters apply to the group of ligneous, saccharine, and amylaceous bodies, and in what cases and under what conditions are some of these converted into others?
13. Describe the production of alcohol, ether, aldehyd, and acetic acid. Explain the relations of these to each other and their compositions.

Professor Bentley's Report on the Botany and Materia Medica Class.

Professor Bentley next gave his report as to the Botany and Materia Medica Class, commencing by saying that, although he had, in common with the rest of the world, taken a short vacation at the end of the summer, he found himself more pleasantly occupied when addressing his class in that institution. Dr. Redwood had so fully entered into the subject of the changes in the arrangements of the School of Pharmacy that he would not occupy time by going over the same ground again, though he most cordially supported everything which his colleague had said with regard to the conduct of the students—their diligence, and the progress they had made during the past year. There had never been a session in which he was more satisfied with the proportional attendance during the lectures, and especially during the examinations; and he could also say that all those awards which the Council had been recommended to make had been honourably obtained. The conduct of the students had been admirable, not only in that institution, but also at the gardens of the Royal Botanic Society, where they might perhaps have more excuse for taking recreation; he was happy to say, however, on this occasion, as he had done for twenty-five years, that whilst there they only thought of the work they came to do, and did not attempt to play until they got outside the gates. In the first course the bronze medal had been honourably obtained, with a high standard, by Mr. William Ayton Gostling; there was a good competition, and he should have liked to recommend to the Council several other competitors for decoration, had there been any distinction in the shape of certificates to award. With regard to the prizes delivered at the conclusion of the session, there was again a bronze medal for the five months' course, which was also honourably obtained by Mr. Alexander Whyte. There, again, there was a smaller competition, because the students knew pretty well the respective merits of their associates, and as there was but one prize open to them, the competition was necessarily limited. The prizes awarded for the whole ten months were only given after a searching written examination, and also a *vivâ voce* examination in systematic and practical botany. The silver medal was obtained by one of the Bell scholars, Mr. Arthur Pearson Luff, who, he was quite sure, judging from the very high merit he had exhibited on the present occasion, would maintain the credit of that name which was so much endeared to all in that Institution. Mr. William Arthur Thirlby and Mr. Alexander Whyte also obtained certificates of honour; the first being but very little behind Mr. Luff, the latter, he believed, having obtained 116 marks out of 125, and Mr. Thirlby 113; Mr. Whyte also obtained a very good proportion of marks. Certificates of merit were also awarded to three students who most honourably distinguished themselves, namely, Mr. W. A. Gostling, Mr. W. H. Symons, and Mr. Henry George Stacey. All these gentlemen might be called up by the President, with the fullest confidence that the progress of pharmacy would not deteriorate in their hands.

The following were the questions given at the conclusion of the first course in the examination for the bronze medal:—

Botany and Materia Medica.

Hours—Ten till One.

1. Define the following:—parenchyma, prosenchyma, chlorophyll, raphides, prickle, spine, tuber, tubercule, rhizome, and bulb.
2. What are the distinctive characters of roots and stems? Give a general sketch of the structure of an acrogenous stem.
3. Describe generally the structure of the seed, and explain the process of germination.
4. What are the geographical and botanical sources of Peruvian and Savanilla rhatany? Give the general characters of the two kinds, and mention the official preparations of rhatany in the British Pharmacopœia.
5. From what plants is Alexandrian senna derived? What are the common adulterants of this kind of senna, and how may they be detected?
6. How is scammony obtained? What are the characters of pure scammony? With what substances is it adulterated, and how may they be detected?
7. Distinguish between "mealy" and "non-mealy" sarsaparillas. What kind of sarsaparilla is official, and what are the preparations of the British Pharmacopœia?

The following were the questions for the examinations at the conclusion of the session:—

The Bronze Medal.

Materia Medica and Botany.

Hours from Ten till One.

1. Define the following:—epidermis, cuticle, hair, gland, stoma, vitta, lenticel, sting, herb, shrub, spine, and tendril.
2. Describe the general properties and structure of the cell-membrane or cell-wall.
3. Give a general sketch, in writing, of the distinctive characters of the stems of acotyledonous, monocotyledonous, and dicotyledonous stems.
4. Define the following:—bract, inflorescence, pollen, placenta, thalamus, ovule, seed, and germination.
5. Describe the physical and chemical characteristics of virgin scammony; mention the substances commonly employed to adulterate it, and the means by which such adulterations may be detected.
6. How is aloes obtained in the greatest state of purity? Describe the distinctive characteristics of socotrine, hepatic, and Barbadoes aloes.
7. What are the distinctive characters of aconite and horse-radish roots? Give the botanical names of the plants yielding them, the natural orders to which they belong, and state their properties, active constituents, and official preparations.

The Silver Medal and Certificates.

Botany.

Hours from Ten till One.

1. Describe the different kinds of woody tissue, and mention the plants and parts of plants in which they are respectively found.
2. Describe the structure of the bark of a dicotyledon, and show how it differs from the so-called bark of a monocotyledon.
3. Define the following terms:—decurrent, amplexicaul, connate, pinnate, pinnatifid, ligule, decussate, conduplicate, serrate, mucronate, pedate, and equitant.
4. What is the fruit? How would you distinguish small fruits from seeds?
5. Give the essential characters of the following natural orders, and enumerate the official plants which they respectively contain:—Cruciferæ, Malvaceæ, Umbelliferæ, Atropaceæ, Scrophulariaceæ, and Liliaceæ.

Materia Medica.

Hours from Two till Five.

1. What are the official substances in the British Pharmacopœia derived from the Menispermaceæ? Describe their botanical and geographical sources; their physical and chemical characters; and enumerate their official preparations.

2. What are the botanical and geographical sources of jalap? Describe the physical and chemical characteristics of the official jalap and of Tampico jalap; and show how jalap resin may be distinguished from scammony resin.

3. Describe the physical and chemical characters of nux vomica seeds and bark. Mention the characters by which the latter may be known from cusparia bark; and enumerate the official preparations of nux vomica and their respective doses.

4. Give the general characters and botanical sources of areca nut and larch bark, and mention their uses and official preparations.

5. Describe the characters of croton seeds; state their botanical and geographical sources; the manner in which croton oil is obtained, and the differences between East Indian and English croton oil.

The President having distributed the prizes to these gentlemen, called upon Professor Attfield to present his report.

Professor Attfield's Report on the Practical Chemistry Class.

Professor Attfield said he should, as usual, take as the basis of his remarks, regarding the class of practical chemistry, the report which he had had the honour to present to the Council at the close of the last session. During that session 93 pupils had attended the class, the average period of work being nearly four months each pupil. Those figures, however, scarcely conveyed an adequate idea of the amount of time which the students had spent in the laboratories, because some of the gentlemen had studied two or three days a week, or two or three hours daily; he would, therefore, endeavour to present the results in a different form. Thus, supposing it were the practice for every student to work the whole of every day; then, during last session, the average period of work of each pupil would have been 2·8 or nearly three months. Again, supposing that all students worked for three hours a day (which was now the usual time given to practical chemistry by the junior students, who found, if they worked all day in the laboratories, they had not sufficient time for their other studies), then the 93 students would have worked for no less a period, on the average, than 5·6, or nearly six months each. He did think it was a matter for congratulation, that inasmuch as the Minor examination could be prepared for, and was prepared for by the great majority of the many hundreds of candidates who now annually presented themselves, in one month or perhaps two repeated one-month courses of instruction—he could not say education—and that the majority of candidates did successfully pass the Minor examination after such a preparation, considering this fact, it should be a matter of congratulation to the Council and members of the Society, who had spent so much effort and money in the cause of real education, to find that last session so many as eighty or ninety students deliberately, and knowing what had just been stated, came to the Society's lecture room and laboratories, and spent no less than five months in gaining their education. If they could only get the chemists and druggists throughout the country who were interested in this matter, and who employed assistants and apprentices to recommend their young men, even as a matter of investment, to study, not for single months in all the subjects, but after working thoroughly at "Prescriptions," "Practical Dispensing," and "Pharmacy" in the shop, to then undergo at least a five months' course in theoretical and practical chemistry, botany, and materia medica, then the Society's school and the two or three schools at present open in the provinces might not only become self-supporting, but in time they might hope to arrive at what was equivalent to, if indeed not actually a compulsory course of five months' study, before the Minor examination could be passed. And when that was accomplished, it was to be hoped there would be found in pharmacy a sufficient demand for a longer course to justify the Council in reverting in the Society's central school to a ten months' course of lectures. He felt confident that such a time would come, though it might be distant, and there would then be a few, or at all events a larger number than now of gentlemen, who, while remaining in pharmacy, would devote two or even three years to the prosecution of their studies, and so be able to conduct pharmaceutical research. Thus only would they keep abreast in real education, and in the highest walks of pharmaceutical science, with the pharmacists of other countries in Europe and America. He had already referred to the attendance last session as being very good, under the existing limited demand for even such a moderate educational course as the Council had organized, and added on that point that the absence columns in the attendance book were only about 15 per cent. of the whole. He was also glad to report that the quality of the demand for chemical knowledge had greatly improved during the past two years, and especially during the past session. Three and four years ago he was constantly met in the classes by that disheartening question to any teacher really anxious to educate, "Will this be wanted for the examination?" But he was glad to say it was not so now. At that time, if he set certain students to make, say, oxygen gas or chlorine water, and returned in a short time expecting the whole affair to be in operation, he would find the apparatus dismounted, and no chlorine water made. On looking into the matter it would appear that the apparatus was so badly constructed that the chlorine, instead of going into the water, had all escaped into the air. On mildly but firmly suggesting that the operation should be repeated until it was successful, he would be met with the argument, "Well, but if I have not succeeded in making chlorine water, I know how to make it, and the very fact of my failure has so impressed the thing on my memory that I am sure no examiner could puzzle me on the subject." Of course, he had had to admit that this argument was sound so far as it went, but at the same time reminded such students that if they conducted all their studies on the same principle, although they might perhaps pass an examination in honours, they would not be able to carry on such operations as they might be called upon to perform in the course of business; that, still worse, they would be sailing under false colours, their moral perception would be damaged, and their sense of right and truth would ultimately be completely destroyed. To have to make such statements, and indeed to have to entertain such matters at all, was very disheartening to a teacher; but though he had met with them repeatedly three years ago, and still oftener four years ago, they had scarcely made their appearance last session, and hence he was able to say that the quality of the demand for instruction was improving. He would repeat the statement, that those who had come to his classes had been men who knew perfectly well that they could, so far as preparation for the examination was concerned, have obtained all that was necessary in a much shorter space of time; but, with their eyes open, they had preferred to come to the classes instituted by the Society, and to attend for five months, in order to obtain such knowledge as should be useful to them, not only when before the board examiners, but in their after life. The pupils who attended for the short periods were generally men who had previously worked at practical chemistry, or whose short special term was only an instalment of a long period. At the close of the session the examination for prizes was duly held, and various actual operations conducted, extending over two days. The candidates were permitted to use books or memoranda, for it was not his province to test the men's memories. He would briefly state the four operations required to be performed—1. Of what official *pilula* are the accompanying "two pills" composed? (That sounded pharmaceutical, but it was really chemical.) 2. What salts are present in "the aperient medicine" supplied to you? 3. How much sulphur is contained in the accompanying specimen of "impure precipitated sulphur"? 4. Ascertain the proportion of real acid in the sample of "diluted hydrocyanic acid." There was at the foot of the printed paper a note which was meant to be very suggestive, stating that manipulation as well as results would be scrutinized, because a man might hit on the right answer to a question by what was called a "fluke," but unless he were a good and thorough worker, he could not properly conduct operations under the eye of his examiner. Even in examinations in practical chemistry it was quite possible for a man to give an hour's sound work to a task, and then not be quite so near the truth as another man who had finished all operations in a quarter of an hour, and jumped at a conclusion; but still he who was not quite so exact in the result would be infinitely more worthy of reward. There were nine competitors, a smaller number than usual, owing to the fact that by a regulation passed last year the minimum period of study qualifying a student to compete was five months. Heretofore, three full months had qualified a candidate to compete for a certificate, and five for a medal. Under this regulation, only eleven qualified students remained in the laboratory at the end of July, and of these nine presented themselves, one retired, and three obtained less than 60 marks, 100 being the standard. The remaining five obtained places as follows. The first was a student, who, if he might be permitted to say so, was not a brilliant man; not one of those who, as had sometimes so appropriately been said, went up like a rocket and came down like its stick; but a plodding man, who, since he had finished his work at the end of the session, had been to South Kensington and taken a scholarship at the College of Chemistry. This gentleman obtained the full standard number of marks, 100, which he believed was the first instance of such a distinction in the laboratories since he had been Professor of Practical Chemistry. This first prizeman was Mr. Arthur Pearson Luff, whose name had already more than once been heard as a prize taker. Next to him came a student who had gained more than the number of marks qualifying for a silver medal, but there being only one of silver, he has to be content with a bronze medal. This was Mr. W. A. Gostling, who obtained 90 per cent. of the full number of marks. The next candidate's work was perfect as far as it went, and he, Mr. A. F. Sainsbury, having obtained 75 marks, would receive the second bronze medal. Then came two gentlemen who obtained certificates of merit, Mr. A. J. Carter with 70 marks, and Mr. W. A. Thirlby with 65.

The following were the questions for this examination:—

Practical Chemistry.

Hours—Ten to Five each day. Books and Memoranda permitted. Standard Number of Marks, 100.

1. Of what official *pilula* are the accompanying "two pills" composed.
2. What salts are present in "the aperient medicine" supplied to you?
3. How much sulphur is contained in the specimen of "impure precipitated sulphur" placed before you?
4. Ascertain the proportion of real acid in the sample of "diluted hydrocyanic acid."

Note.—Manipulation as well as results will be scrutinized.

The Herbarium Prize.

Professor Bentley, being requested by the President to make his report with regard to the Herbarium Prize, said he need scarcely remind young students that prizes were given each year by the Council for the best collections of British plants. He was sorry that on the present occasion they had not had more collections sent in for competition, as nothing could be better practice for, or more useful to, young students in the country than spending the early hours of the morning in collecting plants. A great deal had been said, and with truth, as to the difficulty which apprentices had in carrying out such an enterprise, but at the same time, although he did not like to speak of himself, he knew perfectly well that nearly all his knowledge of botany had been gained between the hours of four and eight in the morning, and therefore he would urge upon all young apprentices the importance of thus practically making themselves acquainted with the study of plants. He regretted that only one collection had been now sent in, and hoped that this would be the last time he should have to make such an announcement. It might, perhaps, be accounted for by the fact that for several years collections of very high merit had been forwarded for competition, and he was afraid at the time that this might act as a discouragement to others, from the idea that, unless they could reach an equally high standard, it would be useless for them to attempt to compete. He hoped that feeling would not prevail in future, because, whether a silver or bronze medal, or a certificate was awarded, in any case it was a considerable distinction, and was well worth striving for. He had now to announce that the Council had, on his recommendation, awarded the bronze medal to Mr. Thomas William Nettleship, an apprentice, for his collection; and he had honourably obtained, and well deserved, such a distinction. In conclusion, Professor Bentley said that young students, in collecting plants, should bear in mind that not only the number of specimens should be attended to, but that the merit of the collection, in a great measure, depended on the character of the specimens collected, and he would therefore urge particularly on all those engaging in this work, not only to strive to obtain a large number of plants, but also to look particularly to the fact that those specimens should be properly named;

and that they should be good typical specimens—not a leaf to represent a species, or a leaf and a bad flower, or a plant without fruit—but a specimen which exhibited in itself all the characteristics of the species.

The Pereira Medal.

The Pereira Medal had been awarded to Mr. Arthur Pearson Luff, to whom the President now presented it, adding a few kindly words of congratulation.

The following were the questions for this examination:—

The Pereira Medal.

Hours—Ten a.m. to One p.m.

CHEMISTRY.

1. How would you determine the composition of water? Explain minutely the apparatus used for its synthetical and analytical examination.

2. What are the simplest forms belonging to the regular or cubic system of crystallography? Name some of the substances whose form may be referred to this division.

3. Describe and give the methods for preparing the following:—the hydride, chloride, and alcohol of the methyl series. The hydride, iodide, and carbonate of the ethyl series.

4. How would you separate gold and platinum from a solution containing the two metals?

BOTANY.

Hours—Two p.m. to Five p.m.

1. Give the botanical character of the sugar cane, and a short account of its natural history.

2. Are the starch granules of wheat, barley, and maize identical in their appearance, and, if not, how do they differ?

3. Name and describe the various forms of æstivation, with an example of each.

MATERIA MEDICA.

1. Socotrine, Barbadoes, and Natal aloes each yield an aloin: describe the action of nitric acid on these aloins respectively.

2. State if Aconitum napellus and Aconitum ferox yield the same alkaloids, and describe the method of preparing them.

3. Describe the manner in which cochineal is cultivated, and give the natural order to which it belongs.

The Prize of Books.

The Prize of Books, competed for by those who had passed the Minor examination in honours during the year, was presented to Mr. Arthur Pearson Luff.

The following were the questions for this examination:—

The Prize of Books.

Hours—Eleven a.m. to One p.m.

State the best method of dispensing the following prescriptions, assign reasons for the same, and write the labels in suitable language:—

℞ Potassii Iodidi
Potassii Bromidi āā gr. xv.
Ferri et Quin. Citrat. gr. xxx.
Sp. Chloroform. ʒij.
Aquæ ad ℥vj.

M. ft. mist cujus cap. cochleare mediocre ex aquæ vel vini semicyatho vinoso, bis terve die per septimanam integram.

℞ Ext. Nucis Vomic. gr. $\frac{1}{2}$.
Ferri Sulphat. gr. i$\frac{1}{2}$.
Pulv. Rhei gr. ij.

M. ft. pil. ter quaterve die inter cibos sumend.

State specific gravities of chloroform, sp. ætheris nit., alcohol, spiritus rectificatus, and spiritus tenuior.

Describe and explain the B. P. process for making pyroxilin.

State the B. P. processes for making syrup of rhubarb and syrup of tolu.

State the B. P. process for making Linimen:. potassii iodidi c. sapone, and suggest any improvement that might be made.

The Jacob Bell Memorial Scholarships.

The President then announced that the Jacob Bell Memorial Scholarships for the Session had been awarded to Mr. William Henry Vernon and Mr. George Green.

The following were the questions for this examination:—

Hours—Four to Six p.m.

CHEMISTRY AND PHARMACY.

1. State the action of nitric, sulphuric, and hydrochloric acids upon metallic iron, and show the nature of the changes which occur by equations.

2. How would you make liquor potassæ and liquor plumbi subacetatis? By what methods would you determine the purity and strength of these preparations?

3. Write the composition, in symbols, of sulphate of copper, sulphate of zinc, nitrate of lead, nitrate of mercury, red precipitate, and red lead.

4. Describe all the processes that you know by which oxygen may be prepared. State the properties of this element.

BOTANY.

5. Describe the following:—"Corm, bulb, rhizome, tuber, tubercle, perianth," and give examples in support of your definition.

6. Describe minutely the flowers of the common "buttercup, daisy, and crocus."

Hours—12 to 3 p.m.

Latin.

1. Translate the following into English, and parse the concluding sentence of the quotation—

"At domus interior gemitu miseroque tumultu
Miscetur; penitusque cavæ plangoribus ædes
Femineis ululant; ferit aurea sidera clamor.
Tum pavidæ tectis matres ingentibus errant,
Amplexæque tenent postes, atque oscula figunt.
Instat vi patria Pyrrhus; nec claustra, neque ipsi
Custodes sufferre valent."

2. Translate the following into English—

Resina flava aut ex flavo fusca, opaca aut diaphana, fragilis, in fractura nitens, manu tractata emollescens, odoris terebinthini, in spiritu fere tota solubilis.

Arithmetic.

3. Reduce to decimals $\frac{7\cdot75}{9}$ of $\frac{2\frac{1}{2}}{2\frac{7}{9}}$ of $\frac{20}{31}$.

4. Show that if $1\frac{1}{12}$, $2\frac{2}{15}$, $3\frac{3}{20}$, $4\frac{4}{27}$ be added together, (1) as fractions, and (2) as decimals, the results coincide.

5. If 15 horses and 148 sheep can be kept 9 days for £75 15s., what sum will keep 10 horses and 132 sheep for 8 days, supposing 5 horses to eat as much as 84 sheep?

English.

6. Write from 30 to 40 lines on the value or otherwise of competitive examinations.

*French and German.**

7. Translate into English the following—

"Vous fûtes spectateur de cette nuit dernière,
Lorsque, pour seconder ses soins religieux,

* The candidate is at liberty to choose French *or* German. He is *not* required to show a knowledge of *both*.

Le sénat a placé son père entre les dieux.
De ce juste devoir sa piété contente
A fait place, seigneur, aux soins de son amante ;
Et même en ce moment, sans qu'il m'en ait parlé,
Il est dans le sénat, par son ordre assemblé."

8. Render into good *German* the following sentences—He has lived in the country. She has dwelt in town. It has rained all day. We have danced, and you have laughed at it. They have had a good father, and have always loved him.

The Hill's Prize.

The Vice-President (Mr. Alexander Bottle) said the Secretary had put into his hand a list of prizes which he probably thought the President would prefer not to read. It would be within the recollection of most of those present that a year or two ago Mr. Hills invested a certain sum of money as a fund, out of which to present a prize to the best man at each of the Minor examinations, and though his well-known liberality was exceeded by his modesty, it was but right that the names of those who had obtained these prizes should be mentioned. They were as follows :—Frederick Hearne, James H. Spencer, Evan John Howell, Alfred Wood, James West Knights, Alfred Coleman, Edward R. Marsh, John Overton, Charles R. Riley, Jabez Abraham Jones. He would only detain the meeting one minute longer, to assure the students that prizes of equal value would be awarded next year, and to urge upon them to be unremitting in their efforts. They had heard from Dr. Attfield that one student had actually attained perfection, and nothing short of this should be their aim.

The Inaugural Sessional Address.

The following address to the students about to commence their studies in the school of pharmacy was then delivered by Mr. Richard William Giles, of Clifton :—

Gentlemen, — Students of the Pharmaceutical Society's School of Pharmacy,—

My first pleasing duty is to bid you heartily welcome to these Halls. Welcome in the name of the School, of the Society, and of the brotherhood of pharmacy throughout the kingdom, who look to you and to those who may come after you with like aspirations, to take up and to carry on the work in which they are now engaged, to sustain the edifice which they have laboured to construct, to advance the standard of English pharmacy, and to bear it to the front in friendly emulation with the civilized nations of the world. But better welcome than words can give may be read in the ample provision here made for your guidance in those studies which are the foundation of scientific pharmacy. You have but to survey the museum, the library, the lecture-room (in which we are now assembled), and the laboratories of this institution, to see what infinite pains, what generous expenditure, what practised experience, have been bestowed to make your welcome complete. You have yet to learn what accomplished teaching animates the whole, and to experience the kindly co-operation of the professors, which I undertake to assure you will not fail those who diligently follow the course of instruction marked out for them. These preparations are all for you, and the only return desired is that you shall so employ them that they may contribute to your own happiness, honour, and prosperity. The constant aim of this Society, the single purpose of its School, the only use of these sessional addresses (if, indeed, they may aspire to any usefulness), is to promote pharmaceutical education, and thereby to increase the welfare of the pharmaceutist, and to give improved accommodation to the public.

It was not always so. There were dark days before the Pharmaceutical Society rose to be a power. It may encourage you to appreciate the opportunities which you enjoy, and stimulate you to make good use of them, if I briefly compare the conditions of a few years ago with the circumstances of the present time. Pharmacy had probably sunk to its lowest point of degradation ; its professors were commonly wanting in the training necessary for conducting it scientifically ; an opinion (still unfortunately prevalent) that a smaller capital sufficed to establish a chemist's shop than was required for the stock of other trades, attracted men of small means ; and, so far as my observation allows me to judge, the quality of the chemists of that day was inferior to that of those who preceded them ; the shops were more numerous and less important, and the business was done upon a less liberal scale. Happily *Latin* was popularly supposed to be indispensable, and although the quantity was usually homœopathic and the quality "canine," this superstition was the sole foundation upon which pharmacy could rest its claim to a status above the unscientific trades, and should accordingly have secured for itself our respect and veneration. It was an ungrateful return for this good service that the first Pharmacopœia in the compilation of which the pharmaceutical body were officially represented should have proved the occasion for abandoning the Latin text for the vulgar tongue ; but in the meantime our classical pretensions had been preserved by the institution of the Preliminary examination.

In those days, pharmacy had no corporate existence; its members were not characterized by gregarious instincts ; they might properly have been described as solitary and sedentary ; they had no central home, no wandering conference ; there was no school where the art and mystery of pharmacy was scientifically and systematically taught ; there was no pharmaceutical literature, there was no demand for any ; each man worked out the narrow problem of his life beneath his own peculiar vine and fig-tree, and left his neighbour to do the like.

Yet this period of deep depression could produce such men as Allen, Bell, Paine, Morson, Deane, Savory, Squire, and others of whose names we may be justly proud. Where there is a will there will always be found a way, and it would be impossible to refer you to a more pleasing illustration of this good old proverb than the autobiography of the late lamented Henry Deane. Truly there were giants in those days, but the average stature was the measure of a dwarf. It is not, therefore, wonderful if the general body of chemists and druggists failed to commend themselves to the confidence of the medical profession ; they also failed to impress the public with any exalted respect for their attainments. The natural consequence was, that they held a precarious position, and were in chronic fear of hostile legislation. A panic, produced by an accidental aggravation of this state of apprehension, led to the establishment of the Pharmaceutical Society, and now, after a period of thirty years, we are met to-night to carry out that system of compulsory qualification (the bugbear of my youth) which has been brought into operation mainly by the instrumentality of the Society which at first sight seemed intended to thwart it. We may truly say, "Tempora mutantur"; may we not thankfully add, "Nos mutamur ab illis"?

It would be foreign to our business this evening, to follow minutely the political history of the Pharmaceutical Society—suffice it to say that it is the history of the progress of English pharmacy in its era of greatest activity; but I am sure that you will bear with me while I pay a just tribute of gratitude to the clear-sightedness of the distinguished men who led that important movement, and who had the sagacity and elevation of mind to make *education* the basis of their Association. They had the wisdom of unselfishness, and instinctively perceived that stability might be given to a temporary combination by identifying it with a scheme of permanent public utility. In the natural course of events there are but few of them who now remain to us, but amongst the many treasures of this Institution there are none more cherished than the life-like portraits of those worthy founders of scientific pharmacy in England, whose names are hallowed memories to us, and will long survive as household words familiar to those by whom we, in our turn, shall be succeeded.

But I must not grow garrulous over reminiscences of the past, forgetting that you are young and that your interest is in the future, while it is many years since I sat where you now sit, when these memories were passing events. But for this I would fain dwell a little longer upon the school as I then knew it, upon the many valued friendships which date from that well-remembered session, and the professors whom I learnt to revere so truly—Fownes, Pereira, Thompson, Redwood! It is no small honour to our Society to be able to connect its traditions with these distinguished names; it was a priceless advantage to its early growth to have had such men associated with it. It is time, however, to turn from these retrospects to more practical concerns, and to consider how I may best interest you in the work that lies before you, and how I may encourage you to make profitable use of the coming session, in which you doubtless hope to complete your technical training, and to accomplish your preparation for a life of honourable duty.

It is customary upon occasions similar to the present for the speaker to depict in glowing colours the attractions of science, and to expatiate upon the exalted pleasures which reward those who penetrate into the ever-varied wonders of nature, and by diligent observation of phenomena, which to indifferent observers appear incongruous or contradictory, to resolve them (as the tendency of all scientific research is) into common laws of simple harmony. No loftier exercise of the intellect can be imagined than this; it raises humanity to the highest eminence to which it can attain—the appreciation, namely, of the works of God, and of the unity and beneficence which his works unfold. By such example the student is appropriately exhorted to enrich his mind also with the knowledge which these pioneers of science have accumulated for the common good.

Such language would of right belong to one who had traversed the wide domains of science, and drank deeply of its ennobling springs, or, more distinguished still, had extended its domains in paths peculiarly his own. He alone could touch with magic power those sympathies within you which no weak echoes of his nobler strain may hope to stir. But candour compels me to confess that I have not trodden these sublime heights, and I stand abashed at the presumption of attempting to portray them. I dare not soar with borrowed wings, but rather will I invite you to wander with me in the lowly plains, talking at ease of things familiar, and hoping that even so you may find encouragement to do with all your heart the work to which your hand is set.

First, then, let us make sure that you rightly understand the objects for which you are here. I take it for granted that it is your intention to make pharmacy your vocation, and that you will be willing to devote a few moments to the consideration of its character and scope before we go on to speak of the scientific education which is a necessary part of its preliminary training.

Pharmacy is a trade. This was well and honestly said by Mr. Ince, at Nottingham. Pharmacy is a trade—more momentous than other trades—charged with graver responsibilities—demanding a higher morality, and qualifications similar to, if not absolutely identical with, those which belong to the professions—but still a trade; and it will be well for the comfort of those who propose to follow it that they should learn from the first to accept it on these terms. In spite of sentimental yearnings after the dubious status of a profession, it is satisfactory to know that men who have been the brightest ornaments and the most eminent representatives of pharmacy have frankly accepted this position, and *we* may do the like without compromising our dignity or proving recreant to our order. The responsible nature of our business imposes upon us a professional standard of ethics, and it follows that this demands a corresponding elevation of status; but it would expose us to merited derision, if we sought to invert the natural order by which these results are attained. The status of pharmacy will be best raised by the diffusion of a higher educational tone amongst us, which must, in the end, command respect.

Again, pharmacy has a scope wider than the duties of the shop, though even these should be extended beyond their customary restricted range; it makes visible pretensions to the sciences of chemistry and botany, and must be gauged by its fulfilment of these pretensions. Although of late years we have made some progress, we have not done more than keep abreast of the age, which has equally awakened to the importance of scientific knowledge. It now forms part of the curriculum of all good schools, and is the most characteristic feature of the educational activity of the present era. As the results of this change become developed, we may anticipate that every well-educated Englishman will possess at least an elementary knowledge of the physical sciences; and a relative proficiency in those sciences which are allied to your calling will be required of you. The pharmacist of the future will be expected to know and to be able to assist others in exploring the flora and geology of his neighbourhood, and generally to take part in its local scientific associations. He will no longer be able to assume a virtue if he has it not, for his pretensions will be seen through and derided. He will be forced up (or trodden down) by the pressure of the crowd. He must be competent to act as the intelligent coadjutor of the physician, assisting him in investigations demanding the application of chemistry, which is *his* legitimate department. He will frequently be consulted upon questions relating to the chemistry of common life: in sanitary matters, such, for example, as the chemistry of disinfectants, he is the natural adviser of the medical profession and of the public. Minor analyses will be brought to him, which would probably not find their way to the public analyst, while this appointment is itself open to him if sufficiently qualified; and I hold that under a satisfactory condition of pharmacy it would be for the public convenience, as well as for our credit and advantage, that it should generally be filled by a pharmaceutical chemist There are already instances in which it is honourably held by members of our body, notably in my own city. Such are some of the considerations which challenge your attention at the time when you are about to qualify yourselves—not for the pharmacy of the past, but for the advancing pharmacy of the future. It seems probable that greater changes are impending than we have yet seen, and you will do well to lay your foundations wide and deep in preparation for the superstructure, whose exact form and dimensions you cannot with certainty foresee.

With these prospects before you, you are about to enter upon a short course of systematic study—so short, that without the previous preparation which this school, in common with every advanced school, presupposes, it would be altogether insufficient, and under the most advantageous conditions it can only be regarded as a bare minimum. It is understood that you have passed a satisfactory Preliminary examination in the usual school subjects, that you therefore possess an average degree of intelligence, and have *learned how to learn* by the mental discipline inculcated at some good school. The test of the Preliminary examination is as indulgent as the case permits, perhaps too lenient; but it is to be hoped that the Society will be enabled before long to delegate this office entirely to such hands as will give assurance of efficiency; for it is obvious that the subjects of the Preliminary examination are no part of the curriculum of a pharmaceutical education, but that it is an ordeal to be passed as a condition precedent to apprenticeship. It is further assumed that you have spent an apprenticeship, or at least some considerable part of it, in a pharmacy where you have already become familiar with the drugs, chemicals, and preparations ordinarily employed in medicine, that you know their physical characters, and have some general acquaintance with their properties and behaviour, *e. g.*, as to solubility, crystallizability, etc., and that you have learnt the officinal names, which more or less accurately indicate their chemical constitution and natural relations. In all probability most of you have extended this information, acquired in the routine of shop duties, by some amount of study in the way of scientific reading and attendance at lectures. In fact, you have made with little effort considerable progress in the vocabulary of chemistry and botany, but you want the grammar which shall consolidate these disconnected words into a living language. If you have come here, as I trust you have, honestly bent upon learning your grammar like good boys, that you may speak hereafter like wise men, I venture to promise that you shall not go away disappointed. I hope that you will make this session memorable by your attention to its duties, that you will be constant in attendance at lectures, never permitting yourselves to miss a single one, for it breaks the thread and interrupts the continuity (as I know by bitter experience, for did I not miss one myself?), that you will work diligently in the laboratory, following the course which is as systematically progressive as the courses of lectures, and that you will not fail to supplement these recreations—for such you will find them—by steady reading at home in connection with the subjects of the day. I beseech you not to neglect this last exercise, for you can never read to so much profit as when the subject is vividly impressed upon your senses by the tangible operations of the day, and when it is presented to your apprehension in its proper order of sequence.

I would not be the one to press study upon you to an excessive extent, for I believe there is true wisdom in the homely saying that "All work and no play makes Jack a dull boy;" but it is equally true that there is a time for all things, and this is pre-eminently your time to study, for in all probability it is the golden opportunity which will never return to you again. Ten months, as I have said, is a very short period in which to acquire that moderate amount of proficiency in pharmaceutical science absolutely necessary to enable you to make a respectable figure in after-life. If any one amongst you thinks differently, let him reflect how grievously he would depreciate the dignity of pharmacy, which it should be our aim to exalt. What status could we dare to claim on the score of so much scientific education as it would be possible to compress into a period of six—or would you say three months? Every good thing is worth its price, and none may hope to win the laurel without the dust of the strife. But this is not strictly true; there are, alas! those who do this, who aspire to the laurel without braving the dangers of the fight, and unfortunately they do often succeed in carrying off some dead leaves, which they wear with the complacency of conquerors. You will be at no loss to understand that I speak of those misguided youths—students we cannot call them—who give themselves up to the manipulations of the professed "crammer," and conspire by means most unworthy to elude the penetration of the examiners, and to obtain a certificate of qualifications which they know full well they do not possess. The object of examinations is to exclude the unqualified; the scarcely disguised object of "cram" is to pass the unqualified through. Whether at our own school or elsewhere a term of one, two, or three months is totally inadequate for the preparation which pharmacy requires of its disciples, and utterly insufficient to afford that amount of qualification which public opinion demands. Every school is, of course, subject to be abused by candidates who—caring only for the specious pretensions of a certificate—enter for these short periods, and it is only when the school wilfully lends itself to the abuse that it can fairly be held responsible. The cramming system does this, and is working so much mischief to *bonâ fide* education, that it is the bounden duty of all honest men to unite in stamping it out. Its operations are widespread; wherever examinations prevail (and where do they not?) this noxious parasite springs up and poisons the air. In the universities, the professional colleges, the army, the navy, the civil service—everywhere the evil is rampant and, it must be admitted, triumphant; and everywhere the wail of examiners, cheated with open eyes, goes up. To show that our examiners are not more easily imposed upon than others, I will read a short extract from an article upon "cramming" in a popular periodical :—

"The disgusted examiner gradually recognizes that he is not conversing with George Griffin, jun., but with Dr. Varnish, M.A., etc., etc., who speaks all languages, knows something of everything, and is growing rich apace by preparing young gentlemen for the civil and military service of their country. Mr. Griffin is there in the body, certainly, with pink ears and heated forehead, and his preceptor is as undoubtedly absent; but nevertheless the examiner cannot but feel that all his efforts are as thoroughly baffled as if the young man were a medium, and Dr. Varnish held him under some as yet unknown mesmeric influence. There is no getting at the lad's real brain, no finding out what he will be, when at no distant date he shall have forgotten Varnish and all his works. As it is, that subtle instructor of youth has armed him at all points; he is a pattern pupil, and has absorbed exactly such information, and no more, as will help him through the ordeal before him. If caught tripping on one subject, he is comfortably bolstered up on all the rest, and as the defeated examiner grudgingly sends in his name at the top of the list, he is forced to acknowledge with a sigh that Varnish is a very clever fellow."

This graphic sketch conveys the painful impression that the newly-developed idea of universal examinations, which was doubtless expected to give encouragement to education, has had a contrary effect; that it has diverted attention from education to fix it upon examination—that it has overwhelmed the substance in its own shadow, and invested the shadow with the semblance of reality. The pharmaceutical crammer is equal to the occasion; he tempts unwary youths (ignorant, let us hope, of the full extent of the deception in which they are about to take part) with the flattering assurance that he will qualify them for the examinations in five weeks! and forthwith commences a carefully digested course of unmeaning jargon, of which, I am told, the following is a specimen, "Three—one—five, catch 'em alive; one—two—three, out goes she"! And this, by some inscrutable property of association, is said to enable the candidate for pharmaceutical honours to remember (till next examination day) the respective constitution of carbonate of magnesia and carbonate of zinc! but for all useful purposes, for all that makes knowledge convertible into power to be utilized in after-life, he is as ignorant as he was before.

Lest you should ever be tempted to avail yourselves of these meretricious devices, and to wander from the rugged track which leads to knowledge in pursuit of some softer, enervating road, I will furnish you with a talisman of power, if you will only trust to it. I pray you in your hour of weakness to remember—and not to pervert—the old, the wise, the manful maxim, "Labor omnia vincit."

It is told of a Bristol worthy, that he was one day found seated in a well-stored library, deep in perusal of a book, and being complimented by his visitor upon this evidence of tastes not previously suspected, he is said to have replied in reproachful accents, "Yes, Mr. D., here I sits all the day, and I reads and I reads, *but nobody is any the wiser.*" If nobody was any the wiser, we may at least hope that nobody was any the worse, which is more than can be said for the votary of "cram." He is none the wiser for a miserable mockery of education, but he is the worse for the fraud in which he has been an accomplice, for the dishonour which he does to his profession, and for the deception of a career based upon false pretences.

Some hope may be derived from an explanation which is at least plausible of the present excessive development of pharmaceutical "cram;" it might have been foreseen that the substitution of compulsory qualification for voluntary, would create a panic amongst those who had committed themselves to the vocation of pharmacy without sufficiently counting the cost. In spite of frequent warnings and repeated opportunities of grace, many young men now find themselves in this false position, and are dismayed at the prospect of examinations which they would not allow themselves to be persuaded would become obligatory upon them. They feel that they are not prepared to pass legitimately, and they jump at any help that offers without criticizing it too closely, like drowning men catching at straws. If this be a just interpretation of the present unsatisfactory aspect of pharmaceutical education which embarrasses our examiners and disheartens our professors, we may hope that the magnitude of the evil at least is temporary, and will die out when the present crisis is passed; but if this hopeful anticipation should not be realized, strong measures must be taken to put it down. We cannot afford to sacrifice the labours of thirty years to an ugly fetish, nor will we consent to do it. The obvious remedy is the establishment of a compulsory curriculum of education at recognized schools as a condition of examination. The principle is generally adopted elsewhere; it prevails at the old universities, at the medical schools, at the more recently established Veterinary College, and in the Continental schools of pharmacy; and there is no feature of our system which our Continental brethren view with so much disapproval (not to say contempt), or regard as such a fatal blot upon its efficiency, as the absence of a prescribed course of study. I cordially agree with them, and speaking here without official reserve, and without the fear of implicating the higher powers (I may also say, without much fear of offending them), I express my deliberate conviction that a compulsory curriculum must sooner or later be adopted, and the sooner the better. This, and this only, will solve the difficulties of what we have been pleased to call "provincial pharmaceutical education," but which should be more broadly spoken of as "national pharmaceutical education," without distinction of place; and it may even turn out that "cram," over which we now groan, may prove to be a blessing in disguise by hastening this consummation so devoutly to be wished.

It may seem to you that I have wasted a good deal of virtuous indignation; that this outcry against "cram" may be very just, but that it is out of place upon the present occasion, and you may be disposed to resent the application of such a homily to *you*. My young friends, I am not sure that you are all as virtuous as you look, though I sincerely hope that your "ingenuous countenances" do not belie you. There are degrees in "cram," and, though I may not suspect you of its barefaced enormity, you may perchance be tainted with its vices in some milder degree. I ask you, then, pointedly—What brought you here? Did you come impelled by an Englishman's sense of duty, by the honest desire to qualify yourselves for your future life, to do that which lies before you in a manful and exemplary manner,—and in due time to submit the validity of your qualification to the test of fair examination? Did you so? If you can answer this home question.

with a loyal "Aye"! then I am authorized in the name of this Institution to bid you the heartiest God-speed, to lead you to its most favoured seat, and to promise you abundant success; but anything short of this is a step on the road to "cram." If you come here making the examinations the first object of your heart's desire, and the pursuit of knowledge subordinate to that low end—then I am constrained to warn you that you cherish a mischievous delusion which is parent of "cram." You confound the shadow with the substance, and "will come to fight with shadows and to fall," in your own esteem and in the opinion of others.

It is my duty to urge you, with all the cogency which I can command, to qualify for the highest grade in pharmacy; to be satisfied with nothing short of the Major qualification, which I unhesitatingly assert is fairly within reach of all who make proper use of the opportunities of this school. It may be that the Major qualification is not absolutely imperative, that the Pharmacy Act recognizes the inferior grade, and confers upon it equal trading privileges; and if your ambition were limited by Act of Parliament, you might contend that the Minor qualification accomplished all your wishes. But this is not the language we hope for from you. To whom can we look if not to the pupils of our own School to uphold the highest standard of pharmaceutical education? The Minor qualification may suffice for some,—it is no fit goal for you; and I have addressed you to little purpose if your aspirations soar no higher. Let me once again entreat you to seek knowledge for its own sake; it will beautify that which would otherwise be merest drudgery; it will invest your daily avocations with a new meaning, and will enable you to restore to pharmacy those interesting processes which a former era relegated to alien hands while it retained only that which was monotonous. Even in the lowest view of your worldly prospects, it would be a blunder to forego the higher qualification. Nothing is more likely than that your advancement in life may be determined by the nature of the qualification you can claim, and you may hereafter bitterly lament your unwisdom if you do not avail yourselves of the present opportunity.

Let me exhort you to place confidence in yourselves, though you may be conscious that your abilities are not remarkable. The practice of holding up exceptional talent for general imitation is not only unfair but demoralizing in its effect, and I will not follow it. I have the highest respect for honest, painstaking mediocrity, and believe that we need covet nothing to which it cannot attain. 'Arma virumque' sang the poet of old, and I too will sing not of *heroes* but a *man* equipped—equipped with such weapons as this school and his own manhood can furnish; arms of proof for the battle of life—not the tinsel weapons forged only to glitter in a fancy skirmish with examiners. Be of good courage, my young friends, and take comfort from the reflection that the best, if not most brilliant, part of the world's work is done, and done well, by respectable mediocrity; and in all probability the greatest happiness as well as the greatest usefulness is achieved by those who may safely be trusted with lucifer matches on the banks of the Thames.

I may not pass over, though I can only briefly touch upon, one other topic of the hour in which your subordination as students, and your behaviour as gentlemen, are concerned. I refer to the admission of lady-students to the lecture classes of this school. It is not my business in this address, still less does it become you, to question the policy by which the internal administration of the Pharmaceutical Society is governed. Your duty is to respect the regulations which you find in force; and if it were not that ill-advised demonstrations have been made elsewhere, it might not seem necessary to allude to so small a matter. If I were to express an opinion upon the general question, it would probably be that, if the ladies were allowed to have their own way in this as they are in most other matters, the present 'Tempest' in the pharmaceutical teapot would prove to be a veritable 'Much Ado about Nothing;' and I for one can neither fear nor hope that any concessions which we may make will realize the poet's dream—

> "Pretty were the sight
> If our old halls should change their sex and flaunt
> With prudes for proctors, dowagers for deans,
> And sweet girl graduates in their golden hair."

As it is, I have but to ask you to behave towards the lady-students whom you may meet here during the session with the respectful courtesy which characterizes the conduct of a gentleman to a lady under all circumstances. The position of the lady-students is somewhat novel, and (connected with recent events) will excuse me for cautioning them that the assertion of "equal rights" is inconsistent with claims for special privileges, and they must be prepared to defer to the same discipline as other students, and to accept, without contention, the Examiners' estimate of their qualifications.

Gentlemen, I have now brought my "rustic oration" to a close. It has so far outgrown my intentions that I will not further abuse your patience by a formal peroration. I will, however, make one personal appeal to your generous impulses. The past Presidents of the Pharmaceutical Society have always been men of eminent position, and have usually brought some special qualification for their important office. The President of the present time is the most popular of Pharmaceutists, as repeated Council elections have testified. I need not remind you that an enduring popularity is not the result of accident. Mr. Hills owes the affectionate esteem with which he is regarded to a large-hearted liberality which is part of his nature, and which we will not stop to praise; but his special characteristic is the deep and sustained interest which he has ever taken in pharmaceutical education and the welfare of pharmaceutical students. It is in your power to render him the most appropriate return by making his term of office distinguished by the success of this central school of pharmacy. You can strengthen the traditions of the school, and impress the mark of your diligence upon its work, to be a model for those who come after. Thus early in your career you may do something for pharmacy, and I feel sure that you *will* do it.

I now commend you to the experienced guidance of your professors, with warmest good wishes for your success here, and for the welfare, happiness, and prosperity of your future lives.

Gentlemen,—farewell to-night! but we look to hear of you again.

Dr. Greenhow, in proposing a vote of thanks to Mr. Giles for his admirable address, desired especially to commend it to the attention of his young friends for the sound, sensible advice it contained; and to urge upon them to prepare themselves, not by cramming to pass an examination, but by honest persevering study to fit themselves for duties they would be hereafter called upon to fulfil. Their calling had been termed by the lecturer a trade, and certainly it had trade associations connected with it. It was, however, a skilled trade of the very highest order, and approached very closely indeed to the character of a profession. No doubt there had been a good deal of cramming on the part of candidates who had come forward for examination, as was evident from the fact that so many had failed on their first attempt to pass. But this was inevitable, not only when the society was first established as a voluntary institution, but still more so when by virtue of an Act of Parliament examination was made compulsory. Under such circumstances it was essential that the examinations should not at first be too stringent, but they had been gradually increasing in stringency, and with the present month a new mode of examination would come into operation, which he believed would go far to defeat the cramming system. The examination would not really be more stringent, but more practical; one which should really test the competency of candidates; the object being to ascertain, for the protection of the public, that persons intending to become chemists and druggists were really qualified for the business they were proposing to undertake. He ventured to say that the days of cram would now be over, and that in a very few months those who, actuated by less earnestness of purpose, were anxious only to obtain a qualification, would find that they could not succeed in their object without really working hard at the subjects in which they were to be examined.

The resolution having been carried by acclamation,

The President, referring to what had been said of him by Mr. Giles, said he always considered it one of his greatest privileges to be able in any way to assist the cause of pharmaceutical education, and he trusted full advantage would be taken of what had been done by the founders of the society. In his early days, there were only about three books from which information could be derived, and no institution offering such facilities for study. The young men of the present day had assistance offered by the Pharmaceutical Society, on which its founders had expended upwards of £150,000, and he hoped they would endeavour to make good use of it.

Mr. Giles, in acknowledging the vote of thanks, said he would take this opportunity of publicly thanking the Council for the honour they had done him in inviting him to address the students, his sense of satisfaction being increased by the circumstance that this occasion happened to coincide with his retirement from the pharmaceutical business. He could not but feel very grateful to them that the last act of his pharmaceutical career was one so gratifying to his own feelings.

The President drew attention to two books presented to the society by Professor Dragendorff, of Dorpat, through Mr. Greenish: (1) 'Materialen zu einer Monographie des Inulins;' (2) 'Die chemische Werthbestimmung einiger starkwirkender Droguen und der aus ihnen angefertigten Arzneimischungen;' also to a specimen of *Artemisia Cina*, presented by the same gentleman.

The Chairman announced that the next evening meeting would be held on Wednesday, November 4.

EXAMINATIONS IN LONDON.

October 9th, 1874.

Present—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Two candidates presented themselves for this examination, and failed to pass.

MINOR EXAMINATION.

Seven candidates presented themselves. *Five* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Davey, Thomas Sercombe ....Exeter.
Kempster, Frederick Augustus ...Clapham.

These names are arranged in order of merit.

MODIFIED EXAMINATION.

Twenty-seven candidates were examined. *Thirteen* failed. The following *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Black, Felix ....London.
Brown, Joseph ....Liverpool.
Edmonds, George ....Ryde.
Girvan, John ....Glasgow.
Hill, John ....London.
Hilton, Frederic Henry ....Waterloo.
Lewis, Thomas ....London.
Lincoln, Nathaniel ....Norwich.
Lloyd, James.........................Chester.
Maule, William Preston ....Chard.
Mount, James ....London.
Samuel, James Burck ....Brighton.
Wavell, Charles Hoad ....Ryde.
Williams, Thomas ....Chester.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

"*Syrupus.*"—(1) See an article in vol. iv., p. 142. (2) A formula for Lacto-phosphate of Iron and Lime will be found in the same volume, p. 610.

G.—Beta maritima.

G. C. Druce.—Pimpinella magna.

"*A Well Wisher,*" *etc.*—The grievance has been so fully stated recently in this Journal that it is not desirable at present to insert any more letters respecting it. We think that just now more may be done towards removing it by remembering that the consent of both parties is required for the completion of the bargain.

T. M. J.—'Tomes's Dental Surgery,' published by Churchill.

"*Local Sec.*"—(1) By placing them in a limited enclosure with some odoriferous substance. (2) Mr. Ullmer, Old Bailey. (3) "Burnt" linseed or nut oil.

G. Dobson.—We cannot accept the distinction you would thrust upon the Journal, of "being the mouthpiece of our rulers." Neither does any such antagonism exist as is implied by your wishing to address "those at the head of the other side." Further, what you call "impracticable" has been accomplished over and over again. Under these circumstances it is not thought advisable to insert your letter.

F. W. Branson.—We are unable to say which is the best.

Communications, Letters, etc., have been received from Mr. G. Matthews, Mr. Thorp, Mr. Armstrong, Mr. Fox, Mr. Beach, Mr. Dowman, Mr. Pitman, Mr. Fairlie, Mr. Whyte, Mr. Talbot, Mr. Barnet, Mr. Brown, Mr. Barclay, Mr. Monkhouse; J. W. W., W. J. S., L. A. R., A Young Pharmacist, Chemicus, Mac, Erin, Inquirer, Nemo, Vir pro Bono Publico, Caution.

Notice.—In consequence of the great length of the report of the Society's meetings we are compelled to postpone notice of several communications.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 263.)

UVÆ URSI FOLIA.—The leaves of *Arctostaphylos Uva Ursi* have no very remarkable structural peculiarities, and may be dismissed with a very short comment. The upper and the lower epidermis have the same general arrangement of cells, and these are pretty regular in size, excepting near the midrib. They are four to six-sided, with rounded corners, sometimes nearly round, and present when seen in the isolated epidermis, a tolerably regular pattern of rounded off squares or pentagons. There are no stomata on the upper surface. The stomata on the lower surface are curiously grouped. The grouping is determined by the network arrangement of the veins of the leaf. The guard-cells are two in number. The inner tissues of the leaf, beneath the epidermal compressed cells and superposed thickening, are several layers of vertical chlorophyll-bearing cells, and the spongy parenchyma, with the vascular system and its wood-fibres. With the wood-fibres are small square cells, each of which contains a small prismatic or lozenge-shaped crystal of some lime salt. The wood-cells are frequently stained with an astringent brown colouring matter, and form a wedge extending from the rib-bundle to the surface of the leaf.

It does not appear to be practicable to mount sections of these leaves permanently.

MATICÆ FOLIA.—The exceeding thinness of these leaves, and their tesselated arrangement, render it very difficult to make transverse sections of them, and there is nothing whatever special in the inner tissues of the leaf until we come to the structure of the midrib and veins. The epidermis is composed of small cells, and is remarkable for the small amount of cuticle substance superposed on it. It is furnished with multicellular hairs, pointed, sometimes capitate, and slightly marked with nearly round punctations on the lower surface of the leaf. The epidermis of the upper surface is very white, and composed of loose cells, with little cuticle. The structure of the midrib is somewhat anomalous, a character common in the Piper family. Four to eight vascular wedges are arranged in a loop three-quarters around a medulla situate much nearer the upper than the lower surface of the leaf. Above the portion of the medulla left exposed by the opening of the loop is situated a bundle of woody parenchyma, composed of long, square-ended cells, much thickened by a semi-ligneous substance that swells considerably in water, but does not dissolve. It would appear to be nearly pure cellulose modified towards lignin. Outside this is a small layer of parenchyma and the epidermis. Outside the vascular wedges are layers of porous parenchyma cells, and round these variously sized bundles of wood, parenchyma, and the external cells.

The vascular wedges are composed of large porous vessels; spiral vessels, with large thick spirals, sometimes one to three, right or left-handed, sometimes one right and another left-handed in each tube; and of wood-fibres and long cells containing various colouring and aromatic matters and octahedral crystals.

The parenchyma between the vascular wedges and the bundles of woody parenchyma is chiefly composed (not entirely) of large round or oval cells, much thickened and marked with bold distinct oval pits.

The structure of the midrib is thus seen to be very characteristic, and to consist really of (1) a ring composed of epidermis; (2) of parenchyma; (3) a ring of bundles of woody parenchyma, separated by masses of the last; (4) a complete ring of modified parenchyma, consisting of the porous cells described, and ordinary parenchyma cells; (5) of vascular wedges arranged in a loop; and (6) of an excentric medulla.

It may be worth while noting that the structure of the aerial stem of *Artanthe* consists of a looped arrangement of vessels, and more or less modified parenchyma, but differs from the midrib and petiole in many respects, as is quite usual.

TABACI FOLIA.—The structure of the veins and midrib, and the character of the epidermis and its appendages, are the important features in the leaves of the tobacco plant.

The cells of the epidermis are rather large, and have waved outlines. The stomata are rather large, and occur on both the upper and the lower surface, being most numerous on the latter. The hairs on the surface, are, however, the most characteristic; they are multicellular glandular capitate, with a peculiar crook or twist.

The structure of the midrib, as is well known, is remarkable for the horseshoe arrangement of its vessels and wood-fibres, and the peculiar character of the parenchymatous tissues generally.

As the plant has no very special interest to the pharmacist (unless he be a smoker), it is, perhaps, hardly worth while to go more minutely into the structure of its leaves, which have already been very fully described by other writers.

SENNA (TINNIVELLI).—The structure of the leaves of *Cassia elongata* may be taken as the structure of the true sennas, as the other species have but slight differences in details of structure from this. The upper epidermis and the lower are furnished with great numbers of small stomata, stiff unicellular pointed hairs, much consolidated and rugose; and their cells are small. Certain of the hairs spring from a slight elevation of the cuticle, composed of dark-coloured cells grouped round the base of the hairs.

The structure of the sub-epidermal layers is exceedingly simple, and of the usual type; but the vascular system is highly developed. The midrib and primary veins are of the usual character. With their woody fibre-cells are disposed, in strict linear order, great numbers of lozenge-shaped crystals of a lime salt. The secondary veins, groups of spiral vessels with little or no woody fibre, ramifying in the parenchyma of the leaves, have, however, none of these crystals; but a great number of sphæraphides are associated with them, and, more particularly, distributed in the parenchyma between the loops or interspaces of this spiro-vascular system. Having regard to the thinness of the leaves, these inorganic constituents are very numerous.

HYOSCYAMI FOLIA.—The section of the midrib presents a somewhat similar horse-shoe arrangement of the vascular system to that found in tobacco; but the investing layers, and particularly the epidermal appendages, present considerable differences when carefully compared with tobacco. The midrib is made up of spiral and annular vessels of considerable size and thickness. The associated fibre, or woody parenchyma is very slightly thickened, and with it are associated oblong cells containing an amorphous or semi-granular substance. These cells and their contents are somewhat similar to those described by me in the petiole of *Cinchona succirubra*, but nothing but chemical analysis will enable us to say how far their contents are identical.

The secondary vascular system is very highly developed, and consists of spiral vessels, which divaricate again and again until a fine net-work is produced, chiefly composed of single spiral vessels, which ultimately terminate in the parenchyma in small club or swollen ends. In the interspaces of these vessels are great numbers of exceedingly small crystals.

Stramonium. Belladonna.—Certain points in these leaves, the existence of amorphous substances in special cells similar to those in Hyoscyamus, require prolonged and careful study, and must furnish the subject of a prolonged investigation on green leaves.*

Fruits and Seeds.—The microscopical examination of many fruits and seeds is of considerable importance, both to the analyst and the botanist. The microscopical characters of many fruits, those of the Umbelliferæ and Compositæ, for example, are of the first importance in drawing up the general characters of species and genera, and in some cases will alone enable one to determine the species with any degree of accuracy. The more minute microscopical characteristics are of equal importance to the analyst in many cases, such as the adulteration of pepper with grains of Paradise, or of mustard with capsicums. Such microscopical examination as the botanist requires is usually of a very simple kind. In the case of the fruits of the Umbelliferæ, for example, it suffices to make a simple section, and view it with a very low power. The analyst, on the other hand, must make himself fully familiar with the microscopical appearance of all the tissues that enter into the constitution of the fruit or seed concerned. The fruit, of course, consists of two portions—the seed and the enveloping tissues, or *pericarp*. The latter may, following De Candolle, be divided into three groups of tissues—the *epicarp*, or their outer rind, the *mesocarp*, or middle layer, and the *endocarp*, the innermost layers. All these vary much in their relative development, the two latter most, and frequently all are so closely related that it is difficult to distinguish the one from the other. Each of these tissues has characters of its own, and should be separately examined. In the case of such fruits as have all their tissues in a soft state this is a very easy process. Mere sectionizing with a sharp razor will suffice to prepare the tissues for examination, but when, as very frequently happens, the mesocarp or endocarp is much hardened, as in the shell of the cocoa-nut and the fruits of many palms, in the fruit of star anise and the endocarps of stone fruits generally, a different and tedious process has to be gone through. We may take the cocoa-nut shell as a typical instance. Vertical and longitudinal sections are required. For the former we cut as thin a slice as possible with a fine saw (such as are sold by dealers in watchmakers' tools), and carefully rub down one surface on a fine Canada oil-stone until it has become perfectly level and smooth. We then cement it to a glass slip with hardened Canada balsam (the balsam should be just hard enough to be indented with difficulty by the finger-nail, not hard enough to be brittle), and rub down the free surface on a piece of grit or rag-stone, until it is nearly thin enough, and carefully finish on the fine stone. When it is nearly thin it is as well to look at it every half-minute lest the process be carried too far. It has to be mounted in balsam, and it is desirable that the balsam should be so viscid as not to fill up the air and oil canals in the shell, otherwise their details will be obscured. Longitudinal sections may be made by the simple process of grinding, and sections in many cases should be made at different thicknesses. The really difficult "shells" to sectionize are those that are just too hard to be cut, and yet not hard enough to grind. This, however, occurs more frequently in seeds (as areca, the "stones" of dates, and strychnos) than in pericarps. Where it does occur the only plan is to soak the tissues in warm water for a considerable time, and cut as good sections as possible with a *cheap* razor. Mappin's shilling razors are about the best I have used. Their temper is sufficiently good to keep a sharp edge, but not so high as to cause the edge to "fly" against hard substances. An expensive, highly-tempered razor is the worst of all razors for sectionizing hard substances.

Seeds differ widely in their general structural details. We may roughly divide their tissues into those of the seed and the seed-coats.

The testa or seed-coat frequently consists of several distinct layers of cells, each of which has its characteristic features. Of these the outermost is usually the most interesting, and is frequently very beautifully marked. The following points respecting it should be ascertained. Is it membraneous, as in certain orchids? If so, does the membrane extend unequally over one or more sides, as in the seeds of certain climbers? As very beautiful seeds of this kind, may be named the seeds of the common British orchids, where the seed appears in a delicate membraneous bag, *Eccremocarpus*, sandwort (*Lepigonum marinum*), the anomalous seeds of *Sphænogyne speciosa*, where the seed appears to be a perfect plant, and in the exquisitely beautiful seeds of *Nemesia versicolor*, which seem to be dressed with delicate lace ruffles. Instead of being membraneous, this outer seed-coat may be tough and roughened by various protuberances arranged in more or less complex and beautiful patterns. Amongst seeds in which these obtain, I may name those of caryophyllaceous plants generally. The roughening may take the form of waved ridges (toadflax and snapdragon), or finer ridges, as in a very large number of seeds, or the surface may be reticulated more or less distinctly, as in the seeds of poppy and many other plants. Or, and this is a feature of very considerable importance, the outer coat may be furnished with hairs, as in a species of *Alyssum*, in *Ægle*, and a few others. The inner layers of the testa consist of very variously shaped cells, and will be described as they occur in the seeds that come under my notice in these articles.

Coriandri Fructus.—We may here neglect the structure of the chaff or husk-like seed vessel, and confine ourselves to the structure of the *mericarps* within it. These are of course of the great umbelliferous type, but present strong points of individuality. We notice first on superficial examination that each mericarp has *five* depressed ridges, which

* I should be glad to receive fresh specimens for this purpose. They may be addressed to me at 8, Hawthorne Place, New Wortley, Leeds. My object is to get leaves from as many localities as possible. Two or three leaves from each will fully suffice.

are more or less wavy, and *four* other ridges prominent and nearly straight. There are no *vittæ* except two small ones in each mericarp near the commissures. The outer integument of the seed consists of long, narrow, semi-ligneous fibres, disposed in a very irregular and interlaced manner. Within this is a loose layer of parenchymatous tissue, and within this the seed with its contents of oil and protein stuffs. These cells are of varied character. Near the exterior of the seeds they are compressed and angular. In the interior they are much larger, less angular, but still by no means spherical, and have well thickened walls presenting a very definite outline.

NEUTRAL HYDROBROMATE OF QUININE.*

BY M. BOILLE.

Two years since the author brought under the notice of the French Academy of Medicine an acid hydrobromate of quinine. Further investigation of its properties has led him to the preparation of the neutral hydrobromate, which he considers to be far superior to the official quinine sulphate, both as to solubility in water and richness in quinine. The neutral hydrobromate is prepared by double decomposition of bromide of barium and neutral sulphate of quinine, and is thus easily obtained pure and free from chloride; the great solubility of bromide of barium in alcohol facilitating the removal of any chloride, which is insoluble. The two salts are dissolved separately in alcohol, and the solutions filtered. The neutral sulphate of quinine solution is gradually added in slight excess to the bromide of barium solution, until a precipitate ceases to form. The solutions, diluted with water, are distilled to recover the alcohol, afterwards filtered, to separate the sulphate of quinine which has been precipitated by the water, and then concentrated sufficiently to induce rapid crystallization. The addition of water is indispensable for the concentration and crystallization; the hydrobromate, being soluble in alcohol in all proportions, re-dissolves as the alcoholic liquor is concentrated.

Neutral hydrobromate of quinine is also obtained easily by dissolving hydrate of quinine in weak hydrobromic acid. Upon cooling the salt forms beautiful nacreous crystals; re-dissolved several times in water, it crystallizes in the basic state.

Neutral hydrobromate of quinine has for its formula:—

$$C_{20}H_{24}N_2O_2,HBr,H_2O.$$

	Experiment.	Theory.
Water	4·80	4·25
Bromine	18·26	18·91
Quinine	75·20	76·59

The formula for acid hydrobromate of quinine is:—

$$C_{20}H_{24}N_2O_2,\ 2(HBr),\ 3H_2O.$$

	Theory.	Experiment.
Water	10·00	10·00
Bromine	24·62	28·84
Quinine	60·00	50·60

The crystallization of the acid hydrobromate of quinine in well-defined regular facets distinguishes it from the hydrochlorates, which crystallize silky in filaments. The former crystals do not become resinous in the presence of an excess of hydrobromic acid, and are prepared by dissolving quinine in an excess of hydrobromic acid; they are soluble in water and alcohol.

The solubility of neutral hydrobromate of quinine is stated by the author to be very remarkable, it being soluble in five times its weight of water. This solubility of the neutral salt he considers to be a property of high therapeutic value, as it should be better tolerated than the neutral sulphate, and more active, being more quickly absorbed. More soluble and more rich in quinine than the acid sulphate, he thinks it might re-place the latter advantageously in various liquid preparations, without causing the least irritation of the mucous membrane. Further, it combines the properties of bromine and the salts of quinine, whilst its easy absorption allows of its internal administration. On the whole M. Boille considers that its properties give it a great superiority over all other compounds of quinine.

AMERICAN EUPATORIA.*

BY DR. J. M. BIGELOW.

The genus Eupatorium in the United States comprises about thirty-two species. Three have been found exclusively in the eastern States, five in the southern States, and eleven in the Far West. Four species have been found common in the three grand divisions of the States, and nine are common to the eastern and southern States. Of those known to possess medicinal or toxicological properties, one (*E. sessilifolium*) is exclusively eastern, one (*E. incarnatum*) is exclusively southern, four (*E. perfoliatum, rotundifolium, teucrifolium,* and *aromaticum*) are common to the eastern and southern States, while two (*E. purpureum* and *ageratoides*) are common to the whole United States.

Eupatorium perfoliatum is officinal. Its history and properties are well described in Wood and Bache's *United States Dispensatory*. *Eupatorium teucrifolium* and *sessilifolium* possess similar properties, but appear to be milder in their operation than *Eupatorium perfoliatum*. The root of *Eupatorium purpureum* has bitter, aromatic, and astringent properties, and enjoys the local reputation of being an excellent diuretic, besides its tonic properties.

Burnett, in his 'Outlines of Botany,' mentions that *Eupatorium rotundifolium* is useful in consumption. It grows in dry soil near the sea-coast, from Rhode Island to Louisiana.

Eupatorium incarnatum and *E. aromaticum* contain an aromatic principle, similar to, if not identical with, coumarin, first obtained by Guibourt from *Coumarouna odorata*, Aub. (*Dipterix odorata*, Schub.), or Tonka bean. This principle, or one very similar, seems to pervade many plants, such as *Melilotus officinalis* and *M. cerulea*, *Asperula odorata*, *Trifolium melilotus*, *Anthoxanthum odoratum*, *Liatris odoratissima*, and probably many others. It is, without doubt, this principle which gives fragrance to *Eupatorium incarnatum*, *E. purpureum*, *E. aromaticum*, *E. odoratum*, etc. *Liatris* is a genus of composites, very closely allied to *Eupatorium*, and all species with aromatic fragrance and tuberous roots have long been known to possess active diuretic properties.

Professor Lindley, as long ago as 1848, mentioned the fact that bloody urine from inward contusions had been cured by coumarin, obtained either from the flowers of melilotus or the Tonka bean. This principle, besides being diuretic, is decidedly antispasmodic, and has been used by Dr. Cooper, of Philadelphia, in cases of pertussis.

There is a large class of troublesome diseases connected with inflammation and irritability of the bladder, in which the coumarin obtained from these plants—reasoning from analogy and the little experience we have already had of this substance—might be expected to produce decidedly beneficial results. Dr. Cooper gave to children of five years five to eight grains in a dose, prepared in the form of a fluid extract, with the happiest soothing effect upon the nervous system, which renders it worthy of a more extended trial.

Professor Wood ('United States Dispensatory,' p. 389, 13th ed.), with regard to the peculiar bitter principle of

* *Detroit Review of Medicine*, and *London Medical Record*.

the *Eupatorium perfoliatum*, remarks that, when the peculiar principle is isolated and satisfactorily determined, the name eupatorin will be proper; but he does not seem to remember that there are other species of *Eupatoria*, possessing other and very different properties, and that some of them may have a peculiar principle isolated and satisfactorily determined before the *E. perfoliatum*, and will then be entitled to priority in the name. Under these circumstances, it would be manifestly improper to apply it to the peculiar principle of *Eupatorium perfoliatum*. Already we see eupatorin (*perfoliatum*) and eupatorin (*purpureum*) advertised; but as yet neither of them is entitled to the name, as both are only concentrations of the several proximate principles, and not one peculiar to either of them. Eclecticism has a great penchant for the application and appropriation of scientific names; and among a large number of absurdities, we see *cerasin* and *prunin* advertised, which, if true alkaloids, as their names scientifically indicate, would be one and the same thing.

Eupatorium ageratoides, known popularly in some regions as white snake-root, is used by the eclectic physicians of Ohio as an antispasmodic, diuretic, and diaphoretic. In cases of nervous disease it is given in drachm doses, in the form of infusion.

But the greatest interest centred in this plant results from its having been suspected of being the cause of trembles in cattle and milk sickness, a severe and sometimes fatal disease of very local extension, making its appearance in the early settlement of isolated regions in the south-western portion of Ohio. It pervaded also portions of Indiana, Illinois, Kentucky, and Tennessee. Like the old-fashioned tertian ague, it has disappeared entirely upon the clearing up and cultivation of the land, which also destroyed the abundant prevalence of the weed. The late Wm. S. Sullivant, a distinguished botanist of Ohio, writing upon this subject in 1840, says that "this weed, hitherto considered harmless, has lately become the suspected cause of the fatal disease among cattle, commonly called the 'trembles.' The disease prevails in many localities in the western States, and is always accompanied by another equally fatal to the human species, known by the name of 'milk sickness.' It is generally believed they are both produced by the same cause originally, whatever that may be. A prevailing opinion is that some vegetable produces it. The poison-ivy (*Rhus toxicodendron*) has been strongly suspected by many, among them the late Dr. Drake, of Cincinnati. Mr. John Rowe, of Fayette County, Ohio, asserts that he has been successful in investigating this obscure subject. It was with the *Eupatorium ageratoides* that experiments on some cattle were made by him, in the presence of highly respectable witnesses. The disease was produced, and the cattle died from it. An account of the experiments, together with the certificates of the witnesses, was published in the *Ohio State Journal* of 1840. The details were not given as particularly as could be wished."

Mr. Sullivant was careful to ascertain that this was the plant used in those experiments, and also examined and identified specimens procured by Mr. T. Roberts, who was well acquainted with all the circumstances. He was assured also by Dr. Drake, of Cincinnati, to whom Mr. Rowe sent specimens, that it was the *Eupatorium ageratoides*. A difficult point to settle in this case is, that this plant, and likewise the poison-ivy, are very abundant in many places where these diseases are not, and never have been known. Mr. Sullivant was better acquainted with the geographical botany of the west than any other individual; and, never having seen or heard of any plant peculiar to such infected localities, he therefore concludes that the origin of the disease will not be traced to any particular plant, and especially the plant in question, as it is found growing in the east, west, north, and south.

Although not directly related to our present subject, it may not be uninteresting to refer to a South American plant of this genus—*Eupatorium glutinosum*. Professor Lindley remarks that the famous vulnerary, Matico, said to be derived from *Artanthe elongata*, a piperaceous plant, is really, according to Mr. Hartweg, the *Eupatorium glutinosum*. The following is the memorandum of Mr. Hartweg addressed to Professor Lindley on the subject: "Matico is the vernacular name applied by the inhabitants of Quito to *Eupatorium glutinosum*, or the 'chessalonga' in the Quichua language. It forms a shrub three to five feet high, and is common in the higher parts of the Quitinian Andes, where its properties were discovered some years back by a soldier called Mateo, better known under his nickname Matico (Little Matthew), who, when wounded in action, applied accidentally the leaves of some shrub to his wound, which had the immediate effect to stop the bleeding. This shrub happened to be the chessalonga, which has since been called, in honour of the discoverer, Matico. That it is the true Matico of the inhabitants of Quito and Riobamba I have not the slightest doubt; both the leaves and specimens have been gathered by myself, and, upon comparing the latter with Kunth's description, I found them to agree exactly with his *Eupatorium glutinosum*." Mr. Hartweg was a botanical explorer of considerable distinction, having collected many rare plants in California.

The 'United States Dispensatory' only refers to the Peruvian Matico (*Artanthe elongata*); but if the two should appear in market, as is not unlikely, it is important that the discriminating prescriber should know how to distinguish them.

Besides the Eupatoria above enumerated, we have eleven or twelve western species, of whose properties little or nothing is known. One among them, *Eupatorium Berlandieri*, common all over Texas, New Mexico, and extending into eastern Mexico, Dr. Gray says, is aromatic, and nearly allied to *Eupatorium aromaticum;* so that, if further known, some might be found worthy of a place in the materia medica.

BURNLEY CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual dinner of the above Society was held on Thursday evening the 1st inst., at Rawlinson's Hotel, Burnley. The Ex-President (Mr. Thomas) occupied the chair. After the usual loyal toasts, Mr. Fletcher proposed the "Success of the Burnley Chemists and Druggists' Association." He said he was glad to state that the Society had made progress during the past twelve months, and he hoped the time would soon come when the disadvantages which it had had to contend against would receive attention from the trade at large, and would be entirely removed.

The President (Mr. Crawshaw), in responding to the toast on behalf of the Society, spoke of the contrast between the past good old days and the present condition of pharmacy. He referred to the great advancement of education and the passing of the Pharmacy Act of 1868, which, he said, had, and would, improve the condition of each one connected with the trade. He pressed upon the members of the Society to work harmoniously together, casting aside the selfish and prejudiced feelings which tended to hinder the progress of societies, and hoped that the chemists in the surrounding districts would unite with the Society, as by so doing they would not only benefit themselves, but the trade in general.

Mr. Hitchin, in proposing a toast to the visitors, said he was sorry to see so few present from the neighbouring towns. He hoped each one would see the advantage of joining the Association, and that as each year rolled on they might be able to report increasing power, position, and brotherly feeling.

Mr. Hay, of Nelson, in responding for the visitors, said it afforded them great pleasure to be present, and they would be glad to join the Society in hopes of maintaining higher prices and shorter hours.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 17, 1874.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL NEOPHYTES AND THE PROVINCIAL ASSOCIATIONS.

BEARING in mind the old adage, "*Quot homines tot sententiæ*," we do not expect that the opinions uttered in these editorial columns will always meet with universal acceptance. In fact, in some instances the object sought may be best attained when such opinions are challenged and disputed; for active thought of any kind is preferable to apathetic indifference, as being more likely to remove the fogs of prejudice and inexperience which more or less cloud the perception of the clearest-sighted among us. When, therefore, the recent articles on the subject of the examinations were inserted it was with the full expectation that they would be the cause of protests, and the expectation has not been unrealized. One writer denies that the apprentice or assistant, as a rule, has the time to allow him to "bend his own glass tubes, make his own thermometer, and fit up his own apparatus." Another condemns the examiners and all their works, and answers the questions,—"Could an examining body have asked less? are they asking for the wrong things? are they seeking to catch me with their guile, or setting traps, or placing stumbling-blocks before the unwary?—with a decided affirmative. Whilst others lament that the stringency of the examinations has outstripped their opportunities and ability to obtain the necessary education.

Granting that hours of business are long, we demur to that fact being put forward as sufficient evidence of the impracticability of study. There is no royal or easy road to pharmaceutical knowledge; therefore, whilst earnestly urging employers to render the way as easy as possible, it is well to remind intending travellers that they must be prepared to suffer personal inconvenience, and not to expect the sacrifice to be all on one side. Admitting, too, that examiners are apt to put questions not exactly in accord with the wishes of the examinee, the correctness of the imputation angrily thrown out is not a necessary sequence, and we do not care to discuss it. We think it would be more profitable to consider the objection that the stringency of the examinations is not in accord with the opportunities of those who have to undergo them, as well as the question whether the means which do exist are so used as to encourage the creation of others.

What are the facts of the case? Scattered throughout the country are various pharmaceutical societies, many of which have in connection with them classes or some other organized facilities for supplying to the pharmaceutical student that scientific knowledge which is to help him in systematizing the practical information obtained in the performance of his ordinary duties, and fit him for a certificate of proficiency as a chemist and druggist. If only a fair measure of success attended these organizations, there is little doubt but that they would be multiplied. Nevertheless, the number is stationary, and promises to grow less. Why? The old proverb ran, "*Ubi mel, ibi apes.*" But in many places these educational blossoms are almost deserted by bees, and but little of the honey is ever hived. In other words, rooms and teachers are provided, but pupils are not forthcoming. Our columns this week testify to the fact that it has been proposed to wind up one Association; not because it lacked teachers, funds, or accommodation, but because those for whom the classes were provided failed to avail themselves of them. In another instance "the effort to sustain a Pharmacopœia class was not successful.' The officials of a third Association also lament that all their efforts to promote pharmaceutical education have been "in vain." In fact, the conditions that might have been expected to obtain are reversed, and, instead of a rush of eager applicants for the boon, those who provided it have had to urge its acceptance upon individuals, who have replied with an indifferent refusal.

This result is certainly ominous of trouble in the future; but the greatest sufferers by far will be those whose short-sighted *laissez faire* leads them to neglect the assistance which has been so generously offered to them. In their own interest, and in the interest of others who do not yet enjoy opportunities like those neglected by them, we would urge them to "turn over a new leaf," and let the new session be prolific of encouragement to such as have been sparing neither in their time nor money in the cause of pharmaceutical education. This much is certain: all who aspire to enter within the pale of pharmacy must work at some time or other, and they will then need assistance, which may not always be within their reach. It would be foolish to expect any lowering of the standard; for it cannot be expected that men who have already attained a position will baulk their hopes of a brilliant future for English pharmacy out of consideration for others who have thus early shown the white feather.

CINCHONA CULTIVATION IN ST. HELENA.

ABOUT eighteen months since, MR. OSWALD READE described in this Journal (vol. iii., p. 903) what he saw during a visit to the cinchona plantations in the Island of St. Helena. Notwithstanding that the experiment had been described to him as a failure, MR. READE arrived at the conclusion that the cultivation of the red cinchona in the island would be a success were it well looked after. It is, therefore, satisfactory to learn that the abandoned plantations have recently been the subject of correspondence between the authorities and Dr. HOOKER, and the *Gardeners' Chronicle* quotes the following from a St. Helena paper:—

"We understand that measures are being adopted in earnest to increase the plantations, and advantage taken of the present favourable season to strike cuttings and plant out all available young plants. We are also happy to hear that the plantation is not to be, as before, strictly confined to one locality, but that the trees are to be tried in various situations, and that no difficulty will be made in allowing private individuals to procure cuttings or plants whenever they can be spared. A good quantity of the bark has been collected, to be forwarded to England for examination and analysis. So far as appearance and taste go, this is precisely similar to the Peruvian bark of commerce. . . . . It is very satisfactory to find that our present governor is alive to the importance of this cinchona business, which we may now fairly consider to have got beyond the stage of experiment, since it appears there are now on the spot, neglected for three years, some three hundred trees, all in full vigour of leaf and blossom, from six to twelve feet high, and with stems three or four inches in diameter, and bark a quarter of an inch thick. Let us hope that Governor JANISCH will continue vigorously to propagate these valuable trees on all the Government lands which are found suitable. Then, when his term of office shall expire, he may have the satisfaction of knowing that he has earned the same title to public gratitude as is said to be due to the man who makes two blades of grass to grow where only one grew before. And as it may be hoped that Mr. JANISCH'S government may endure for a considerable period, it is most important that he should have taken up so warmly this question of cinchona trees, it being a well-known fact that every new governor takes up a new hobby, and no one was ever yet known to carry out the plans of his predecessor. The only exception is our present governor, who is now carrying out the plan of clothing the central ridge of our island with the trees that yield quinine, after the plans of his predecessor, Sir CHARLES ELLIOTT. But even this exception is qualified by the fact that Sir CHARLES'S immediate successor reversed all his arrangements, and allowed the plantations to go to waste, and, besides, Mr. JANISCH was Sir CHARLES'S Colonial Secretary."

FEMALE DISPENSERS.

THE *Lancet* states that the Woolwich Board of Guardians, having advertised widely for a dispenser, received only one application for the post, and that from a lady. The Guardians, however, considered her to be ineligible on account of her sex.

ARTIFICIAL VANILLIN.

AT a recent meeting of the French Academy of Sciences, Dr. A. W. HOFMANN announced that his two pupils, Messrs. TIEMANN and HAARMANN, who discovered vanillin in the products of a reaction commencing with the juice of the pine (see vol. iv., p. 996) have established a flourishing industry based upon that discovery. The juice of a tree of medium size yields a quantity of vanillin of the value of one hundred francs, and it is found that the wood is not injured by the extraction of the juice.

MR. ROBERT S. G. PATON, Ph.D., F.C.S., has been appointed Public Analyst for the Borough of Stirling.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

ANNUAL MEETING.

The annual meeting of the 25th session of the above Association was held at the Royal Institution, Liverpool, on September 24th, 1874. The chair was occupied by the President, Dr. Charles Symes.

Several donations to the library were announced, and Mr. Edward Pritchard was elected an associate.

The Hon. Sec., Mr. Jas. T. Armstrong, then read the annual report :—

"The report of your Council for the past year completes the history of the operations of this Association for the first quarter of a century of its existence, and your Council feel they are not saying too much when they state that the character which it has established during that period will enable it to bear favourable comparison with any society of a similar nature and with a kindred aim. They feel that while it has not been free from fluctuations it has had, on the whole, a successful career, and they trust that its future may be even more prosperous than its past.

"During the past session 13 members and 3 associates have been admitted, and this makes the members at present on the books 155, comprising—honorary members, 14 ; members, 125 ; associates, 16.

"The attendance at the ordinary general meetings has been good, and at a special meeting at which ladies were present, and Mr. Edward Davies, F.C.S., delivered a lecture, there was a numerous attendance.

"The work that has been done at the ordinary general meetings may be classed under four heads, viz : scientific chemistry, pharmaceutical chemistry, discussion on the working of the Adulteration Act, and one on the best means of promoting pharmaceutical education. The number and character of the papers read show that this Association is equal in this respect to any association of a similar nature.

"Much time has been devoted, both in Council and at the ordinary meetings, to discussions on the working of the Adulteration Act, resulting in the decision not to take any public action in the matter.

"In compliance with a requisition signed by twenty members, an extraordinary general meeting was held on March 26th, to consider some alterations in the rules as proposed by Dr. Cook and Mr. Hallawell, but after a long discussion nothing definite was settled, it being understood that the subject would be again brought forward at the annual meeting.

"Your Council feel that they have done all in their power to promote pharmaceutical education and the welfare of the students. Not only did they cause a special meeting to be held, at which students were invited to come forward and say what they required in this matter, but also a meeting of the Association was purposely given to them, at which Dr. Symes read a paper on "Study," and Mr. Jas. T. Armstrong, F.C.S., read another on "Pharmaceutical Education." Your Council greatly regret that all this has been in vain.

"There has been during the past year a change of the librarian, and your Council feel with good results, for the books are kept and delivered in a much better manner than they have been for some years, and things are in every way differently managed.

"The museum has received several additions in the form of donations, amongst which might be named a collection of specimens illustrating additions to the British Pharmacopœia, from Messrs. Evans, Sons, and Co., and some botanic specimens from the Exhibition, 1862, which have only now come to hand; very few of these, however, were available.

"Mr. Edward Davies, F.C.S., has during the past session conducted the chemistry class as usual, and with very fair success.

"The following gentlemen were appointed during the past year to attend the meetings of the Pharmaceutical Conference in London: Messrs. Sumner, Shaw, and Mason.

"The following gentlemen retire in rotation from the Council, but are eligible for re-election: Messrs. Abraham, Shaw, Sumner, and Redford.

"The report of the finance of this Association as presented by your treasurer shows a deficit of £5 2*s.* 9*d.*"

The Treasurer then read the following financial statement:—

The Liverpool Chemists' Association in Account with John Shaw, Treasurer.

Session 1873-4.

Cash Received.

Joseph Hallawell, } Auditors.
Thos. F. Abraham, }

September 24, 1874.

The usual annual business having been gone through, the President closed the meeting by saying that he hoped the next session might be a very prosperous one.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

The annual general meeting of the above Association was held September 25th, Mr. E. Nuthall, President, in the chair. In opening the meeting the President said, there was little occasion to detain them with his remarks, as the position of the Society would be shown by the reports which would be read to them, and the questions they would have to consider had been laid before them in the circular convening the meeting. In the face of the fact of a circulation of about 70 notices resulting in so small an attendance, at a meeting of such primary importance, he thought there could be no doubt as to the advisability of bringing the Association to an end. After reading letters from Messrs. Caley, Corder, and Thompson, honorary members, expressive of regret at their unavoidable absence, and still more at the contemplated dissolution of the Society, he explained that the Treasurer would be unable to present a duly audited balance-sheet, owing to this meeting being held before the termination of their financial year.

The Treasurer, Mr. W. J. G. Butler, stated that at the end of the present month there would be a deficit of 12*s.* 7*d.*, if they excluded the grants earned by the science classes. From this source £16 would accrue to the Society.

Secretary's Report.

"The preceding year has been the least satisfactory of any. The Council recognized during the previous years (1872-73) the necessity for some course which should invigorate the proceedings of the Association, and with this view obtained permission from the members at their last annual meeting to conduct classes in chemistry and botany in connection with the Science and Art Department. These two classes form the only satisfactory features of last session. At the outset, an influential Committee was got together by the President, consisting of the Rev. Hinds Howell, Dr. Beverley, and Messrs. T. Pinder, C. Williams, and F. Sutton, but owing to the short time intervening between this formation and the commencement of the classes, only four outsiders were induced to attend, whilst the attendance of members numbered 11. Out of these students an average of 10 attended the chemical, and 8 the botanical class, and 7 presented themselves in the former, and 3 in the latter subject at the May examination, all of whom passed viz.: 7, 1st class; 3, 2nd; 5 of chemistry class also passed in laboratory practice. This success results in the Science and Art Committee claiming £16 from the department, which sum, through the kindness of the class teachers and the Committee, is entirely at the disposal of this Association. The Council would here recommend that this sum be thus disposed of, viz., a portion to be devoted to the purchase of books, to be presented to the class teachers as a slight recognition of their services, and that, in the event of the Association being dissolved, the balance, after paying all claims upon the Association, be handed over to the Science and Art Committee for the carrying on of such classes. And here the Council desire to express their deep sense of the loss that has befallen the Association, in the death of Mr. G. Tooke, who, from being one of the most diligent pupils at the classes, had risen to be an exceedingly energetic teacher of chemistry. The class, which had at the outset of the session been conducted by Mr. Tooke, was ably carried on by Mr. Woolnough, who had kindly volunteered to fill the gap, but he was now unfortunately lost to the Association, through leaving Norwich. Mr. W. Piper conducted the botany, Mr. Nuthall assisting both the teachers.

"The remaining features of the past year require very brief notice. Trade classes in chemistry, materia medica, and pharmacy, conducted severally by Messrs. Nuthall, Caley, and Butler, were discontinued on account of the apathy of the members.

"During the past year two additions have been made to the library, but there have been no further funds available for the purpose. The circulation of books during the winter months was fairly satisfactory, but during the summer there has been little or no demand.

"The number of members and honorary members on the books of the Society during the four years of its existence has been:—

	70-71	71-72	72-73	73-74
Members	42	36	25	20
Honorary members	19	21	13	11"

In the discussion which followed it was stated that there were about fifty assistants and apprentices in the city, the greater portion of whom had not yet passed the Minor examination, and consequently there should be fair field for the work of the association.

Upon considering the financial prospects for another year, it was shown that no fear need be entertained as to the ability of the Association to pay its way. It was therefore resolved, on the recommendation of Mr. Robinson (hon. member), that the meeting be adjourned until Wednesday, September 30th, and, in the meanwhile, all connected with the trade in the city should be personally canvassed, not only as to their willingness to join the Society, but also as to their attendance at the classes. This task was undertaken by Mr. Robinson and the President. After the usual vote of thanks to the Chairman, the meeting adjourned.

The adjourned meeting was held September 30th, when there was a marked increase in the attendance. After reading a letter from Mr. Cubitt (hon. member), expressive of his desire to assist in the reconstruction of the Society, the President briefly reviewed the proceedings of the last meeting. He then reported that the personal canvass undertaken by Mr. Robinson and himself had been very satisfactory. From employers, with one sole exception, they had heard nothing but wishes for the future success of the Society. They had not met with quite so much encouragement from the apprentices, eleven of whom had declined to give a decided answer as to whether they would join the Society; but of these eleven seven had not yet passed their Preliminary, so, perhaps, could not be expected to be so ready to enrol themselves as students. Still they had already the promise of nine new active and four honorary members, and there were yet several to be canvassed. Under these circumstances they would have amongst them about thirteen whom they might depend upon as students.

The question, then, for decision was whether that number of students was sufficiently large to justify the continuance of the Association. There was no question as to funds; they had a balance in hand of £11, and a further income of £30 from subscriptions and hire of rooms to science classes. If the Association should be continued, the Council would be able to offer a more attractive programme than at any previous period; indeed, the retiring Council had drawn up a complete scheme of classes, etc., which they would recommend their successors to adopt. He might mention that chemistry would be made a very important item, and in the face of so large an income they were prepared to fit up some benches for practical work on the part of students. To conduct courses of practical chemistry, including all the testing required for the Major and Minor examinations, they had received promises of assistance from a doctor of science, and a gentleman recently connected with a London laboratory. Further, it was proposed to invite some London professors to give occasional lectures.

Mr. Corder (honorary member) thought that under the conditions laid before them by the President there could be no doubt as to the advisability of carrying on the Society, as he felt sure that the want of such an Association would be more than ever felt now that the stringency of the examinations was so much increased. Speaking from experience as an examiner, he must say that he found that candidates from the country, especially from such places as possessed similar Associations to their own, were much better prepared than those who had depended upon a few months' "polish up" at a London school.

Mr. Caley (honorary member) said it was frequently to be noticed that many failed to value a thing until it was lost to them. He hoped that this would not be the case with regard to this Association. For his part he thought their future was clear, and exhorted members to enter into study with more heart, assuring them they would find great pleasure in the acquisition of knowledge, quite independent of passing any examination.

Mr. Cassey moved, and Mr. Robinson seconded, that the Association be continued.

In supporting this proposition, Mr. Butler noticed that certain hints had been thrown out as to whether the Society did sufficient for its members. He thought such opinions could only obtain with those who confounded the work of the teacher with that of the student. All students should bear in mind that, however able and energetic a teacher might be, attendance at the classes would be simply thrown away did they not supplement their class-work by home study.

After a little further discussion Mr. Cassey's proposition was carried unanimously. In reply to a suggestion from Mr. Corder, that honorary members be associated with members in the management of the Society, the President stated that in order to do so it would be necessary entirely to reconstruct the Association, which must then become the Norwich Chemists' and not the Norwich Assistants' Association. Still, he should be glad to hear the advisability of such a step discussed, and should wish to pursue any course that would lead to the strengthening of the Society.

Mr. Corder said he hoped he should not be misunderstood. He had no desire to see the Association cease to exist as an assistants' society, but had been desirous of strengthening the Council's hands as much as possible. A desultory conversation on this point resulted in its being resolved, on the motion of Mr. W. Piper, seconded by Mr. W. H. Symons, that the Association be carried on in future as a Chemists' Association.

After several divisions, it was further resolved that the Council be enlarged to eleven, of whom four should be employers and seven employed.

Upon the motion of Mr. Fox, seconded by Mr. T. C. Pitts, it was then resolved to adjourn the meeting until that day week, for the purpose of acquainting those members of the trade not present of the change in the constitution of the Society.

At the adjourned meeting the rules of the Association were revised, so as to meet the requirements of the altered *status* of the Society, and the following gentlemen elected to serve on the Council for the ensuing year:—Mr. Edwin Nuthall, president; Mr. O. Corder, vice-president; Mr. W. J. Gooch Bush, treasurer; Mr. G. C. Fox, secretary; Mr. W. H. Cooke, Mr. J. Cossey, Mr. W. G. Piper, Mr. J. Robinson, Mr. W. H. Symons, Mr. J. Watson, Mr. T. C. Pitts.

Since this meeting a programme for the winter classes and the subjoined statement of accounts for 1873-4 have been circulated amongst the members:—

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The inaugural meeting of the twentieth session of this Society was held in the West Hall, Anderson's University, on the evening of Wednesday, the 30th of September. The President, Mr. John Currie, sen., pharmaceutical chemist, occupied the chair.

The first instalment of books for the library were exhibited to the members, which included 'Watts' Dictionary,' 5 volumes and supplement; 'Bentley's Botany;' 'Fownes's Chemistry;' 'Proctor's Pharmacy;' 'Thorpe's Quantitative Analysis;' 'Sutton's Volumetrical Analysis;' 'Royle's Materia Medica,' etc.

Several new members were proposed and introduced to the meeting.

The President afterwards delivered the following opening address:—

"Gentlemen, as the winter session of the Chemists and Druggists' Association is about to commence, it is customary for the President to deliver an address on some useful object bearing upon the interests of the trade. The topic I have chosen to speak upon is the present aspect of the trade, with reference not so much to employers, but chiefly with regard to assistants and apprentices already in the business, or to those who have some intention of joining it. But, first of all, I may be permitted to take a review of the proceedings of the Association during last session. We found then that the membership, and the revenue from that source, were much the same as that of the previous year. The attendance at the ordinary meetings was good, and a general interest in the welfare of the Association was manifested. The assistants' meetings were also well attended; several essays were read on different subjects by members, and followed by interesting and profitable discussions. At intervals during the winter the Association was favoured with lectures of a scientific kind by several medical friends. The first of the series was delivered by Professor A. Wood Smith (now of Anderson's University), on the Blood, its constituents, circulation, and the functions it performs in sustaining life. The second lecture was given by Dr. Nairne, on the Brain and nervous systems. The third lecture was delivered by Professor J. E. Thorpe, then of the Andersonian University, on the discoveries of the late Dr. Graham, of the Mint, showing the constitution of the atmosphere at various elevations. The fourth and last of the series was delivered by Dr. Fergus on the very important subject of pure air and water. The Doctor's remarks bore chiefly upon the contamination of water with organic matter, as a fruitful source of disease, such as gastric fever, diphtheria, etc.

"At some of the meetings it was suggested that a library should be formed for the benefit of the Association. I need scarcely say that this was heartily responded to, and a committee was appointed to carry it into effect. The City and suburbs were accordingly canvassed, with the gratifying result that a sum of nearly £40 was suscribed. It was felt that a microscope was almost as necessary for conducting investigations in the sphere of botany, chemistry, etc., and the Committee was authorized to procure one. It was, however, found unnecessary to buy one, Messrs. Evans and Co., of Liverpool, having generously presented the Association with an instrument of excellent quality, and sufficiently powerful for the purpose.

"Reference should be made to the Price List published by authority of the committee which the Association appointed for that purpose about two years ago, and which has been revised twice since. From the testimony of the trade, it has worked well, has met with general approval, and been found very useful in establishing a somewhat higher tariff for medicines in ordinary demand, and specially in the dispensing department, thereby securing better remuneration for the pharmacist. It is to be hoped that there will be a strict adherence to the Price List, and that in a short time there will be uniformity of prices throughout the kingdom.

"So much for the past session; let us now consider what aspect the trade assumes at present, and what may be its probable future. For some time back employers have had difficulty in procuring suitable assistants, arising, no doubt, to a considerable extent, from the fact that a superior education is now required, and certain examinations have to be passed before they can commence business as chemists or druggists. The effect has been, that not a few good assistants have left the business altogether, and others have been deterred from joining it. Then there has been of late a tide of commercial prosperity which has risen so high that many have been induced to join some more lucrative, although, it may be, less honourable, calling than our own. This is certainly to be regretted, but not to be wondered at. When this tide has ebbed somewhat, however, and things assume their ordinary course, and when the higher position the trade is likely to take is duly considered then the prospective advantages of the business will not fail to recommend themselves.

"In the meantime employers must submit patiently to a little inconvenience, and, at the same time, assistants and apprentices, not discouraged by the difficulties which lie in their path, must address themselves to meet and successfully surmount them, and that just in the usual way of attendance on the prescribed course of regular and systematic instruction. The Preliminary examination should be got over without delay; then classes of botany, chemistry, and materia medica should be attended, either at the University or the Andersonian; any other method of getting up these subjects will only end in waste of time, probable failure, and expense. I would remark that while we are glad to see so many young men entering as candidates for the various examinations here and elsewhere, we cannot fail to be painfully struck with the large number of failures—amounting to upwards of 40 per cent., or nearly a half. I hope that this state of matters will soon be obviated, and that the young men of Glasgow and the West of Scotland will take a high position in these examinations, and that not a few will pass with honours. Let me remind you of the facilities you now have of obtaining information. You have a library which promises to be large and well stocked with books on every subject which you require to study. You have a microscope with which to conduct your various investigations; and to these let me add the advantage you enjoy of easy access to the Andersonian or Glasgow University, a privilege that very few country assistants have. I would strongly recommend you to avail yourselves of your opportunities, and show your appreciation of them.

"Your Council have been devising means not only for assisting you in your studies, but also of providing for your recreation during the winter; they therefore expect a fuller attendance at the meetings, and also an increased membership. You will find that by frequently meeting together and exchanging opinions you will materially assist each other. A good deal has been said of late years to the prejudice and disparagement of the drug trade, as if the time had gone by to make much of it. I cannot sympathize with any such idea. I hold that our trade is a good one, if properly prosecuted. And by the legislative enactments obtained by the Pharmaceutical Society it now holds a higher position in the estimation of the medical faculty and the general public than it did. After the experience of many years, I will only say that if any well-educated man will engage in the trade, learn it thoroughly in its details, and pass the examinations required, provided he be steady, diligent, and attentive, and prudent in managing his business, although it may not be his lot to make a fortune, he will, under ordinarily favourable circumstances, make an honourable as well as a comfortable living."

Mr. Currie was frequently applauded in the course of his remarks, and at the close, after a few remarks from Mr. Kinninmont (one of the Board of Examiners), who refuted the idea that the new regulations would make the examinations more difficult to pass, a hearty vote of thanks was awarded to the President for his address.

A committee was afterwards appointed to arrange for classes for students and apprentices to be held throughout the winter months. It was also decided that the annual festival should take place on the 20th January next.

Mr. J. M. Fairlie (Secretary), as one of the delegates to the Pharmaceutical Conference meeting at London in August last, gave a brief report of the proceedings, drawing special attention to the more interesting of the papers read, and urged the members to enrol themselves as members of the Conference. He also stated that in all likelihood the Conference would meet in Glasgow in 1876, and he hoped the Association would look forward to giving the members of the Conference a hearty welcome on that occasion.

It was intimated that the next scientific meeting of the Association would be held on October 28th, when the

President of the North British branch of the Pharmaceutical Society would deliver a lecture on "Chromatic Phenomena of Crystallization," with illustrations, and that at the opening meeting of the assistants' section on 14th October, the President, Mr. J. C. Hunter, A.P.S., would deliver a lecture on the "History of the Microscope."

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

A meeting of the above Association was held at Birmingham, on Friday evening, October 2nd, the President, Mr. Thomas Barclay, in the chair. There was a good attendance of members and associates.

The Secretary (Mr. W. Jones), having read the minutes of the previous meeting, which were confirmed, gave a statement of the accounts which was accepted, after which the President introduced Mr. Dewson, of the Queen's Hospital, as a teacher of pharmacy, etc., and spoke very highly of his professional attainments and capabilities for imparting knowledge to students. It was resolved, in the interests of the Association, to secure the services of Mr. Dewson, who was warmly received by the meeting, to conduct classes in connection with the Association.. A committee was formed to make the necessary arrangements.

Mr. H. W. Jones, one of the deputation to the Pharmaceutical Conference, then read his report, in which he detailed the proceedings of the Conference; he also noticed the principal events which had occurred in the pharmaceutical world during the previous three months. Various prosecutions were discussed. It was shown that three out of the four prosecutions instituted against chemists, during the recess of the Association, had been dismissed,—the citrate of iron and quinine case on the explanation of Mr. Howard, whose firm supplied the article; the scammony case, on the certificate and evidence of Dr. Attfield; the arrowroot case, on the certificates of Dr. Redwood, Dr. Voelcker, Mr. Stoddart, and Messrs. Southall; a fine being inflicted only in the sulphate of quinine case, in which the alleged adulteration consisted of the addition of a salt of cinchonine. Mr. Jones exhibited Horsley's tubes for analysing milk, and showed, in the tubes, samples of pure and adulterated milk, with the variable amounts of butter-oil. A specimen of Liq. rhamni frangulæ was also exhibited. In illustration of remarks made in reference to "carnivorous plants," specimens of the round-leaved sundew (*Drosera rotundifolia*), and the pitcher plant (*Sarracenia purpurea*), were shown. A discussion followed the paper, in which the President, Messrs. Lucas, Churchill, Grieves, A. Southall, Homer, and others took part.

It was resolved to hold the usual annual soirée, and a committee was appointed to make the necessary arrangements. The affair promises to be, as usual, a brilliant success.

BRISTOL PHARMACEUTICAL ASSOCIATION.

At a meeting of the above Society. held on Monday, October 5, Mr. G. F. Schacht, F.C.S., was re-elected president; Mr. Charles Boorne, vice-president and treasurer; and Mr. John Pitman, honorary secretary.

The following gentlemen constitute the Council for the ensuing year:—Messrs. G. F. Schacht, R. W. Giles, W. W. Stoddart, C. Boorne, C. Townsend, J. Stroud, R. C. Cuff, E. Player, J. Taplin, J. Boucher, G. W. Isaac, and John Pitman.

The Council have issued a circular announcing that they have made arrangements by which they are enabled to offer to their fellow members and associates the following complete course of instruction in chemistry and botany for the session 1874-5:—

Chemistry.—A course of lectures by Mr. Coomber, F.C.S., on Inorganic Chemistry, every Tuesday, at 8 p.m., commencing October 20th. A course of lectures by Mr. Coomber, F.C.S., on Organic Chemistry, every Thursday, at 8 p.m., commencing October 22nd.

Botany.—A course of lectures by Mr. Leipner, on botany—elementary, systematic, and physiological—every Monday, at 8 p.m., commencing October 19th.

At the conclusion of the session, in May next, an examination will be held in each subject, at which every student is required to present himself. In connection with that examination the Council intend to offer a series of prizes, particulars of which will be shortly communicated.

Tickets for either of the two subjects—chemistry or botany—will be five shillings for members and associates, provided the holder complies with the condition of presenting himself for examination, and shall have attended not less than 20 lectures in each course, in accordance with the regulations of the classes; otherwise the fee will be ten shillings. Students are earnestly advised to abstain from entering for more courses than they can reasonably expect to follow up.

Tickets for the above lectures may be obtained of the following gentlemen:— Mr. Boorne, Union Street, Bristol; Mr. Stoddart, North Street, Bristol; Mr. Schacht, Clifton; Mr. Isaac, White Ladies Road, Bristol; Mr. Pitman, Redcliff Hill, Bristol, who will give any further information which may be desired.

A course of practical laboratory instruction will be conducted by Mr. Coomber, on Friday evenings, at the laboratory in Nelson Street. The fee (inclusive of apparatus and chemicals) will be £1 1*s*. per quarter. Tickets to be obtained of Mr. Coomber only.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The fifth general annual meeting of the members of the above Association was held on the 5th inst., for the purpose of electing the officers and committee for the ensuing year, when the secretary (Mr. Hedley) being called upon, read the following:—

Report.

"Your committee, in presenting this its fourth annual report, would congratulate you upon the continued existence of the Manchester Chemists' Assistants' Association; at the same time, it is a matter of deep regret to announce that the interest taken in it by the members has not been so great as such an institution demands.

"It feels assured that a little more energy on the part of the assistants would be productive of much good to themselves and to the Association, inasmuch as they would be brought into social intercourse with each other, a state of things very much to be desired amongst any body of men, and which they are sorry to say does not at present exist to any great extent amongst chemists and druggists.

"During the session there have been eight meetings held, at seven of which papers were read by members as follow:—On Opium, by Mr. W. Lane; Phosphorus, by Mr. Pidd; Mercury and its Salts, by Mr. Strickland; Leaves, by Mr. Roebuck; Light, by Mr. Hurst; Heat, by Mr. Slinger; The Progress of Pharmacy, by Mr. Davidson. At the eighth an instructive lecture, which will ever be remembered by those who had the pleasure of listening to it, was delivered by Mr. Siebold on "The Constitution of the Organic Bases," with reference also to organic analysis. Your committee regrets that the effort to sustain a Pharmacopœia class was not successful, and, in consequence, the class was discontinued.

"Your committee is happy to say that in a financial point of view the Association has not yet become insolvent, there being a balance in the hands of the treasurer. On retiring from office, your committee desires to express a wish that the Association may long continue to prosper, and be in the future what it has hitherto been—'an Association for improvement both in intercourse and instruction.'"

The report being unanimously adopted, the election of officers and committee was next proceeded with, resulting in the re-election of Mr. Lane as president and Mr. Booth as vice-president, Mr. Clegg as secretary and treasurer (vice Mr. Hedley, resigned), and the following gentlemen to serve on committee, viz.:—Messrs. Davidson, Hedley, Illsley, Kennerley, Roebuck, and Sanders.

The president then delivered his annual address, giving the history of the Association from its origin up to the present time, in the course of which he warmly eulogized the services rendered to the Association by Mr. Siebold (the mention of whose name was received by the members with applause), and concluded by urging upon the members the necessity of such an Association, and the advantages to be derived from it, and expressing a hope that the attendance at the meetings of the forthcoming session would be such as to ensure lively and animated discussion on the subjects brought forward.

A vote of thanks to the retiring officers and members of the committee concluded the business of the evening.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

(Concluded from p. 252.)

The second and third sitting of the twenty-second annual meeting of this Society was held in the Liederkranz Hall, Louisville, Ky., on the 9th September. The officers and committees for the ensuing year were then nominated. Among them were the following:—

President, Professor C. Lewis Diehl, Louisville; Vice-Presidents, Joseph Roberts, Baltimore, W. T. Wenzell, San Francisco, A. R. Bayley, Boston; Treasurer, C. A. Tufts, Dover; Permanent Secretary, Professor J. M. Maisch, Philadelphia; Reporter on Progress of Pharmacy, Professor C. Lewis Diehl, Louisville; Local Secretary, S. A. D. Sheppard, Boston; Executive Committee, George W. Kennedy, W. McIntyre, J. L. Lemberger, C. A. Heinitsh; Committee on Legislation, Professor John M. Maisch, F. L. A. Greve, R. B. Ferguson, George J. Luhn, A. G. F. Streit, S. S. Garrigues; Permanent Committee of the Pharmacopœia, Professor G. F. H. Markoe, Professor P. W. Bedford, A. B. Taylor, Professor J. Faris Moore, A. E. Ebert, W. H. Crawford, J. C. Wharton, Professor C. Lewis Diehl, Professor R. H. Stabler, Professor J. F. Judge, Professor W. T. Wenzell, Paul Balluff, William Saunders, C. A. Tufts, M.D., C. H. Dalrymple.

It was then resolved that the officers of the Association be empowered to enter into correspondence with any international body that may have been created for the purpose of effecting a unification of the plan upon which the different pharmacopœias have been constructed.

It was also resolved, that the executive committee, with the approval of the president and treasurer, be empowered to publish annually, with the proceedings, the likeness of one or more departed members, and that for the forthcoming volume, Professor William Procter, jun., be selected.

It was further resolved, that a committee of three be appointed by the president to report at the next meeting upon the possibility of the publication of a table of maximum doses, and to devise a plan by which physicians can distinctly indicate unusually large doses in their prescriptions.

The committee on the drug market presented their report, read by the chairman, Professor P. W. Bedford. In alluding to the imports of drugs, chemicals, dye stuffs, etc., it was stated that the total imports for the year ending June 30, 1873, were of

Dutiable drugs, etc.	12,202,344 dols.
Free ,, ,, ...	20,610,605 ,,
Total	32,812,949 ,,

The amount of duties paid on this was 4,441,853,853 dols., making a ratio of 36·4 per cent. on dutiable goods, or 13·5 per cent. on the total imports. Almost all crude drugs and articles from which manufactures are obtained are free of duty. As compared with other large imports it will be observed that the ratio of duty is favourable to the pharmaceutical vocation.

Statistics were furnished showing the drugs rejected at the Custom House in New York, and a large number of notes were read giving the supply, values, character, and fluctuations of the drug market of the year. The report of the committee upon sophistications and adulterations was then read on behalf of Charles Rice, chairman.

Professor Maisch read the report of the committee on legislation, of which he is chairman, and gave all the information which he had been able to collect during the year, relating to laws affecting pharmacy. He stated that in some of the southern States old laws affecting pharmacy had been exhumed, and attempts to enforce them had been made, to the discomfort of many in the business.

The committee on papers and queries now requested that replies to queries be called up. Of the fifty-two queries, twenty-five were responded to, seventeen were continued another year, and ten were dropped.

The treasurer's report gave the receipts and disbursements of the year, adding that quite a large number of persons had failed to meet their dues, and were likely to be dropped from the roll of membership. In all respects the financial affairs of the Association were satisfactory. The report was referred to an auditing committee, who subsequently reported that it corresponded with the vouchers, and warmly commended the treasurer for his care and neatness with his accounts.

Replies to queries and discussions occupied the balance of the sessions of this day.

The fourth and fifth sessions were held on Thursday. Mr. William Saunders offered a resolution, which was unanimously adopted, recognizing the great loss the Association had sustained in the loss of one of its founders, Professor William Procter, jun., of Philadelphia.

It was then decided that the next place of meeting should be Boston, and the time the 12th September, 1875.

Several propositions to amend the bye-laws were adopted; among them:—

To increase the salary of the permanent secretary to 600 dols. per annum;

To increase the salary of the treasurer to 400 dols. per annum;

To fix the salary of the reporter on the progress of pharmacy for the ensuing year at 500 dols.

The subject of a liquor dealer's licence for apothecaries was brought up by Mr. G. H. Schaffer, of Fort Madison, Iowa, who desired to have urgent and immediate steps taken to induce the Government to revoke the necessity of such a licence for the fraternity.

Some of the members present explained the difficulties with which the Government had to contend relating to the sale of liquors by druggists. Throughout the country there are so many who will use their business in drugs as a screen for the sale of liquors, that the Government is obliged to make the conscientious apothecary suffer with those who are guilty, and there appeared to be no way to lighten the burden. It was stated that the commissioner of internal revenue had said that, if druggists were allowed the privilege of selling liquors without a licence, wherever there was now a liquor-shop there would then be a drug-shop, and the Government would receive no revenue.

On Friday the final session was devoted mainly to the reading of papers in answer to queries and volunteer essays.

The committee on exhibition of specimens (J. T. King, chairman) presented a partial report, and a resolution was offered—"That in future all foreign patent or proprietary medicines and nostrums be treated the same as domestic articles of this class, and that they shall not be exhibited or considered at the meetings of this Association." On the vote being taken it was unanimously adopted.

Mr. J. F. Hancock, on behalf of the committee on unofficinal formulas, read some formulas which it was thought desirable to adopt for the sake of uniformity.

Mr. A. E. Ebert presented the formulas of elixirs as adopted by the Chicago College of Pharmacy, and after some discussion on the subject of elixirs, it was referred to a committee consisting of Messrs. William McIntyre, R. V. Mattison, and George W. Kennedy, who were instructed to collate and select formulas, and report at the next annual meeting.

The following is a list of queries reported on at the meeting, and a summary of the reports, taken from the New York *Druggists' Circular*:—

1. American extract of liquorice is regarded by a recent investigator as of superior quality, and is found to yield a large percentage to water. Does not such extract contain an admixture of gum or dextrine? Accepted by Adolph W. Miller, Philadelphia.

In reply to this, it was stated that careful experiments showed that one brand of liquorice had but a small portion of insoluble matter, and was evidently free from any intentional addition of foreign substances, but that some other brands examined contained dextrine.

4. Commercial sulphate of potassium, in the European markets, is stated to contain a large percentage of sulphate of sodium. Is this true of the sulphate found in the American markets? Accepted by P. W. Bedford.

In reply to this query, it was asserted that the sulphate of potassium sold in crystals was pure and entirely free from any sodium salts, but what is known in the market as "slurry," or impure sulphate of potassium, contains a considerable amount of the sulphate of sodium. This "slurry" is not used as a medicine direct, but is employed in the manufacture of glass and as an ingredient in some chemical processes.

5. What is cincho-quinine? Referred to Albert E. Ebert.

This paper detailed at length the commercial history of this much-vaunted article, and also the chemical experiments as to its composition. The name would indicate that quinia is at least a constituent, and the circulars accompanying the article state that it contains the various alkaloids of cinchona; but Mr. Ebert's careful experiments prove conclusively that it is nothing but *cinchonia*, there being *no other alkaloid* present in any of the samples examined, which were all of them obtained from the reputed manufacturer of this "valuable" delusion. Although it has an entirely different appearance from the cinchonia ordinarily found in commerce, this is caused by a modification of the drying process.

8. Powdered blue mass. What is an easy and convenient mode of preparing a mercurial powder to fully represent the officinal blue pill? Accepted by John F. Hancock, Baltimore.

Mr. Hancock gave the following formula as the result of his experience, and one which had proved entirely satisfactory:—

Mercury	284 grains.
Syrup	200 grains.
Sugar, a sufficient quantity.	

Mix the mercury with the syrup, and two hundred grains of sugar, and rub until the mercury is extinguished. Put it aside in a dry room for ten days, rub to powder, adding enough sugar to make the entire weight 1,152 grains, the whole to be thoroughly commingled. The paper stated that the mercury was partially oxidized, and that its action depended upon the oxide thus formed, and that the exposure for ten days was intended to accomplish this object.

The paper elicited considerable discussion, some contending that the intention in all the mercurial preparations in which the metal itself was present was to avoid any oxide, and that the introduction of honey and the trituration with this substance was as far as possible to prevent oxidation.

Professor Remington alluded to his experiments with mercurial powder (hydr. c. cretâ) some years ago, as detailed in a paper before the Association, in which he took the opposite view. It was also stated that no preparation in powder intended as a substitute for blue pill had proved satisfactory. After further discussion Mr. Hancock said that he would experiment further by preparing a powder made with oxide of mercury, and another made with mercury protected from oxidation, and he subsequently accepted a query having this for its subject.

11. How may oleic acid be readily and rapidly prepared, in a condition sufficiently pure for preparing oleate of mercury? Referred to Charles Rice.

Mr. Rice reviewed the various processes which have been published giving formulæ for purification of this acid, and stated that the simplest and best process was to take the crude oleic acid of the market, cool it to 45° F. Express, or better, express it at three different temperatures, the first one at 60° F., the second at 50° F., the third at 45° F.; then add some dilute sulphurous acid, agitate till decolorized, then wash with water until free from the sulphurous acid, and finally separate all water. In making the oleate of mercury, it is best to sift the oxide of mercury on the surface of the oleic acid, incorporating it slowly, and to use no heat. By this manipulation he had succeeded in obtaining a product which was free from any reduced mercury.

13. What is the relative quantity of extract of quassia prepared with water and prepared with dilute alcohol? Accepted by Joseph S. Whall.

The essayist stated that the yield from dilute alcohol was larger, the extract more satisfactory and of a better consistence than when made with water.

16. What is the most desirable solution of quinia for hypodermic injection? Accepted by A. P. Sharp.

Mr. Sharp stated that having found that all the acids usually employed were irritating, he resorted to the use of lactic acid, from which he obtained satisfactory results, both as to its chemical and physiological results. He gave two formulæ, in one of which a small proportion of alcohol was used, in the other bisulphite of sodium was used to preserve the solution from change. The latter formula was:—

Sulphate of quinia	15 grains.
Lactic acid	15 minims.
Water, to make	60 minims.
Bisulphite of sodium.	½ grain.

Rub the sulphate of quinia with a small portion of water to a fine paste, add the acid, then the remainder of the water, and lastly dissolve the bisulphite of sodium in the solution.

17. Why do some of the diluted phosphoric acids of the market form precipitates with tincture of chloride of iron, while others do not? Accepted by Louis Dohme.

Mr. Dohme stated that after he had finished his paper, on repeating some of his experiments with other specimens of phosphoric acid, he had obtained different results from those detailed in his paper, and he would continue his experiments. He attributes the precipitation alluded to in the query to the presence of pyrophosphoric acid. In the discussion which ensued it was stated that the heating of glacial phosphoric acid with water alone would produce the desired result, and be even better than the use of nitric acid, as in the officinal formula, the trouble being to free it from adhering traces of the nitric acid.

19. What are the advantages of making suppositories by moulding over the method of making them by hand? Accepted by George W. Kennedy.

Mr. Kennedy enumerated no less than nine cogent reasons for preferring *hand-made* to moulded suppositories. The principal reasons were, the better distribution of the medicinal ingredients through the mass, the readiness of making a small number, and the satisfactory results he had always obtained by this method. It seems evident that a skilful operator is necessary in order to rapidly make neat-looking suppositories by either method.

20. An examination of commercial carbonates of magnesium for carbonated alkalies. Accepted by P. W. Bedford. The writer stated that carbonate of magnesia, as found in the market, contained a small quantity of lime and soda, with traces of potassa and sulphuric acid. They were, however, minute in quantity, and could not probably be entirely freed from traces of these substances without increasing the cost too much for the large manufacturing processes.

22. Does water extract all the purgative principles of rhubarb, and is the alcoholic percolate of rhubarb, after its exhaustion with water, inert? Accepted by Charles A. Heinitsh.

Mr. Heinitsh states that water does not extract all the purgative principles in rhubarb. After carefully percolating rhubarb with water until no soluble matter was taken up, then drying, and again percolating it with alcohol, the latter liquid dissolved some soluble extractive matter, which, when evaporated to a pilular consistence, proved laxative in doses of six to ten grains, and purgative in doses of over twelve grains.

26. To what pharmaceutical uses can cosmoline be put? Accepted by Joseph L. Lemberger.

Mr. Lemberger stated that he had used cosmoline in a variety of forms as ointment, cerate, and fluid preparations, and found it to be a valuable substitute for lard and similar unctuous bodies. When combined in suitable proportions with yellow wax he deems it preferable to lard as ordinarily to be found, while as a healing agent he believes it to be far superior. He gave numerous instances in which he had seen its efficacy in severe burns, as also in other applications.

Considerable discussion ensued after the reading of this paper. The general opinion expressed was that cosmoline was no more or less than a purified paraffin oil, and that its various forms were only modifications effected by heat. The statements made by its proprietors were doubtless true, that they did not treat it with any chemicals; but as it was a process which they endeavoured to keep secret, and protected by a trade-mark or patent, it was the duty of pharmacists to seek some suitable substitute. That the article possesses merit seemed to be apparent to all, but the opinion prevailed that all this merit could be found in paraffin oil.

29. What preference is shown to graduates in pharmacy, as compared with non-graduates, and how do their salaries compare? Accepted by P. Balluff.

Mr. Balluff stated that graduates always procure positions more readily, and at better compensation, than can be commanded by non-graduates. This experience was not confined to New York, but his correspondence led him to believe it was almost universal.

30. How do the salaries of drug clerks compare with the salaries of clerks in other businesses, and with those of skilled mechanics? Accepted by H. N. Rittenhouse.

The reply of Mr. Rittenhouse was very voluminous, and embraced statistics showing the compensation paid to all classes of labour. Although the compensation of drug clerks seems liberal, yet when their hours of labour are compared with the hours of skilled mechanics, the ratio of time given by drug clerks is greater than any other class of labour for the same amount of money received as compensation. As only the most competent drug clerks can expect to receive liberal salaries, it depends upon the young man as to what he shall be valued at. It is, therefore, an incentive to all to attain the highest grade of competency, either considered as to ability to command a liberal salary, or the requisites to successfully conduct a business for himself.

33. What is the quality of the iron by hydrogen of the market? Accepted by J. L. A. Creuse.

The paper of Mr. Creuse was very exhaustive in its research. Selections were read showing the analysis of specimens of iron by hydrogen, the analysis proving that there was a vast difference in the samples examined.

35. What is the state of purity of commercial santonin obtained from various sources? Accepted by Frederick Hoffmann.

Dr. Hoffmann examined a number of samples obtained in various cities of the Union, and found all to be pure except one sample. There was, however, quite a difference in the appearance of the crystals, but this he attributed to the fact that they were obtained from different liquids.

Professor Remington stated that santonin had been seen of German origin, which contained a large percentage of ground mica.

39. An essay on granulated effervescent compounds. Accepted by R. V. Mattison.

The essayist read quite a lengthy paper, stating that most of the imported "granules" were unreliable; that, with the exception of a single foreign manufacturer and two American producers, those of citrate of magnesia were entirely free from this salt. The general process adopted in their manufacture was to combine equivalent weights of citric or tartaric acid with bicarbonate of soda by means of absolute alcohol; make them into a paste with the medicinal ingredient desired, and a small amount of sugar; then dry carefully, and afterwards sift them through suitable sieves, the fine powder which passed through the finer sieve to be worked over with the next lot of the same kind. The great difficulty was to produce them of a satisfactory white colour, which he asserted could not be done readily on a small scale. It was necessary that *absolute* alcohol be used, as a minute quantity of water would spoil the whole batch.

There was considerable criticism upon the paper, as the majority of those present thought it should have given more practical information, while others discountenanced the idea that for such preparations they should depend upon the wholesale manufacturer. It was the duty of the pharmacist to be competent in all branches, and the object of their meetings was not to encourage secret preparations, but to extend useful and practical information to all.

42. What merit has petroleum benzine as a solvent for the extraction of oleo-resinous drugs like chenopodium, etc.? Continued to Joseph P. Remington.

Professor Remington stated that his paper of last year on the solvent properties of petroleum benzine had proved the fact that it was not a good solvent for buchu, and since then other experiments had proved that it was not available for any of this class of oleo-resinous drugs, as after it failed to extract any more active soluble matter alcohol would still remove a large quantity. He therefore reported against its use as a solvent for these drugs.

43. Does not the acknowledged value of colchicum, and its liability to vary in activity, suggest the preparation of a working formula for medicinal colchicia as a new pharmaceutical? Continued to Ottmar Eberbach.

Mr. Eberbach's conclusions are that the alkaloid exists in small quantities, and is too expensive an extract to make a satisfactory pharmaceutical product from which to prepare any remedial agents. He exhibited specimens of the crude and crystallized colchicia in connection with his paper.

48. An essay on cleanliness as a pharmaceutical virtue, and especially on the means and methods of cleaning bottles, mortars, and vessels of all kinds in daily or occasional use. Continued to J. M. Ayers.

An amusing and interesting essay extolling the virtues of industry and soap, with sundry bits of good advice as well as sarcasm.

51. What are the degrees of strength and the purity of the so-called chemically pure mineral acids of the different manufacturers? Continued to P. W. Bedford.

The reply to this query gave the results of examinations of C. P. acid, obtained from various manufacturers. The acids examined were hydrochloric, sulphuric, and nitric. The sulphuric and nitric acids fall below the U. S. P. standard of specific gravity, while of the specimens of hydrochloric acid examined, two of them were above the standard. None of the acids contained any great amount of impurities, and, with the exception of the last two-named manufacturers, the others may be said to be very good articles, as the poorest of the others contain only traces of impurities, or sufficient to respond slightly to the tests employed.

Volunteer Papers.

A very exhaustive essay on "The Officinal Veratrums" was presented by C. L. Mitchell, and it was understood that it was a special competition for the Ebert Prize, which was founded last year.

The essay was divided into three portions, botanical, chemical, and physiological. The first portion reviewed all the characteristics of the veratrums; the second portion a lengthy chemical examination of each variety of veratrum, with their reactions, products, and characters; while the physiological examination detailed the action of the various substances isolated upon rabbits and other animals.

The deductions from the various experiments in connection with this paper are stated by Mr. Mitchell to be:—

1. There exists no such alkaloid as viridia.
2. Bullock's viridia is identical with, and probably was, jerira.
3. There is a distinct alkaloid in *Veratrum album*, differing from veratria and veratroidia.
4. The resin of *Veratrum album* is in itself nearly inactive, and owes whatever power it may possess to the presence of veratrolla.
5. The alkaloids do not exist in sufficient proportion to be profitably extracted.
6. Jerira does not exist in the seed of *Veratrum Sabadilla.*
7. Jerira and sabadilla are probably not identical.
8. Couërbe's "le vératrin" is a mixture of resin and veratria. Veratrolla acts as—(1st) Local irritant; (2nd) Irritant emetic and cathartic; (3rd) A direct depressant to the circulation; (4th) A powerful nerve and muscle poison, producing death by either paralysis or suspension of the action of the heart-muscle. Its action on the nervous system has not been studied. It is probably a spinal and motor depressant, like the other alkaloids of the group.

A volunteer paper, by James R. Mercein, on home-made chemicals, was very favourably received, as it urged the preparation of many of the chemicals now usually purchased. The paper was accompanied by some dozen specimens of chemicals prepared by Mr. Mercein.

Dr. W. H. Pile presented three volunteer papers. One on bromide of ammonia, gave a new and easy process for its manufacture. It may be briefly stated thus :—Into a five-gallon stone jar (which should be set in cold water) introduce—

Distilled water	4 pints.
Bromine	1 pound.

The bromine is poured down a funnel tube, long enough to touch the water, and afterwards add the water of ammonia, *in small quantities, avoiding much increase of temperature*, and the mouth of the jar covered with a glass plate. About two pounds of water of ammonia will be required. When the bromine has been entirely converted into bromide of ammonia, the solution may be evaporated with constant stirring as the process nears completion, in order that the salt may be obtained in a granular form.

The second paper was a brief one, on the preparation of phosphuretted resin.

The third paper was on a modification of hydrometers, by which a single hydrometer may be adapted for various uses in manufacturing. A glass hydrometer, having the upper extremity open and fitted with a cork, has a single mark made on the tube, and mercury is poured into it until it floats in distilled water at the level of the mark. The tube and its contents are now dried and weighed. To make this available for other liquids, it is only necessary to multiply the weight by the desired specific gravity of the liquid to be examined, and make the hydrometer correspond in weight by the addition or removal of a sufficient amount of mercury. If now placed in the liquid to be examined it gives an indication as to the density of the liquid. This instrument is not intended for delicate work, but rather that persons in manufacturing establishments may readily make hydrometers for special uses.

The only remaining paper read was by Clay W. Holmes, of Wilkesbarre, Pa., on castor-oil emulsion, for which he gave the following formula:—

Castor Oil.	6 fluid ounces.
Acacia	1 troy ounce.
Syrup	1 fluid ounce.
Glycerine	1 fluid ounce.
Water	3 fluid ounces.
Brandy	$\frac{1}{4}$ ounce.
Extract Vanilla	$\frac{1}{4}$ ounce.
Oil Cinnamon	5 drops.

Mix, and make emulsion.

Parliamentary and Law Proceedings.

Prosecution for Imitating Trade Marks.—Clarke's Blood-Mixture.

At the Middlesex Sessions, October 14, before Mr. Serjeant Cox, George Herbert Clarke, a chemist, of Shoreditch, was indicted, under the statute of the 25th and 26th Victoria, for that he did alter a trade-mark—to wit, one of "Clarke's World-famed Blood Mixture;" a second count charged him with causing such alteration to be made; a third count charged him with forging such trade-mark; a fourth count charged him with applying such forged trade-mark; and a fifth count charged him with applying a counterfeit trade-mark. There were other counts still further varying the offences.

Mr. Montagu Williams prosecuted; Mr. Besley appeared for the defendant.

The defendant having pleaded not guilty, Mr. Montagu Williams said the real question the jury would have to consider was whether the defendant had or had not copied the trade-mark of the prosecutor. The prosecutor was Mr. Francis Jonathan Clarke, of Bracebridge Hall, near Lincoln, a chemist, but although a chemist of Lincolnshire, he was well known throughout the kingdom. He registered a mixture called "Clarke's World-famed Blood Mixture," which was widely advertised and sold throughout the country. On the 18th of March, a person of the name of Crook, the London agent of Mr. Clarke, called upon the defendant, who is a chemist in Shoreditch, and inquired of him whether he would undertake the agency of Clarke's Blood Mixture for that neighbourhood. The defendant said he should like such an agency very much, and at his request he was supplied with a large quantity of "Clarke's World-famed Blood Mixture," all bearing a particular label, which was entered at Stationers' Hall, and it bore particular lines upon it. Subsequently Mr. Crook called upon the defendant, who said he liked the agency very well for the sale of this medicine, and upon that he was furnished with a thousand bills, and the defendant's name was printed at the bottom of them. It was subsequently found that the defendant was selling what he called "Clarke's Blood Renovator," a mixture of his own, instead of "Clarke's Blood Mixture," done up in similar bottles and with similar labels, and calculated to deceive, by substituting one for the other. Some conversation took place as to this substitution, and a prosecution was at once commenced. All the prosecutor wanted was to protect his own property, and make himself safe without having recourse to a criminal prosecution. If the defendant would give up the labels and apologize for what he had done, he would then be willing to give up the prosecution. The defendant, George Edward Clarke, had been mixed up with a Montague Clarke, under the name of "Dr. Clarke," for the sale of this medicine. Both had apologized, and having read the apology, he did not propose to offer any evidence. The apology was as follows :—"I, Charles Montague Clarke, do hereby acknowledge that I, under the spurious title of Doctor of Medicine, have illegally infringed and printed your trade mark 'Blood Mixture,' and copied your advertisements, labels, handbills, and caution, with intent to deceive the public. And I, George Herbert Clarke, do hereby acknowledge that I, under the title of pharmaceutical chemist, have prepared and sold for the said Charles Montague Clarke a certain compound called 'Blood Renovator.' Now, we, the said Charles Montague Clarke and George Herbert Clarke, do hereby, in consideration of your consenting to offer no evidence against the said George Herbert Clarke, on a true bill found against him by the grand jury of the Middlesex Sessions on the 8th day of October inst., undertake to agree to discontinue such practices, and to hand over to your solicitor forthwith all wrappers, handbills, advertisements, circulars, and bottles containing the stuff relating to the said spurious compound called 'Blood Renovator,' and we humbly apologize for having resorted to such practices.—Charles Montague Clarke, George Herbert Clarke. Signed in the presence of Henry Poull and J. Haseldine, clerks to Mr. J. Seymour Salaman, 12, King Street, Cheapside, solicitor to the Trade Mark Protection Society." Under these circumstances, on being consulted, he said this was a proper termination of the proceedings, and therefore he did not propose to offer any evidence in support of the prosecution.

The Jury then returned a verdict of "Not Guilty."

Mr. Besley said that, setting aside all technical objections as to the infringement of this trade-mark, as Mr. Clarke had spent a large sum of money in advertising this preparation, it was unfair on the part of the defendant to sell anything as a colourable imitation.

Mr. Serjeant Cox concurred in the course that had been taken, and ordered the defendant to pay the costs of the prosecution.—*The Daily Chronicle.*

Prosecutions under the Adulteration Act.

"Liebig's Liquid Extract of Beef."

At the Bradford Borough Court, on the 9th inst., John Knight, of 4, Nelson-square, Horton-road, was charged with selling an article called Liebig's Liquid Extract of Beef, which was alleged to be a different article from that which was actually sold under that name.

The Town Clerk said that he had nothing to say either against the extract or against those who sold it, his contention being that the defendant had sold an article which was not what it purported to be, and which was different from what it was described to be by the vendor. It was stated to be "the only beef extract that does not require cooking or warming, it being in the form of a liquor. It is composed chiefly of pure extract of beef, obtained from the best parts of the animal, wine, a small quantity of fine old brandy, and quinine." It was said to be highly nutritious and easily digested, was specially recommended to ladies in a delicate state, and the opinion of a Dr. Sewell was quoted : "I can recommend it as convenient, palatable, and easy of digestion." The Town Clerk urged that representations of this kind were mischievous, and calculated to mislead, as the so-called "Liquid Extract of Beef" contained a very minute portion of beef, no quinine, no Madeira wine, and no brandy, but something else to make it palatable. Directions were given on each bottle to the effect that "invalids may take a wine-glass full three times a day with great advantage. This quantity has been found to sustain life for months, when the patient could not retain any other kind of food on the stomach." He urged that all this was misleading, as the extract was stated to be "composed chiefly of pure extract of beef," while it was actually nothing of the sort. A couple of bottles of the extract were purchased of the defendant by Inspector Barker. The extract was analysed by Mr. F. M. Rimmington, borough analyst, and it was found to consist of a very small portion of beef, Tarragona wine, sweetened with sugar, flavoured with pimento or allspice, slightly aromatic in flavour, and containing 15 per cent. of pure alcohol. Evidence was given by Mr. Rimmington, who stated that he considered the extract was injurious to health when improperly recommended, as it was in the hand-bills given to purchasers. There might be no such man living as Dr. Sewell, and a false representation was made about the extract. It was not chiefly composed of beef, as there was only a trace of beef. There was no quinine, no brandy, no Madeira wine, and it appeared to him to be merely a sly method of drinking. Mr. H. Butterfield, the Medical Officer of Health, said that the extract would be injurious to pregnant women, and could not take the place of animal food, as it was injurious to give alcohol instead of beef. It could not be good as a food as it was described, and he considered that if the extract were taken instead of food, the person taking it would not live long. Mr. Terry, for the defendant, urged that his client was quite innocent of any intention to mislead. He had obtained the extract from Messrs. Digby, Gandy, and Co., of Liverpool. That firm had purchased the right to sell it from a Glasgow firm, and the extract that Mr. Knight received was part of the old stock which had been purchased along with a number of hand-bills. The Liverpool firm had since improved the extract, had patented it, and it was selling largely, so that they could hardly supply the demand. He went into a lengthy argument to prove that his client had done no wrong, but the magistrates (Messrs. J. Farrar and Ald. Mitchell) were of a different opinion, and the defendant was fined 40*s.*, with £2 10*s.* expenses, or one month in default. Mr. Terry then applied for a case, but the Bench refused. He then intimated his intention to appeal at the sessions, and later in the afternoon an undertaking to this effect was entered into by the defendant, John Knight, and Messrs. Edward Theodore Digby, and Chris. Gandy.—*Leeds Mercury.*

In reference to the foregoing case we have received a letter from Messrs. Digby, Gandy, and Co., of Liverpool, stating that the article alluded to is "Liebig's Liquid Extract of Beef and Tonic Invigorator," manufactured by Gerald Gordon and Co., of Glasgow, New York, and Montreal, received by Mr. Knight as samples, but that it is not now offered for sale in this country, and is not the "Liebig's Liquid Extract of Beef," manufactured and patented by them, and the quality of which they are in a position to guarantee.

Adulterated Mustard.

At the same sitting of the court, Charles Hill was charged with selling mustard that was adulterated. Inspector Booker applied at the defendant's place for some mustard from the bulk, but the defendant's man refused to sell from the bulk, and Booker bought a quarter-pound tin. The mustard was analysed by Mr. Rimmington. It was stated on the outside of the can that it consisted of pure mustard, farina, and *choice condiments*, but the analyst found that it consisted of mustard, wheat flour, and turmeric, but it was not injurious to health. The wheat flour was added to increase its bulk, and the turmeric to colour it. Booker stated that no declaration was made by the man from whom he bought it as to what the mustard contained, and he did not observe the specification on the exterior of the can. The mustard was Colman's. Mr. Berry, for the defendant, urged that his client was not responsible, as the can stated what the mustard consisted of, and he held that that was a sufficient declaration. The magistrates, however, thought otherwise, and a penalty of 10*s.* with 8*s.* costs, was inflicted, or fourteen days in default.

WHAT IS A SUFFICIENT DECLARATION OF ADMIXTURE?

At the Edmonton Petty Sessions, on the 28th ult., Mr. Robert Hockey, grocer, of Colney Hatch, appeared upon an adjourned summons charged with selling, as a pure article of food, mustard that was adulterated with 20 per cent. of flour and turmeric. The defence on the first hearing was that the label on the packet to which attention had been called, stated "This is an admixture in which no injurious ingredient had been used." The case had been adjourned for the production of a copy of a judgment in a superior court, to enable the bench to decide whether this was a sufficient declaration. The judgment quoted was that in the appeal of *Pope v. Tearle*, heard by Lord Chief Justice Coleridge, and Justices Brett and Grove, before reported in this Journal (vol. iv., p. 98); but as in its extended form, published in last month's Law Journal Report, Mr. Justice Groves gives another reading to the words *"and no other,"* which it has been asserted were inserted in the Act with special reference to drugs, we reproduce it here:—

"Lord Coleridge: I think the respondent is here entitled to our judgment. There are two sections of the Act (35 and 36 Vict., cap. 74) which bear upon this case, and it appears to me that the facts bring him within neither of them. [His Lordship here read the 3rd section.] Now, it appears to me that the true and reasonable construction of the Act interprets it thus—Whereas the phrase in the former section contemplated the case of the adulteration being by means of some noxious ingredient, the 3rd section went on to say, if an article of food or drink be mixed with a substance not noxious, but fraudulently added for the purpose of increasing the weight or bulk, and it be sold by a person knowing this who does not declare it, then such person shall be guilty under section 2. The respondent here is not within it. For though he sold an article so mixed, yet, by language and by label, he affected the purchaser with knowledge, and so did declare the admixture. He is not therefore within section 3. But supposing that he had not declared the admixture, and had sold, then he would have been brought within section 2. As it is, however, he is not within the latter section, for the simple reason that he has not here sold as unadulterated any article of food which was adulterated. Justice Brett: I am of the same opinion. Justice Grove: I read the Act in this way:—Sections 1 and 2 contemplate the mixing of noxious ingredients in articles of food and drink. The 3rd section, in order to avoid any doubt as to what adulteration is, says that the admixture of foreign substances, whether noxious or innocuous, is all the same adulteration. Is there anything in the section to make it necessary for the seller to declare what is the substance and quantity of the materials mixed? I think not. The words '*and no other*' in the 3rd section may well mean no noxious substance—nothing, that is to say, except for the purpose of increasing the weight. Judgment must, therefore, be given for the respondent (the grocer)."

After hearing the reading of this decision, the Bench unanimously dismissed the summons.

ALLEGED ADULTERATION OF PEPPER.

At Highgate, John Clevely, grocer, Colney Hatch, appeared in answer to an adjourned summons charging him with having sold adulterated pepper. Mr. Terry, solicitor, appeared for the defence. The inspector under the Adulteration of Food Act, deposed to purchasing two ounces of pepper at the defendant's shop, and Dr. Redwood, the county analyst, certified that it contained five per cent. of sand and inorganic matter, but that this adulteration would not be injurious to health. Henry King deposed that he represented the firm of Murray and Dean, formerly Sidney and Co., wholesale grocers, 41, Ludgate Hill, and sold the pepper to the defendant as pure. Witness bought the pepper of Messrs. Tomlin and Rendell, of Eastcheap, under a written guarantee that it was pure. Mr. Terry now produced a certificate from Dr. Hassall, the analyst, to whom a portion of the pepper bought by Mr. Faulkener, as well as samples from the bulk of Messrs. Murray and Dean's stock, had been sent. The certificate was as follows:—"The Analytical Sanitary Institute, 14, John Street, Adelphi.—Report of two samples of pepper received from Messrs. Murray and Dean, 41, Ludgate Hill: I have analysed with the greatest care two samples of black pepper sent to me to compare their composition with that of genuine black pepper. The first sample yielded on incineration 10·45 per cent. of mineral matter, containing 3·95 per cent. of silica or lead. The second sample, labelled 'Clevely,' contained 10·35 per cent. of mineral matter. Both samples contained small quantities of magnetic oxide of iron. Two samples of whole pepper berries obtained for the purpose of comparison gave only 4·60 and 4·00 per cent. of ash respectively, and contained but 0·12 and 0·10 per cent. of sand, while white decorticated pepper berries yielded as little as 1·56 per cent. of ash, which was non-magnetic. It is clear, therefore, from these results that both the samples sent for analysis contain a large excess of mineral matter, especially sand." Mr. Terry contended that this did not amount to adulteration. He argued that the sand was natural to the pepper, as it was not put in, but was from the stones by which it was ground. Moreover, the pepper berries when gathered fell to the ground, and the sand adhered to them. He called Mr. Cass, a spice grinder, of 5, Dockhead, who deposed that he ground about 100 tons of pepper a year for Messrs. Tomlin and Rendell. He fetched the whole pepper from the docks, and it was ground in stone mills, which certainly wasted a little. Mr. Nicholson said that "French burrs" (the stone used for millstones) gave off silica; but it was quite possible to grind pepper in a mill without stones. The Bench, after retiring to consult, decided that they must dismiss the summons, as they did not think there was any intention to adulterate the pepper; but Mr. Faulkener could have a case stated if he wished. Mr. Faulkener said he did not wish it. Mr. Nicholson said they also had considerable doubt about the meaning attached to the word "adulterate." Mr. King said that Messrs. Murray and Dean intended in future to manipulate the pepper themselves on their own premises.—*Grocer.*

ALLEGED ADULTERATION OF MUSTARD.

At the Mansion-house Police-court, on Thursday, Henry Parr, grocer, of the Trafalgar-road, Greenwich, was charged with selling adulterated mustard. Mr. Spencer prosecuted; Mr. J. B. Smith defended. It was proved that an ounce of mustard was purchased at defendant's shop, and placed in a bottle, which was corked and sealed in the presence of the manager. On hearing it was purchased for the purpose of analysis, the manager took out another ounce from a drawer in paper, and had the same sealed by the inspector. A portion of that purchased had been submitted to the public analyst, Mr. Wigner, whose certificate was produced to the effect that the mustard was adulterated with more than 30 per cent. of starch, which would not be prejudicial to health if taken as food. Mr. Smith said that the mustard in question was supplied in casks by Mr. Armistead, of Leeds, and the reason that a sealed packet of the mustard had been taken was that the mustard contained in the drawer might be analysed by a private analyst. This had been done by Dr. Tidy, who had certified that there was no adulteration whatever. He had, therefore, to ask for a third analysis, the decision in the case to rest upon the result; the portion to be analysed being that left from the part analysed by Mr. Wigner. Mr. Spencer said he had agreed to this further test, and that the analysis should be made by Dr. Heisch. Mr. Patteson accordingly adjourned the summons *sine die*.

SUPPOSED IMPROPER USE OF A MEDICINE.

The inquiry into the circumstances attending the death of Mr. William M'Kee, at Dundonald (see before, p. 275), was resumed on the 5th inst. Dr. Hodges, Professor of Medical Jurisprudence in Queen's College, Belfast, reported that he had examined the contents of the stomach and found traces of morphia. In one partly used bottle of medicine he had found ·306 grain of acetate of morphia, and in another ·665 grain: the former bottle when full would have contained 1 grain, and the latter about $2\frac{2}{3}$ grains of morphia. There was no label of any kind on either of these bottles. After some further evidence, the jury returned a verdict that the death was caused by an overdose of morphia, which resulted from the bottles containing the said poison being not properly labelled, and without any directions thereon as to how and what quantity should be taken, but that who supplied the said poison there was not sufficient evidence to show. They added a recommendation that the Crown should investigate the matter further, in order that the guilty party or parties may be prosecuted.

Reviews.

A TREATISE ON PHARMACY. By EDWARD PARRISH. Fourth Edition. By THOMAS WIEGAND. Philadelphia: Henry Lea; London: Baillière, Tindall, and Cox. 1874.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the Transatlantic press. 'Parrish's Pharmacy' is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. It is impossible to look upon the fourth edition of this book without a double feeling of regret: Edward Parrish was unable to finish this edition, owing to his sudden death in the autumn of 1872, and now we find that the friend to whom this labour of love was dedicated is also no more.

In two short years the Americans lost two of their ablest men and worthiest citizens. The work, however, left by one of them, the writer of the book under review, was not allowed to be lost, and thanks to the judicious editing of Mr. Wiegand, the posthumous edition of 'Parrish' has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.

'Parrish' is essentially a pharmacy book, or, in other words, it is the work for the man who wishes to study the *art* of pharmacy. It is not a book that we should recommend a student to study his pharmaceutical chemistry from; in fact, the chemistry is weak, and interlarded with a mass of extraneous details which are not suitable. In other words, 'Parrish' is more a book for the reference of the advanced student, or as the companion of the pharmacist's shop, than a work that would be of much use to the learner such as we understand the student to be, viz., a young man anxious to pass an examination. The author, however, had it in his plan to make it a text-book for professors of pharmacy. And the syllabi, as they are called are introduced very extensively for this purpose. The attempts to classify as much as possible in a tabular form all the materia medica and also the preparations, form useful compilations, and we know no work where this system has been more carefully and industriously carried out.

The matter, although somewhat re-arranged and transposed, is much of the same fashion as the last edition, with this exception, that it is much more full and extended. It is this fact that makes us object to the book for the use of students. Such works, in our opinion, are not suitable to teach, from their very fulness and complexity. The aspirant is obliged to take to cramming in self-defence, and he loses that method and perspicuity which are so essential to a sound foundation of learning in any science or art. Let him fill up the filigree work as he advances in his art, but a clear understanding of the skeleton upon which his superstructure is raised is absolutely essential.

To conclude our criticism so far as it may be at all called adverse, we must point out that the notation is rather loose. This is, no doubt, to be excused in a very large work like the one before us, because the conversion of the old notation into new must really be an Herculean undertaking; but as an example of what we mean, whilst barium is made a dyad in connection with oxygen on one page, we find it a monad when tied to iodine on the next.

Part I. is one of the divisions which stamp this book with usefulness; it is on the "furniture and implements" of the craft. It is true, as the author says, that no directions can be given to suit all conditions and circumstances for the arrangement of the pharmaceutical store, but no practising pharmacist will read this and not put by the book a wiser man.

The first chapter of the second part is devoted to the consideration of pharmacopœias. The author points out the necessity of an acquaintance amongst well-educated pharmacists with the standards of other countries. International communication is rendering this more imperative every day, and the example of consolidation set by the British Pharmacopœia is a move which, if extended, would benefit the three most interested parties vastly, if the initiative could be taken with regard to our own and the U.S. dispensatory.

After this we have a description of the necessary apparatus and their uses, and the chemical processes are explained. We still find the extraordinary jumble of ideas as regards old and new notation perpetuated through this part. We have already referred to this subject, but it is too important to pass over in silence. Thus we are told that "the formation of nitric acid in heating equal weights of nitrate of potassium and sulphuric acid is thus explained in accordance with the views of modern chemists"!

"$KNO_3+HSO_4=KSO_4+HNO_3$,"

and so on.

Now, as O is given as sixteen, and sulphur as thirty-two, there is evidently great confusion somewhere. The above equation means nothing, and it is calculated to mislead the student.

The work will be found invaluable to the practical man, from the numerous and varied formulæ for the compound mineral syrups which are now becoming as popular in our practice as on the other side of the Atlantic.

Part IV. is devoted to pharmacy in its relation to organic chemistry. The syllabi in this section are very full, and will be found very useful.

The chapter upon oils, particularly essential oils, is invaluable, and contains practical information in a concise form which we doubt can be found in any other work.

Part V. is the fullest and also one of the most important sections; it is headed "Pharmacy proper" (Galenical pharmacy). It contains many hints upon the subject of apparatus; amongst others we may mention Wiegand's improved clasp or ring for the retort stand, which is novel, and certainly possesses advantages over the old plan. The part containing the binding screw is open on one side, so that when the screw is loosened it can be slipped off laterally without moving it up the rod. The Galenical pharmacy is treated so fully, in fact is nearly half the work, both as regards the extent and importance, that we could not give it full justice without extending this review to much more than its legitimate space. It forms an encyclopædia of formulæ seldom met with, and at the same time is interspersed with manipulatory details which greatly enhance the value of what may be termed an important book. Parrish's 'Practical Pharmacy' is got up well, as all the better class of American books are, as regards their type, whilst the binding is exceptionally good, and forms a marked contrast to the usual boards, that certainly may temporarily cover, but assuredly do not bind—the books of publishers.

Nouveau Dictionnaire des Falsifications et des Altérations des Aliments, des Médicaments et de quelques Produits Employés dans les Arts, l'Industrie, et l'Économie Domestique; par J. L. Soubeiran, Professeur à l'École Supérieure de Pharmacie de Montpellier (J. Baillière et Fils, Paris).

M. Soubeiran opens his work with a preface, the commencement of which contains an excuse for adulteration in France, on the ground that the blockade established against France by the whole of Europe at the commencement of the present century, forced her to seek substitutes for her exhausted supplies; but he observes that the English, who have not the same excuse, practise adulteration to an equal extent. This certainly looks like making an excuse where none is wanted, particularly as a few lines farther on, after various reasons for the suppression of adulteration, he sums up in the following words:—"Adulteration, which is always the result of immoderate competition, ought to be severely punished, and commerce ought to be ashamed to lower itself to such work." The French definition of adulteration is also given—namely: "Purposely introducing into a product any other substance, whether inert or injurious; but accidental substitutions or admixtures, which may arise either from inadvertence or from defect in the manufacture, are not to be considered as adulterations." This definition is certainly rather lax, and does not in any way tend to elucidate the question which has for some time troubled the English legislature.

The work commences with a few pages descriptive of chemical apparatus and tests, which seem useless in a work like this, as any one attempting to carry out the analytical schemes described in the book should possess more knowledge than a few pages could convey. We are afraid, moreover, that this would give some confirmation to the already too popular, but false, notion that the requisite knowledge to enable any one to undertake analyses can be obtained by a short course of chemical study. The remainder of the book consists merely of a compilation of information respecting the various impurities in articles of food, medicines, etc., and the methods for detecting them, derived chiefly from Hassall's work on adulteration, and the various works on materia medica in general use; but it contains very little new or original work. Indeed, in some cases the methods given are out of date.

Some few errors have also escaped revision. Thus, acetic acid is said to boil at 120°, and solidify at 170°; hydrochloric acid, containing sulphurous acid, is said to give a precipitate of sulphite of barium with chloride of barium. On page 34 there is a substitution of the word citric for tartaric acid. Under hydrocyanic acid no mention is made of any process for estimating its strength; and under cyanide of potassium the volumetric process of Liebig is not mentioned. The statement, on the authority of Mr. P. L. Simmonds, that 250 tons of coculus indicus is consumed yearly by the English brewers is also open to doubt. Chamomile flower-heads are stated to have a flat receptacle, and no mention is made of the paleæ as the characteristic by which to distinguish them from the various flowers often substituted for them. Under bleaching powder no mention is made of the volumetric process by means of sodium hyposulphite, but the process given is that of Gay Lussac, depending on the quantity of arsenious acid capable of being converted into arsenic acid by the bleaching powder. Morphia is stated to be *soluble* in water, but the proportion is not stated. In testing for chloride in iodide of potassium, it is said that when nitrate of silver is added to the solution, and then ammonia to dissolve the precipitated chloride, the liquid will give a fresh precipitate with more nitrate of silver; nitric acid is doubtless intended.

Under milk, in order to extract the butter-fat, we are told "to filter milk through a triple filter, and when all the serum has run through, to exhaust the filter, etc., with ether, in order to dissolve the fat." No mention is made of first coagulating the milk to separate the curd from the serum.

A method of testing milk, precisely similar to that proposed by Mr. Horsley, of Cheltenham, is given, and a French chemist is named as the author; but no reference is given to the work in which it was originally published. We are unable to state, therefore, whether it would interfere with Mr. Horsley's claim to priority of discovery.

Under tannin the gelatine process is omitted; and in the method given of estimating tannic acid by means of tartar emetic, one of the most essential points—namely, the addition of chloride of ammonium—is altogether left out. The proportion of tannin in tea is also stated to be 30 to 40 per cent. in one part of the book, and from 12 to 20 per cent. in another.

On the whole, the book will doubtless be useful for the purpose for which, probably, it is intended, and will furnish to pharmacists or others who possess the knowledge requisite for discriminating between the good and the bad, a book of reference respecting methods of detecting adulterations. But it is scarcely the work which the high reputation its author justly bears would have led us to expect.

BOOKS RECEIVED.

Butter: its Analysis and Adulterations, specially treating on the Detection and Estimation of Foreign Fats. By Arthur Angell, F.R.M.S., and Otto Hehner. London: Wyman and Sons. 1874. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 21st September, 1874, Mr. Frederick Telfer, Pharmaceutical Chemist, who for many years carried on business in Corn Market Street, Oxford. Mr. Telfer had been a Member of the Pharmaceutical Society since 1842.

On the 1st October, 1874, Mr. Joshua Monkhouse, Pharmaceutical Chemist, of Liverpool. Mr. Monkhouse was a Member of the Pharmaceutical Society.

On the 5th September, 1874, Mr. Sutton Marshall Simpson, Chemist and Druggist, of Union Street, Bristol.

On the 30th September, Mr. Henry Fisher, Chemist and Druggist, of Lower Gornal, Staffordshire.

On the 6th September, Mr. John Scholfield, Chemist and Druggist, of Todmorden, Yorkshire.

On the 7th October, Mr. C. G. T. Williams, Chemist and Druggist, of Broad Street, Bath.

On the 8th October, 1874, Mr. Edward Schindler Griffiths, Chemist and Druggist, of Brighton, late of 47, Mortimer Street, Cavendish Square, London, W.

Notes and Queries.

[409.] DEPILATORY.—In reply to W. W., the best and safest depilatory is sulphide of barium made into a paste and applied to the part for five minutes, then scaled off with a bone knife.—Chemicus.

[414.] PREPARATIONS FOR THE TEETH.—Can any one give me a recipe for "Cherry Tooth Paste," also, "Soap Bark Tincture for the Teeth"?—Chemicus.

[415.] SYRUP OF HYPOPHOSPHITE OF IRON AND LIME.—"Syrupus" wishes to be supplied with a formula for Syrup of Hypophosphite of Iron and Lime.

Correspondence.

**** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Pharmaceutical Education.

Sir,—The eloquent and forcible address delivered on Wednesday last by Mr. Giles to the students of the Pharmaceutical Society ought not to be allowed to pass without comment, by way of enforcing the important principles which it enunciates.

And this all the more so since the speaker informed his audience that he was retiring from the practice of pharmacy.

I shall not venture now, and in this public fashion, to say all I feel impelled to say as to the ability and the attainments, crowned with fearless integrity, which have marked the career of this *facile princeps* of pharmacy. But this much, with propriety, I may say: we are thankful and proud to have had such men enrolled in our ranks—men capable of achieving distinction in any walk of life.

Bristol is pre-eminently wealthy in this respect. In what other town or city of the United Kingdom, the metropolis excepted, is such a trio of representative men to be found as hitherto have instructed and gladdened our meetings by their presence?

The influence of such leaders of thought is by no means confined to such meetings.

The *indirect* influences are greater than the *direct*, in the action of mind on mind, character on character. Principles introduced in living forms must ever be more potent as incentives to action than the most correct and faultless of systems continuing in the abstract only.

Mr. Giles retires from our ranks with the best wishes of all pharmacists that health and happiness may attend his days.

And now, Sir, let us for an instant pause and consider his valedictory address, the motto of which appropriately might be "*Prospiciens et respiciens.*" The retrospective portion of it will exercise an influence on our minds, determined by the age and position of his audience.

Many of us no longer young can endorse the accurate delineation of the state of pharmacy some thirty years ago or more. Keenly feeling the disadvantage at which we have been placed from the lack of early training, we are thankful that our sons start from a platform of 'vantage ground, which it will be their sin as well as their folly should they neglect.

The earnest and impassioned utterances of the address must prove a powerful stimulus to work on the part of the young men just entering the lists.

What, however, I am specially anxious to do in this communication is to support and enforce the views of Mr. Giles with regard to "*cram.*"

I admire the impartiality with which he dealt out his trenchant criticism. It matters not where and *by whom* the evil is perpetrated: that it is growing, that increased facilities for its growth are daily being proffered, that the result is wholly vicious, that if not promptly checked it must go a long way to stultify and neutralize our efforts steadily yet intrinsically to raise the educational status of the body with which we are identified, are truths that can be substantiated by an overwhelming array of facts.

Such a condition of mental dyspepsia as now threatens rising pharmacy never has the world seen before.

It was my good fortune, in common with my brethren of the Conference of 1872, at Brighton, to listen to the able and emphatic denouncement by Dr. Attfield of the evils of "cram."

For aught I know to the contrary, he may have fully anticipated how severe would be the criticism with which his opinions would be attacked; scarcely, however, could he have imagined how swiftly and abundantly his prophecy would be translated into fact. All honour to his outspokenness.

The question now arises, how shall we, each one in his own quiet provincial sphere of labour, exercise a healthful influence on the young men around us? Just thus, I take it. By deprecating and doing our best to prevent youths who have made no preliminary effort from going to London, "entering" for a three months' "*grind,*" and then presenting themselves to the Examiners.

Further, let us stick to the serious advice to do steady persistent work at home. "No day without a line," is an old-fashioned maxim, but if ever it needed to be enforced 'tis now.

As I have already intimated, we are grateful that our sons have Bloomsbury Square or other schools of pharmacy to which to repair; but what we need to impress on them is, that a certain amount of preparatory labour is absolutely essential to utilize the benefit of such schools.

It is a matter of common notoriety that young men are going up to town lamentably ignorant of the very alphabet of technical knowledge.

If this were regarded merely as a phase of the educational controversy of the present day, my fears would soon be allayed, being but an incident in what by all thoughtful men is admitted to be a period of transition. But, sir, if we transfer our reflections from the teacher to the taught, from the machine to the product, what do we see but a perpetuation of that very ignorance and incompetency in the future, to remove which we have been perfecting such elaborate methods?

May "cram" soon be dead and buried, its epitaph engraved, and its very ghost denied a resurrection!

Ere closing this letter, the length of which, were it not for the importance of its subject matter, should have my apology, I must express the great satisfaction I feel that the views I have so long entertained, and on different occasions fully expressed, concerning the Preliminary examination, has recently received the avowed support of the Editor of the *Pharmaceutical Journal*, the President of the Pharmaceutical Conference, and now of Mr. Giles.

With the valuable support which such men render me by endorsing my views I am content to wait, assured it cannot be many years before the Pharmaceutical Society will transfer that examination to other bodies more competent than itself to conduct it.

S. R. Atkins.

Salisbury, October 13, 1874.

Sir,—The address delivered to the students in the Society's School of Pharmacy on Wednesday last will have been read with profound interest by all who have the elevation of pharmacy truly at heart. Never, perhaps, was the cause of sound and honest study *versus* cram more eloquently and effectually pleaded than in Mr. Giles's admirable address. The blow against cram has been struck with great force, and it now rests with the leading pharmacists in the whole country, and with the councils of provincial associations, to take care that the effect produced should be lasting. This cannot be done, however, without the hearty co-operation of every one interested in the higher education of pharmacists; for, unless the gist of Mr. Giles's remarks be repeated again and again whenever there is a suitable opportunity, it is to be feared that many of our young men will remain blind to their own interests, and, yielding to the temptations of cram, will continue in their unscrupulous attempts to defraud the examiners, the public, and, above all, themselves.

I cordially agree with Mr. Giles as to the ultimate necessity of the establishment of a compulsory curriculum of education as a condition of examination; but instead of viewing such a measure as an ultimate resource after all other means have failed, I believe the time for its serious consideration, if not for its early adoption, has come already. Much good has been done by the untiring efforts of the examiners, but examinations, however well conducted, cannot successfully stamp out the evil now existing without their being aided by, and conditional upon, an enforced curriculum of education. The subject appears to me to be fully ripe for discussion, and I trust that it will not again be allowed to drop without a full expression of public pharmaceutical opinion upon its merits.

Louis Siebold.

Manchester, October 14*th*, 1874.

Emplastrum Plumbi.

Sir,—In the *Pharmaceutical Journal* of 29th August I read a very interesting paper on "The official plasters, and improved formulæ for their preparation," by Mr. A. W. Gerrard, upon which a discussion ensued, and Mr. Umney introduced the subject of Emplastrum plumbi. The speakers who followed acknowledged the difficulty of procuring a good and uniform article, and I can readily understand that if the formula of the B. P. is followed, such a thing is impossible.

In the laboratory attached to the establishment in which I served my apprenticeship there was an Irish porter, who could neither read nor write, but whose *spécialité* was making Emplastrum plumbi, and I invariably noticed that towards the conclusion of the manufacture of a batch he managed to get rid of us from the laboratory for a few minutes. Subsequently I taxed him with adding something to the plaster, and he informed me what the additions were. I may mention that my then employer invariably refused orders from wholesale houses for his plaster, although he could have secured large ones, but he preferred restricting the sale to his own retail customers.

The quantities of litharge and oil used were as follows:—

Litharge in very fine powder . 20 pounds.
Best olive oil . . . . 28 ,, by weight.

Great care was used in selecting the litharge, which we *invariably powdered.* A large copper pan was used over a naked fire, but the pan was raised on iron rings, so that it did not rest on the fuel.

Gentle boiling was continued for ten to twelve hours, and from time to time water sparingly added. Experience taught us when the plaster was nearly finished, and then the addition of water was discontinued, and as much as possible of that liquid was then evaporated.

When we considered the boiling should cease, twelve ounces of the best yellow resin and two pounds of liquor potassæ were added, and dissolved and mixed, and the plaster allowed to stand all night.

Next morning, any liquid floating on the top of the hard mass was carefully removed and the plaster heated, several boys were told off for plaster pulling, and sufficient was poured into water to supply us. With our hands oiled we took about one pound each, and kept pulling and kneading it until the required colour and shortness (I use the word for want of a better) were obtained. Each one piled up his mass on the slab, while the Irish porter before referred to weighed off and rolled the lumps to their required length.

I do not justify the use of the resin and liquor potassæ, and I have no doubt many of my professional brethren will condemn it. I simply state that the result of making Emplastrum plumbi by the process I have named was the production of a plaster I have never seen equalled. It was adhesive without being sticky, and in my opinion realized what a plaster ought to be.

P. WELLS.

East Brixton, S.W., August 31st, 1874.

THE PRACTICAL CHEMISTRY EXAMINATION.

Sir,—Will you allow me, through your correspondence columns, to ask Professor Attfield and others whom it may interest, to turn to P. J., [ii.] vol. xi., p. 268, where it will be found that Mr. John Ingham, Junior Bell Scholar, formed the precedent which has been so honourably followed by Mr. Luff, for "in the laboratory class he obtained the full number of marks possible." Remembering what Dr. Attfield said at the opening meeting of the session, when reporting on his class (the report appears in last week's Journal), I think it but just to my friend and fellow-student to draw atention to this fact.

300, Holborn, W.C. JOHN MOSS.

Erratum.—In the list of subscriptions to the Benevolent Fund, on p. 274, l. 3, for "Oldham, Rigley, William, 10*s.* 6*d.*," *read,* "Oldham, Wrigley, William, 10*s.* 6*d.*"

"*Inquirer.*"—You will find recipes for making lemonade and similar drinks in most receipt books.

"*Mac.*"—(1) Possibly from all traces of chlorine, used in bleaching the paper, not having been removed. (2) It would be correctly described as a mixture.

J. Jarvis.—Your suggestion is not in accord with the usual practice, but it shall have our consideration.

"*Erin.*"—(1) See a note in vol. iii. of this series of the Journal, p. 821. (2) A description of a method of preparing iodized cotton, by heating iodine and cotton wool together in stoppered bottles, will be found in vol. ii., p. 245.

J. W. Yates.—No.

Sal Aeratus.—A correspondent writes as follows respecting this substance:—"In the Journal dated Sept. 26th, you say sodium bicarbonate and ammonium carbonate are both sold for sal aeratus. If you refer to page 1206, 'Wood's Dispensatory of the United States,' you will, under the a l / Potassæ. Bicarbonas, read as follows:—'Distillers and brewers may prepare this salt with great facility by suspending the alkaline solution (potassium carbonate) in a fermenting tun. The salt in powder called sal aeratus, made principally in New England, is, we believe, prepared in this way. In composition it is between a carbonate and bicarbonate.' In confirmation of this, I know a party who has for years sent to one of the North American States Potas. bicarb. pulv."

W. J. S.—"No licence is required for the sale of quinine wine, if made according to the recipe in the British Pharmacopœia, and not sold as a proprietary or patent medicine." (See *Pharm. Journ.* [3] vol. iii., p. 327.)

J. W. W.—See an article entitled "Australian Jottings," at p. 161 of the present volume.

J. Barnet.—There would be nothing to prevent you passing both examinations, if you are competent, before the date mentioned, provided that you are twenty-one years of age when you present yourself for the Minor. For particulars respecting the examinations, see the official announcements on the first leaf of this Journal.

J. H. Talbot.—No.

G. Dowman.—We do not remember the proceedings referred to, and have been unable to find any report of them. You are recommended to search the back numbers of the Journal.

"*Justitia Fiat.*"—The subject of your letter is not of sufficiently general interest to admit of its publication in this Journal. If you have suffered a pecuniary wrong, the best plan would be to seek redress through the authorized channels.

L. E. Bore.—(1) *Peplis Portula.* (2) *Koniga maritima* (3) *Scleranthus annuus.* (4) *Amaranthus retroflexus.*

L. A. R.—"Associates who have paid the current year's subscription" are entitled to vote. The voting papers will be sent out within a few days.

J. Beach.—Warm the marble portion, and partly fill the cavity with melted marine glue, then insert the handle.

C. J. C.—(1) There is a polyglot list in Dorvault's '*L'Officine.*' (2) Apply to Messrs. Reeve, Publishers, Henrietta Street, Covent Garden. (3) No.

H. S D.—Fuse the amber and add to it the linseed oil hot; boil until it strings well; then let it cool a little and add the oil of turpentine. It is difficult to prepare of a very pale colour, but may easily be bleached with some fresh-slaked lime (Cooley).

A Young Pharmacist.—This is not the first time that vague charges like those in your letter have been made; but whenever it has been possible to inquire into them, it has been found that they were based upon grounds which were either imaginary or fictitious. If the alleged practice referred to by you be so well known as you state, there could be no difficulty in demonstrating the evil and putting an end to it. We shall have no objection to assist you in that direction.

Dundee Chemists and the Edinburgh Price List.—A correspondent writes under the name "*Cæsar*" to ask why the Dundee Chemists do not stick to the Edinburgh Price List. He states that one of the principal chemists there "cuts keen, and dispenses prescriptions and sells sponges or Holloway's pills at a reduced rate to the members of the Dundee Professional Supply Association." Nevertheless, he believes that if the rest of the chemists were to rise in a body and strike for higher prices, they would in the end not lose anything, but be great gainers.

"*Caution.*"—Your question raises several points which could not be decided offhand or without an exact knowledge of the circumstances. You are recommended to send your question to the Registrar, accompanied by full details.

W. R. F.—(1) The "quantitative composition" of gunpowder is variable, according to the kind. In most cases, however, it approaches 74·9 of nitre, 11·8 of sulphur, and 13·3 of charcoal. For a comparative list see Watts's Dictionary of Chemistry, vol. ii., p. 957. (2) The sale of opium or a preparation of opium by an unregistered person is illegal. You are recommended to communicate with the Registrar in reference to the case mentioned.

"*Nemo.*"—We regret that we are unable to supply the required information.

W. G. Piper.—They may be obtained of Mr. Cutter, Naturalist, Great Russell Street, London.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Roberts, Mr. A. Lister, Messrs. Lescher, Sons, and Co., Messrs. Curtis, Mr. Symons, Mr. M. J. Bentley, Cæsar, Excelsior, Observer, Hampton, Theta.

MONOBROMATED CAMPHOR.*

BY M. GAULT.

Monobromated camphor, discovered by Swarts about the year 1862,† has been recently applied to therapeutics in France, by Dr. Bourneville, at the Hospice de la Salpêtrière.

The author having been called upon to prepare some, the only information on the subject at his disposition was that in Wurtz's 'Dictionary,' under the head "camphor"; at the time he had no knowledge of the more complete research of Maisch.‡ Wurtz describes two processes, the first of which, due to Perkin, consists in distilling, at the temperature of 264° C., bibromated camphor, which is formed readily in the cold; the crystalline substance obtained being purified by re-crystallization from alcohol. This method is not very practicable, even if it always gave the product sought; for besides the difficulties it presents, it occasions a considerable loss of the product. M. Wurtz preferred to operate with sealed tubes; but his experiments were purely speculative, and the process would be insufficient for therapeutic exigencies. It was from observations made while experimenting with the second process that the author was led to adopt what he considers to be an easy and uniform method of preparing monobromated camphor.

First, the author was induced to believe that the temperature indicated by Perkin, and afterwards by Maisch, was too high, and, further, that operation under pressure in closed vessels might be avoided. He therefore constructed an apparatus, which he describes, and conducted the operation under other conditions, by which he obtained a product that had undergone no decomposition, and resembled in purity that obtained in the previous experiments.

The operation may be divided into four stages: (1) Formation of bibromated camphor; (2) Reaction, giving rise to monobromated camphor, at a temperature below 100° C.; (3) Purification by washings and crystallizations; (4) Utilization of a secondary product (Swarts's hydrobromate of camphor bromide).

The formation of bibromated camphor ($C_{10}H_{16}OBr_2$) presents no difficulty; it is effected by the simple addition of bromine to camphor. Maisch uses a small quantity of alcohol, but this the author thinks unnecessary. The camphor, previously powdered, is introduced into a retort about ten times the capacity of the volume of bibromated camphor to be formed, and upon this powder the bromine is poured in a thin stream, with constant stirring, until the camphor is all liquefied; under these conditions approximately two molecules of bromine to one of camphor will be employed. The clearness of the reaction, which is indicated by the liquefaction, dispenses with the necessity of weighing, whilst a slight excess of one or other of the ingredients has not been found to influence the final product. The conversion of the bibromated camphor into monobromated camphor is effected in the same retort, to which is adapted a long and large abductor tube dipping into an alkaline solution; this has for its object the absorption of all inconvenient vapours. The retort is placed in a water bath, which is heated to ebullition. The reaction quickly manifests itself, and is accompanied by the disengagement of torrents of hydrobromic acid gas, and some vapours of undecomposed camphor and bromine. The dark brown liquid acquires an amber colour, and the evolution of gas slackens suddenly. The reaction, due to a very simple substitution, is represented by the formula—

$$C_{10}H_{16}OBr_2 = C_{10}H_{15}BrO + HBr.$$

The arrangement of the apparatus and the tumultuous disengagement of gas did not permit the author to recognize the exact temperature of the reaction; but he is certain that it commenced between 80° and 90° C., and did not reach 132° C. That temperature, therefore, mentioned by Maisch, he considers to be exaggerated. He insists upon attention to this latter point, because he is convinced, by comparison with other processes, that the quantity of oily product is thus notably diminished, and that the purification of the monobromated camphor is rendered more easy. The amber liquid which remains in the retort solidifies on cooling, and forms a friable and slightly citrine mass. If the contents of the retort be thrown into a capsule, the disengagement of hydrobromic acid continues during several hours, and the mass presents an energetic reaction. But if the same liquid be thrown into boiling distilled water, and the ebullition be continued some time in the open air, the hydrobromic acid gas is nearly entirely removed from the mass, and the last traces of bromine vapour by which it might be contaminated are driven off. The product is then nearly white.

In connection with this point the author remarks that the volatilization of monobromated camphor by the intervention of vapour of water, alluded to by Maisch, is not so notable as to counteract the advantage of this first stage of purification. To obtain the product colourless and crystalline, decolorization by animal black or repeated crystallizations may be adopted. In either case the citrine mass of crude monobromated camphor is treated with boiling 90° to 95° alcohol, and the filtered liquor left to crystallize. The author prefers the method of repeated crystallizations. The crystals are dried in the open air upon unsized paper.

The monobromated camphor so obtained consists of tufts of crystalline acicular colourless prisms with a rectangular base, which attain a length of three centimetres. The crystals are hard, and crackle between the teeth. They have an odour both of camphor and turpentine, less penetrating than camphor, but also less fugitive. Their slightly bitter taste resembles that of camphor or Venice turpentine.

Monobromated camphor is insoluble in water, and soluble in alcohol, fixed and volatile oils, ether, carbon, bisulphide, chloroform, etc. Its melting point, according to Maisch, is at 67° C.; according to Wurtz, between 76° and 77° C. The author found it to range between 69° and 70° C., solidification commencing below 69°. It boils at 274° C., with partial decomposition. Heated to 100° C., it should not give a sublimate of camphor; calcined with potash, it leaves as a residue a mixture of bromide and carbonate of potassium.

In the mother liquors, and upon the crystals of the second and third formation, is found the oily substance that has been before spoken of as Swarts's hydrobromate of camphor bromide; the utilization of this product forms the fourth stage of the operation. It might be almost entirely removed by pressing the crystals between filtering paper; but this method, besides being imperfect, would cause considerable loss. With the same object the author tried the action of alkalies, in the hope of fixing the

* *L'Union Pharmaceutique*, vol. xv., p. 266.
† *Jahresbericht*, 1862, p. 462.
‡ *Pharmaceutical Journal* [3], vol. iii., pp. 201 and 221.

hydrobromic acid of the compound, but the result did not answer his expectations. He prefers to follow the indications of Swarts, who recommends to effect the dissociation of the hydrobromate by a temperature of 260° C., according to the following equation:—

$$C_{10}H_{15}BrOHBr = C_{10}H_{15}BrO + HBr.$$

In order to avoid, however, the carbonization of a considerable portion of the product, the author operates at a temperature below 260° C., for between 200° and 220° C. the disengagement of hydrobromic acid is abundant, and the decomposition according to the equation is nearly complete.

The high temperature of 200° C. to 260° C. is thus only used by the author for the utilization of a secondary product, whilst in Perkin's process all the bibromated product is submitted directly to a temperature which decomposes a considerable proportion, and to a succeeding distillation, more injurious than useful. The oily body, after being heated to between 200° C. and 220° C., forms a black viscous mass, which upon cooling becomes solid and brittle. Treated with boiling alcohol this mass yields, after filtration, fresh colourless crystals of monobromated camphor. The author reports that, operating thus, he obtained about 250 grains of perfectly pure monobromated camphor in a single operation.

Physiological Action.—Dr. Bourneville has communicated to the Sociéte de Biologie the result of experiments made upon guinea-pigs, rabbits, and cats with this new medicament. He attributes to monobromated camphor the following physiological properties:—

(1.) It diminishes the number of beats of the heart and determines a contraction of the auricular vessels.

(2.) It diminishes the number of inspirations.

(3.) It lowers the temperature in a regular manner. In mortal cases this abatement augments until the death; when recovery takes place the lowering of the temperature is followed by a return to the initial degree, but this recovery requires a longer time than that occupied in the diminution.

(4.) It possesses incontestible hypnotic properties, and appears to act principally upon the cerebral system.

(5.) The system does not appear to become tolerant of this medicine, and its prolonged use—at least with guinea-pigs—brings on a rapid emaciation.

Dr. Bourneville therefore considers the use of monobromated camphor is indicated when it is desired to produce an energetic sedative effect upon the circulatory system, and especially upon the cerebro-spinal nervous system. It is one of the most clearly-defined anti-spasmodics.

Administration.—According to Dr. Bourneville,* monobromated camphor may be administered under the form of pills, with conserve of roses as an excipient, or in a mixture with mucilage of gum arabic and syrup. The dose for adults varies from twelve to about thirty centigrams daily. Dr. Bourneville uses pills containing each ten centigrams of monobromide, and of these he gives as many as twelve a day. When administration by the mouth is impracticable he employs the following solution in subcutaneous injection:—

Monobromated Camphor . . .	3 grains.
Alcohol	35 "
Glycerine	22 "

EMULSIO CARNIS.*

BY JAMES KEMBLE.

It has long been a question with me whether or no fresh raw beef could not be utilized as a medicine, and administered in a concentrated fluid form, where a strong nourishing diet is more needed than medicine. Seeing an article in the *Medical Times* on the administration of raw beef, I resolved to institute a series of experiments, to determine the possibilities of preparing a solution of it that would keep long enough without change to be of practical use. My experiments and their result were as follows:

Fresh raw beef (lean)	℥ii
Sweet almonds	ʒiv
Bitter almonds	ʒiii
Sugar	ʒii
Water sufficient for emulsion . .	f℥viii

I rubbed the almonds, beef, and sugar to a fine pulp in a wedge-wood mortar, then added water gradually until a smooth paste was formed, added more of the water and strained through a sieve, returned the mass to the mortar, and manipulated with the balance of the water until f℥vii of emulsion was obtained, strained through a fine strainer and bottled; this in my experiment I designate as No. 1 emulsion. I then mixed of

(2) No. 1 Emulsion, f℥xiv with Brandy . .	fʒii
(3) No. 1 Emulsion, f℥xiv with Sherry wine .	fʒii
(4) No. 1 Emulsion, f℥xiv with Glycerin . .	fʒii

Experiment No. 2:—

A. Fresh raw beef (lean)	℥ii
Sweet almonds (roasted)	ʒv
Bitter almonds	ʒii
Sugar	ʒii
Water sufficient for emulsion	f℥viii

Manipulated the same as No. 1, until an emulsion was obtained; it was mixed as follows:—

B. Emulsion No. 2, f℥xiv with Brandy . .	fʒii
C. Emulsion No. 2, ℥xiv with Sherry wine .	fʒii
D. Emulsion No. 2, ℥xiv with Glycerin . .	fʒii

I made the above divisions for the purpose of testing the preservative properties of each agent employed, with the following results:—

After twenty-four hours, all sweet and good.

After forty-eight hours—

No. 1. Emulsion fermented; unfit for use.
No. 2. Perfectly sweet.
No. 3. Faint odour; least bit sour.
No. 4. Sweet and good.
A. Emulsion No. 2, fermentation commenced.
B. Sweet and good.
C. A little sour, but no odour.
D. Sweet and good.

After seventy-two hours—

No. 2. Slightly sour, but without odour.
No. 3. Fermentation commenced, putrescent odour.
No. 4. Fermentation commenced, putrescent odour.
B. Good, but a slight sour taste left on the tongue.
C. No odour, but sour.
D. Sweet, good and palatable.

After ninety-six hours—

B. was unfit for use; fermented.
C. was sour; unfit for use; fermented.
D. was very slightly changed, still palatable.

It will thus be seen that the brandy and glycerin possess about equal preservative properties, although, in the latter case, the glycerin seems to preserve the greater length of time. The preference would seem to be in favour of roasting or charring the sweet almonds, as it destroys, to a considerable extent, the tendency of the emulsin to induce fermentation.

I then made another lot of emulsion, and tried it with ʒii of brandy and glycerin respectively, to f℥i of emulsion;

* From the *American Journal of Pharmacy* for October.

also with three grains of sulphite of calcium, sulphite of sodium and chloride of sodium respectively, to f℥i of emulsion ; the result was like experiment No. 2, with the glycerin and the brandy. The chloride of sodium mixture began to change in thirty-six hours (perhaps would not have done so if the proportion of salt had been larger). Sulphite of calcium and sulphite of sodium acted very similarly ; the emulsions showed no change for sixty hours, were fit for use for seventy-six hours, although change had commenced, but were unsightly, unpleasant mixtures ; while glycerin and brandy, or both combined, possess greater preservative properties, and make a pleasant, palatable mixture.

I then made some more of the emulsion, to ascertain *how much* beef could be incorporated in a pint emulsion, and found that eight ounces may be incorporated into it ; but for practical and economical purposes, six ounces is all that can be thoroughly exhausted of all soluble matter.

It will be seen, by the experiments here made, that raw beef is applicable to every-day practice in hospitals, cities, and places where there is access to the markets for the beef. Physicians can prescribe the dose to suit their patients, and it will have to be made fresh every three or four days during warm weather. My experiments were made in July, with the thermometer ranging among the nineties. I judge that in cold weather this preparation could be made to keep good and sweet for a week or more.

I would suggest a formula for general use, as follows, viz.:—

Fresh raw beef (lean)	℥vi
Sweet almonds, deprived of their shells and roasted	℥i
Bitter almonds	ʒvi
Sugar	ʒvi
Glycerin	℥ii
Water sufficient for emulsion	℈i

Rub or beat the beef, almonds, and sugar to a fine pulp in a wedge-wood or wooden mortar ; then add water gradually until a smooth emulsion is formed, and strain through a sieve or coarse cloth ; return the residuary mass to the mortar, manipulate with the balance of the water until f℥xiv are obtained, strain all through a finer strainer, add the glycerin, and bottle ; the bottle is to be kept well corked. Dose :—f℥i, containing ʒiii of the beef.

The physician in prescribing can order the addition of brandy, pepsin, or any other medicine he wishes to administer at the same time. I tried combining ferric pyrophosphate with the mixture ; it combines well, but makes a dark, unsightly preparation, on account of the combination of the iron with the blood contained in the beef.

Philadelphia, August, 1874.

THE KOUMIS CURE.

The following interesting information respecting koumis, the method of its preparation, and the koumis establishments at Samara, is taken from a description written on the spot by a correspondent of the *Daily News*. Samara is the capital of a comparatively new government, carved out of the neighbouring governments of Simbirsk, Saratov, and Orenburg, and situated on the left bank of the Volga, on the borders of Orenburg, on the high road to Asia.

"It has long been known that the Tartar tribes inhabiting what is generally known as Independent Tartary (no longer, however, since General Kaufmann's visit particularly independent) and the nomad tribes scattered over its northern frontiers, the Turkomans and the Kirghis, as well as other tribes more or less akin to these, such as the half-nomad Bashkirs of Orenburg, all used fermented mare's milk, which they call koumis, not only as a beverage, but as a substantial portion of their daily food. It was reported to combine the nourishing properties of milk with the invigorating qualities of alcohol ; indeed, among its other virtues it was said to exhilarate and to intoxicate. It came into the heads of some Russian medical men, of whom, I believe, Dr. Portnikoff, of Samara, to have been one of the first, that this koumis might possibly possess medical properties as well. It was observed that consumption and its cognate disorders were unknown among the tribes who habitually drank koumis. Starting from this observation, experiments were made on the *vilia corpora* of consumptive patients, and with highly beneficial results. Upon this Dr. Portnikoff started a koumis establishment at Samara. Its situation offered him many advantages. In the first place, from its position on the Volga, it was at least approachable, whereas Orenburg, the nearest spot where koumis could be said to be indigenous, was the *ultima thule* of the civilized world. This new establishment on the Volga was the means, therefore, of pushing the koumis outposts 300 miles westwards. In the next place, it was observed that the pasturage at Samara was similar to that at Orenburg. It is supposed that the virtue of koumis consists in a great measure in the rich quality of the mare's milk, which again is dependent, not only on the race of mares, but on the pasturage on which they are fed. All these are propositions which are more or less vehemently affirmed and denied by the different camps into which koumis connoisseurs are divided. For my own part, without giving any opinion on so profound a subject, I would only venture in a very general way to observe that it is a very old idol of the human mind to mistake accidents for essentials, and to argue that, because things have been invariably seen in conjunction, they must necessarily be connected as cause and effect. However this may be, the *haute école* of koumis connoisseurs maintain that koumis, to be efficacious, must not only be composed of the milk of thorough-bred Tartar mares, but of thorough-bred Tartar mares fed on the rich covil of the steppes.

"For covil (*Stipa pennata*) is the technical name of the grass which grows on the steppes, and which is the favourite food of the mares. It flowers prettily in a kind of white silvery wave for about a month at the beginning of June, and makes a not ungraceful ornament for the hair, especially of blondes. It is only the tender grass, not the flower, of the covil which the mares graze on. In the midst of the covil the *Absinthum tartaricum* grows abundantly, emitting the sweetest smell. I could not help fancying that the two must form part of the vaunted pasturage of the steppes. It smelt so sweet that I thought if I had been a Tartar mare I should certainly have made it a *bonne bouche*. I was glad to hear that my error had been shared by a learned German doctor, who writing *à priori* in his study in Livonia on the medical properties of absinth, suggests that as it is found in large quantities on the steppes where the Tartar mares graze, part, at any rate, of the virtue of koumis may be attributable to his favourite herb. It is to be hoped that the learned doctor's theory does not depend on his illustration, for it is, unfortunately, not founded on fact. The mares do not touch the absinth. The grass of the covil is their sole diet. The absinth, with its perfume, is there because the Tartar mare is an epicure, and she loves to regale one sense with the sweet odour of the absinth while the young blade of the covil ministers to another.

"The Tartar horse about whom all this fuss is made is the most insignificant-looking brute dignified with the name of horse I ever saw. He exactly corresponds to the pictures one has seen, and the descriptions one has read, of the nondescript animals upon which the Cossacks were mounted during the invasion of France in 1812. Small, shaggy, and impoverished-looking, he hasn't the devilry in his eye which distinguishes the little Shetland pony. It is only when he is in action that he gives you a taste of his quality. He then bristles up, buckles to his work, and you begin to perceive, when you have already been half a day's journey, the enduring qualities of the little animal you have been contemning. Many days' continuous travelling at the rate of 150 versts (100 miles) a day will give you some idea of his powers. Those who deny the indispensableness of covil will for the most part maintain that there is no saving grace in koumis proceeding from aught but the milk of thoroughbred Tartar mares.

"There are koumis establishments in Russia elsewhere than at Samara. At Czarsko Selo, in the neighbourhood of St. Petersburg, as well as in the Sokslniki environ of Moscow, there are similar establishments. At both these places, although the precious covil does not flourish, the Tartar-bred mare is alone in vogue. I visited both these establishments, but fell in love with neither. In the first place the neighbourhood of a capital (and both St. Petersburg and Moscow are capitals) is an unfavourable situs for a 'cure.' The contrast of a medical establishment with the surrounding associations is fatal to it. All such establishments have a melancholy and depressing look about them. Phthisis, catarrh, and tubercles seem written on every brick, and labelled on every bottle. I felt that I should have an attack of 'nerves' if I stayed there ten minutes, and that all the Tartar mares in Russia could not restore me. If you are unlucky enough to require a 'cure,' go bury yourself alive as far from the habitations of men as you can; flee from the very neighbourhood of a city, far more a capital. Consider that situation the best which offers you the fewest resources, otherwise your labour is likely to be in vain, and your "cure" a mockery and a delusion, All these advantages, I may mention, are pre-eminently secured at Samara.

"Besides these establishments at St. Petersburg and Moscow, Dr. Stahlberg, formerly at the head of the Moscow establishment, has set up a similar one at Wiesbaden, maintaining that the covil is all humbug, and that it is 'the breed that does it.' The sceptical analysis is carried still farther; for in London there is a Russian (Polish) medical man, Dr. Yagielski, an authority in koumis, who goes so far counter to the received notions on the subject as to deny not only the indispensableness of Tartar mares for the production of koumis, but even of mares at all, actually giving the preference (tell it not in Gath and whisper it not in Samara) to the domestic cow. But I must leave the cow-produced koumis to its fate, and proceed with my description of the genuine covil-fed Tartar-bred mare's milk, koumis. The process of manufacture is the following. I may mention that it is Bashkir girls who are generally employed to make it. It is their national beverage, and they best understand it. Being less wild, too, than the nomad Khirgis, it is easier to 'catch' this particular Tartar specimen.

"Koumis is fermented mare's milk. An element of fermentation is consequently required for its manufacture. This is supplied by koumis itself. A certain proportion (one-third) of koumis is poured together with (two-thirds of) fresh mare's milk into a clean wooden vessel resembling an ordinary English churn, and there left for from six to eighteen hours, according to the degree of (alcoholic) strength that is required. During this period it is from time to time subjected to a churning process, with the object of keeping up and stimulating the process of fermentation. Herein consists the chief art, and whatever secret there may be in koumis-making is to know the exact amount of churning required; for, although a certain amount is requisite, it must be suspended at the point where curds or butter would be formed. Habit and practice alone teach this to the koumis-maker. After this fermenting process, stimulated by the occasional churning, has lasted a certain time, say six hours, a portion of the contents of the churn is drawn off, and this constitutes the weakest kind of koumis, say koumis of the first degree of strength. The remainder in the churn is subjected to a further period of similar fermentation and churning, say for another six hours, and then the churn is again tapped, and koumis of the second degree of strength is the result. Then another period of say six hours of a similar process for what still remains in the churn, and this, when drawn off, constitutes koumis of the third degree of strength. It will be observed that the difference in the degree of strength of the koumis consists in the different amount of fermentation to which it has been subjected. The strength of the koumis ought to be graduated according to the requirements of different patients, and this is a matter of some importance in the case of invalids. As soon as the koumis is drawn off it is poured into ordinary quart bottles, made with extra strong necks, corked down, and tightly strung; for, containing as it does large quantities of carbonic acid gas, it is subjected to the explosive accidents of all such liquors. Indeed, the inexperienced koumis drinker, on opening a bottle of koumis for the first time, if he is lucky enough not to lose his eye by the explosion of the cork, will most undoubtedly be soused all over by the frothing liquid.

"I have mentioned that the koumis itself is the fermenting element used in the composition of koumis—one-third koumis for two-thirds fresh mare's milk. It may be asked, when koumis is not obtainable (as at the beginning of the koumis season), what substitute is used? A couple of table-spoonfuls of yeast are put into an ordinary-sized quart bottle, filled with mare's milk which is allowed to ferment for twenty-four hours. The contents of this bottle are then poured into double the quantity of fresh mare's milk, and allowed to ferment for twenty-four hours more. Then twice the amount of fresh mare's milk is again added, the whole fermenting for twenty-four hours more. Thus a sufficient amount of the fermenting element is obtained to begin operations, the proportion 1 : 3 being always maintained between the fermenting element and the fresh milk. Some patients drink as much as six or eight bottles of koumis a day. Some subsist entirely on it; but, generally speaking, people eat their ordinary meals, and drink koumis between. It has a sharp and bitter taste, caused by the lactic acid, which it contains in large quantities; and the strongest sorts of all leave a kind of soft buttery after-taste, which, however, the carbonic acid gas helps to dissipate. Some people never can get over their dislike to the taste of koumis, and those it is never likely to benefit. The complaints for which koumis is considered beneficial are consumption and, it may be said generally, all affections of the mucous membrane. It is, of course, a mistake to suppose koumis a specific for consumption. It is nothing of the kind. People sometimes go to Samara in the last stages of that desease, when neither koumis nor anything else can be of avail. But in the early stages of consumption it often effects, by its strengthening properties, a beneficial change in the organism of the patient, and helps to arrest the ravages of the complaint. Where, however, it is of sovereign efficacy is in cases of recovery from a long and wasting illness where no organic detriment exists. Often, in such cases, after a couple of months of koumis-drinking the system is braced up, the blood streams more quickly through the veins, the pulsation increases, and a general feeling of *bien-etre* pervades the whole man. Not that I feel inclined to attribute the whole benefit which is derived from a cure at Samara to the properties of koumis. The fine, dry, rarefied air of the steppes has undoubtedly something to do with it. The lungs are called into active play, and lend their assistance to the general recuperative process.

"You *feel* the dryness of the air at Samara. In the higher parts of the steppes there is no dew. The most delicate and consumptive patient can admire, with impunity, the beauties of the setting sun—and the sunsets are very beautiful at Samara. He is not obliged, as in Italy, to flee that treacherous hour: he can sit out of doors without risk, and watch that setting sun reflected on the Jigoulee hills which here skirt the Volga, fringing with gold the clouds that crown the summits of those glowing hills, and lighting up the whole expanse of the river with liquid glittering fire. There is no fixed duration for a "cure" at Samara. The average stay of patients is two months, but as koumis is rather a diet than a medicine, their stay is often prolonged beyond this period. The weather is the chief regulator in this respect. Fine hot weather is considered essential for a 'cure.' June, July, and August are the finest months. The koumis establishments, of which there are three principal and several smaller ones at Samara, are situated at distances varying from six to twelve versts (four to eight miles) from the town, and are composed not of single blocks of buildings, but of little detached houses, mostly built of wood, containing from two to six, and rarely as many as eight rooms each, the whole connected with, that is, surrounding, a larger building which is the kursaal of the little colony, or, where a kursaal does not exist, a central kitchen which ministers to the culinary requirements of the whole. When there is a kursaal, the patients can either dine there at a *table-d'hôte*, or separately in their own apartments.

"I have used the term 'colony' to describe these koumis establishments. It best depicts the effect which they produce on one at first sight. There, in the midst of the desert steppe, with few signs of human habitation around, you suddenly come upon a little wooden oasis, surrounded by a paling, and dotted about with a number of little single-storied wooden houses, resembling overgrown mushrooms, with zigzag walks or terraces cut in every direction, and queer-looking people, men and women, walking about—all drinkers at all watering-places are peripatetics—with a quart bottle in one hand and a large mug in the other, and you know that you are at a koumis establishment."

PECULIAR TOXIC ACTION EXERCISED BY THE COLCHICUM AUTUMNALE AT THE TIME OF FLOWERING.

BY I. PIERRE.

The author, in a letter recently communicated to the French Academy,* states, that having plucked some fully-expanded flowers of *Colchicum autumnale* in order to examine them more closely, he was surprised to notice that after a few seconds his fingers had changed colour, and taken the livid greenish yellow tint characteristic of a corpse in a state of incipient decomposition. After about ten seconds the skin regained its usual colour. As the discolouration extended throughout the length of the fingers, and even beyond, the question arose whether or not it was caused by absorption by contact at the extremity of the fingers. M. Pierre therefore extended his hand over a large clump of flowers, having anthers two or three centimetres in length, and carefully avoided all contact. The same phenomenon was produced with the same rapidity, and disappeared as quickly when the hand was removed. The experiment was repeated several times, and by different persons, but always with the same result.

In order to investigate the matter more conveniently, M. Pierre had two large clumps of the colchicum flowers placed in pots and removed to his laboratory; but on repeating the experiment twenty-four hours afterwards the effect was not so obvious. Upon comparing the flowers capable of producing the phenomenon with those which appeared to have lost the power, it was noticed that the inactive flowers had commenced to fade, and that the pistils and filaments of the stamens were much paler in colour than on the preceding day, or than those of less advanced flowers. He therefore thinks it presumable that it is principally during or approaching the act of fecundation that the colchicum flower possesses in the highest degree the property above described.

What, then, is the substance in the flower capable of producing this effect, which disappears so rapidly? The author thinks it can scarcely be a solid or a pulverulent pollinic matter, or the colour produced would be more persistent, but that it is probably an extremely volatile substance which has not yet been studied. In this view he is supported by the fact that after a number of experiments, without contact, and without raising his hand to his mouth, M. Pierre experienced in the organs of taste a peculiar sensation [*sensation vireuse*]; whilst his assistant, using the same finger many times, experienced a numbness in it which was persistent during several hours.

The author proposes to investigate the nature of this singular substance, which probably plays an important part in the accidents attributed to fresh colchicum compared with the innocuousness of the stale or dried flowers.

In connection with this action of certain principles of the colchicum flower, the author remarks that in the Gâtinais, where saffron is cultivated on a large scale, some persons, especially among women and children, cannot work at plucking the flowers without suffering from the symptoms of a peculiar poisoning, which manifests itself externally in a swollen and bloated appearance.

* *Comptes Rendus*, vol. lxxix., p. 633.

NOTES ON A NEW METHOD FOR THE ELECTRO-CHEMICAL MANIPULATION OF OILS AND OTHER NON-CONDUCTING LIQUIDS.*

BY W. SYMONS, F.C.S.

In following out some experiments, it occurred to me that the solutions of metallic salts in alcohol and ether may be made the medium of subjecting to the electric current various oils and other liquids which cannot be otherwise acted upon by the galvanic battery.

A solution of zinc chloride in alcohol, and ether shaken with liquor ferri perchlor. fort., P.B., suggested themselves. For the sake of brevity I will call the latter ferric ether, and this appears the best adapted for the purpose. In both these media oils, carbon disulphide, and other bodies may be brought under the influence of a weak galvanic current, and chemical changes in their constitution be thus produced. Carbon disulphide may also be mixed with oils in solution in ferric ether without destroying the conductibility of the liquid, and currents can be transmitted through such mixtures continuously for several days. Sometimes a body similar to camphor or spermaceti in appearance is formed at the cathode. Frequently the appearance of the liquid while in the circuit undergoes various changes during the course of the experiment, and sometimes, after a considerable time has passed, small bubbles of gas will be evolved on the one or the other electrode.

Convenient receptacles are small wide-mouthed bottles with corks, through which are passed, for electrodes, silver wires, sometimes with strips of platinum soldered to them. Iron wire has also been used for the anode and mercury for the cathode, but when mercury is used V tubes are more convenient than bottles. In other experiments with V tubes a solution of salt or lime has been used for the cathode. When lime water, or rather lime pulp, is used with carbon disulphide dissolved in ferric ether, the mixture seems to be gradually changed into carbo-sulphuret of calcium and the iron is precipitated, the denser liquid, which I take to be the carbo-sulphuret, gradually growing up into the ether, but with a well-defined separation between the two liquids.

Gas does not so frequently appear with ferric ether as when zinc-chloride and alcohol are used, and the zinc is much more readily deposited than the iron from the ether.

As far as tested by experiment, all oils soluble in alcohol are completely soluble in ferric ether, and all such solutions are conductors. Oils of cloves, pennyroyal, lavender, and cajeput have thus been tried, but not for any lengthened period. Castor oil has been kept longer under notice. When an iron wire is put into a mixture of castor oil and ferric ether, bubbles of hydrogen are generated even before it is brought into the circuit, and an iron and silver wire in this mixture will cause a deviation of the galvanometer, without the intervention of the battery. When carbon disulphide is added the gas no longer issues from the iron, but from the silver wire.

* Paper read before the British Association at Belfast, September, 1874.

Oils insoluble in alcohol, so far as tried, are only partially soluble in ferric ether. If five parts of lard oil, or cod liver oil, be shaken with seven parts of ferric ether, about three parts of the mixture is thrown down as a red liquid, which conducts the current, but the light portion of the liquid does not. If a current be kept up for some hours through the mixture by an iron anode and silver cathode, reaching to the bottom of the vessel, the red liquid will be gradually absorbed, losing its colour, and the iron wire will be enlarged by an accretion which I have not examined. Olive oil and colza oil throw down similar liquids, but of a light brown colour; and sperm oil agrees in colour with these vegetable oils rather than the animal oils before noticed. After being set aside for several weeks, the denser liquid in the olive and colza oil mixture was dissolved, the whole forming a brown, clear, homogeneous, conducting liquid.

From the cod liver oil mixture about two-thirds of the lighter liquid was removed and shaken with liquor ferri perchlor., without adding any more ether; it became a darker red than the precipitated portion. When not exposed to the air this red liquid remains unaltered, and as it contains iron in solution with cod liver oil, possibly the subject may have a significance and utility from a medical point of view.* This has led me to dwell more in detail on this experiment, but it will be obvious that a great number of combinations can thus be made the subject of investigation. I have, however, neither the time nor the appliances for fully carrying out the subject, and must be content with merely offering these hints, leaving it to more fortunate students of nature to follow it up. It is perhaps a bold assertion from one whose homespun apparatus and investigations are necessarily so imperfect and incomplete, but the behaviour of the ferric ether sometimes has led me to think that it acts the part of a conducting liquid diaphragm. Thus, when it holds in solution carbon disulphide alone, drops of a dense liquid gradually grow on a platinum cathode and drop off, which probably is carbon disulphide, thus transferred electro-mechanically, somewhat similar to the experiments recorded by Davy and A. Crosse.

In one experiment with lard oil and ferric ether carbon disulphide was added, which dissolved in the lighter liquid, thus bringing the specific gravity of the two layers of liquid nearly equal. On passing a current through wires reaching into the lower conducting liquid, small globules were observed to ascend by the side of the cathode and then to fall, thus keeping up a continuous circulation. Carbon monochloride has also been used, but only sparingly, as it is an expensive plaything, and its behaviour appears to be similar to carbon disulphide. It was attempted, without success, to dissolve some metallic chlorides in carbon monochloride. Platinum dichloride, left in this liquid for some weeks, softens into a liquid condition, but does not then conduct the current, which, however, was rather weak.

I have generally used forty pairs of the small battery which I will describe in another paper, but fifty or sixty pairs would have been better for some of the experiments, as, without using an iron anode, the deviation of the galvanometer was small, although quite distinct.

The galvanometer was also home-made, with twenty-four coils of fine copper wire. To the binding screws were soldered two short, stout, copper wires, amalgamated, and dipping into two mercury cups. A short, stout V of copper wire connected the cups. By removing this wire the current could be readily sent round the galvanometer.

The appearance in more than one experiment of a black powder on the surface of a mercurial cathode when carbon disulphide was in the mixture was at first an object of great interest. Might it not be an electric deposit of carbon? But as this powder dissolved in nitro-hydrochloric acid, it was probably mercuric sulphide. Although it may appear somewhat contradictory to some of Faraday's assertions in 'Experimental Researches,' series 7, etc., yet still there can be no doubt of the fact that in several of these experiments carbon disulphide was decomposed by the electric current; and seeing that A. Crosse, in his experiments, formed crystals of such bodies as silica and sulphur, is the thought necessarily a De Morgan paradox, to opine that even yet a way may be ultimately found to constrain coy carbon to congeal into concrete crystals?

Barnstaple, July 27, 1874.

* There was an allusion in a discussion in the recent Pharmaceutical Conference to the desirableness of having a solution of iron in cod liver oil.

OIL FROM NUX VOMICA.*

BY CHARLES BULLOCK.

In the preparation of extract of nux vomica, with the intention of having the extract sufficiently hard to permit of pulverization, the hardening process was conducted in a porcelain vessel heated by a steam jacket. As the extract solidified each night on cooling the oily matter rose to the surface, and was removed before reheating. From 150 pounds of nux vomica five pints of oil were obtained.

To ascertain whether this oil contained any notable portion of the alkaloids of nux vomica, four fluid ounces of the oil was agitated with water acidulated with sulphuric acid; the water was allowed to separate by long standing, and then removed. The process of washing was repeated as long as the washings were disturbed by a solution of caustic soda.

On the addition of the soda solution to a slight excess immediate precipitation occurred, the precipitate on stirring aggregated into a waxlike mass; at the end of twenty-fours hours the solution was filled with a copious gelatinous deposit. Both precipitates were collected on a filter, washed to remove the excess of alkali, and treated with water acidulated with sulphuric acid until exhausted. The acid solution was neutralized with soda, the alkaloids collected on a filter, dried and dissolved in hot dilute alcohol. The alcoholic solution yielded 10·6 grains of alkaloids.

The presence of strychnia was shown by the characteristic violet colour, when treated with sulphuric acid and chromate of potassium; but as the alkaloids dissolved *almost* completely in warm absolute alcohol, strychnia could only be present in small quantity, the major part being brucia.

The gelatinous matter when dry weighed 14 grains. Heated on platinum foil it remained unchanged, and was sparingly soluble in hydrochloric acid. When boiled with a solution of pure carbonate of potassium, and the filtered solution neutralized with nitric acid, the addition of nitrate of barium produced no change (absence of sulphuric and phosphoric acids). The insoluble portion remained insoluble in dilute hydrochloric acid; the precipitate was, therefore, not a salt of the alkaline earths.

A *second* portion was fused with pure caustic soda, the fused mass dissolved completely in water. To a part solution of chloride of ammonium was added, producing a copious flocculent precipitate, showing the base to be alumina. To the remaining portion of the soda solution, after super-saturation with nitric acid, solution of molybdate of ammonium was added, no reaction took place, even after long standing, showing the entire absence of phosphoric acid.

Prof. J. M. Maisch has noticed the presence of earthy phosphates in nux vomica [*Amer. Journ. Pharm.*, vol. 32, p. 524]. In this instance the phosphoric acid may have been removed by long digestion with dilute sulphuric acid and subsequent precipitation by soda.

The presence of alkaloids in the oil rendered apparent the suggestion of Prof. Procter, that, when the oil is removed, it should be agitated with a little dilute alcohol, which takes from it any adhering extractive matter.

RECENT FAILURES IN THE MINOR EXAMINATION.

THE subject of pharmaceutical examinations still continues to occupy the thoughts and fears of many who are in some way or other affected by the influence they exercise at the present time. We have recently received several letters in reference to this subject, and to the means of preparation for passing the examinations, which we have not published, since they appeared to have been written without due appreciation of the facts of the case. However, there are some points in these letters which it is desirable to refer to for the sake of correcting erroneous impressions which seem to be prevalent.

In the first place we select a letter written by Mr. SHILLCOCK, of Bromley, in which he expresses an opinion that some notice should be taken of the results of the present year's examinations, as contrasted with those of 1873. He points out that, according to statements he has obtained, the number of candidates for the Minor examination in 1873 was 745, of which number 410, or about 52 per cent., passed the examination; while in 1874 the number of candidates has been 894, of which only 278, or about 29 per cent., have passed. We do not stay to question the accuracy of these figures, nor do we entertain any doubt that they may be correct in the main, and, so far as the drift of our correspondent's letter is concerned, it may be admitted that the proportion of rejections in the Minor examination has been very much larger in the present year than it was last year.

Of course there must be, as our correspondent assumes, some particular reason for such a marked difference, and to this extent we may agree with him. But when he goes on to remark that this requires explanation because the Syllabus of 1874 was the same as that of 1873, we are unable to share his opinion. Still less are we able to concur with him in the extraordinary inference which he regards as being very clearly deducible from the facts he puts forward, viz., that in 1873 either a very great number of pupils were allowed to pass who were not competent, or a great number who were examined in 1874 were very unfairly dealt with. While giving Mr. SHILLCOCK all credit for the sincerity of his opinion, we cannot refrain from expressing our conviction that he has fallen into serious error, and the possible mischievous effects of such an erroneous opinion are sufficient to justify a more detailed refutation of it than some might think it to be deserving of.

Mr. SHILLCOCK declares that he cannot believe that in 1873 the standard of ability in the candidates was so much higher than in 1874, and adds that he does not hesitate to declare his conviction that the contrary was the case. In putting forward this view Mr. SHILLCOCK appears to have entirely forgotten the changes that have just come into force as regards the Minor examination. He strangely overlooks the fact that those changes—intended to give the examiners greater facilities for testing the practical qualifications of candidates—have been too commonly regarded as constituting an increased stringency in the Minor examination, and he omits to take into account that the natural consequence of such an apprehension—whether on real or imaginary grounds—would be to stimulate many towards endeavouring to pass the examination before the alterations came into force. So far back as the early part of this year such a tendency was recognizable, and in reviewing the general result of the examinations we took occasion to suggest the probability that, as the time approached for the new regulations to come into operation, a large number of candidates would enter the examination room prematurely.

The facts adduced by Mr. SHILLCOCK in regard to the proportion of rejections in the Minor Examination are to our apprehension ample proof of the justice of the anticipation we then ventured. The result of the fear that the examination would be in itself more severe has been manifest in the unusually large number of candidates presenting themselves. The equally unusual proportion of rejections has proved that very many of those candidates had not acquired such a knowledge of the subjects in which they were to undergo examination as to enable them to pass through this ordeal, or to qualify them for conducting the business of a chemist and druggist.

It is almost inconceivable that such a result as this should be to any considerable extent considered as a misfortune in regard to the general interests of the trade; but with regret we must recognize the fact that such an opinion does prevail. Even Mr. SHILLCOCK apologizes for bringing this subject forward by referring to the sentiments he has heard expressed, and by stating his belief that the great majority of chemists in the country would endorse the opinions he holds.

While we fully sympathize with those who have experienced the trouble, anxiety, and difficulty arising in many instances from the necessity to give proof of qualification, and from the inadequacy of the means by which such qualification can be obtained, we cannot allow regard for individual hardship to interfere with the consideration of what is imperatively demanded of chemists and druggists, not only in the interests of the public, but also for the attainment of the object for which the Pharmaceutical Society was founded and any attempt to obtain a Pharmacy Act was undertaken.

We intend noticing another phase of the subject next week.

LARCH BARK.

It appears possible that the introduction of Larch Bark into the British Pharmacopœia may be synchronous with the commencement of the disappearance of the Larch tree from Great Britain. Not, however, from an "ugly rush" of the public to try the new official remedy, similar to that which denuded the earliest eucalyptus plants in the South of France, but through a disease which is stated to be extending its ravages and increasing in malignity. Indeed, so convinced is a recent writer in the *Garden* that in this country the Larch and Spruce Fir are doomed, that he thinks the time has come for discussing the question by what trees they are to be replaced. It appears that this disease did not at first show itself in young trees, which were not attacked until they had reached the age of twenty, or even thirty, years. Now, however, trees still in the nursery are suffering from its ravages, and plantations of trees four and five years old are said to be dying off "wholesale." The present year would seem to have been particularly favourable to the propagation of this disease. The fact that it has been an unusually dry year, viewed in conjunction with various other circumstances, suggests the idea that drought has much to do with its origin. Both the Spruce Fir and the Larch, as well as the *Pinus excelsus*, all of which suffer from its attacks, come from more rainy countries than ours, and it is thought possible that, "owing to the system of excessive drainage which has, during the last sixty years, been carried to such an extent in this country (and more especially in Scotland, the focus of the disease), our climate has undergone such a change that those trees are unable to thrive in it."

"DISPENSING ALLIANCES."

The refining effects of the Chicago fire having been insufficient to purge the city of one bad practice, unfortunately too well known in this country, the scorching heat of newspaper criticism has been applied with somewhat better effect. On several recent occasions the medical profession of Chicago has been roundly charged by the *Chicago Times* with "collusion with pharmacists for the purpose of extorting money from their patients." This collusion was alleged to be evidenced by the use of prescription papers bearing the business "cards" of pharmacists; the occupation of offices, free or at a nominal rent, adjacent to, or belonging to, pharmacists; the writing of private formulæ, understood by certain pharmacists exclusively; and the acceptance of commissions upon prescriptions from pharmacists.

The effect of the attack, according to the *Pharmacist*, has been equal to a "ten strike," whatever that may mean. The Society of Physicians and Surgeons has held a meeting, and drawn up resolutions, in the preamble to which it was acknowledged that the practices above designated, although deprecated by many, always have been maintained by others, "innocently and in good faith, unsuspicious of their abusive application." The resolutions recognized, however, that such practices tend to the degradation and demoralization of the medical profession, and pledged the members to discontinue and discourage them. It was further agreed that the acceptance of commissions upon prescriptions by physicians from pharmacists is positively disreputable and dishonest, and should be deemed sufficient cause for the expulsion of a member from the Society. A committee was appointed also to consider, with a similar committee from the College of Pharmacy, what measures should be taken to check the growing evil of prescribing proprietary medicines, and the accepting of samples of such medicines from the agents of the wholesale drug houses.

A few days later the Chicago College of Pharmacy held a meeting, and passed resolutions recognizing the existence of the evil, condemning a system "that substitutes a money consideration for just claims of merit and education," and inviting the medical profession to aid the College in its endeavours to "emancipate the business from evils and abuses which prevent and hinder progress." A committee was appointed to co-operate with the committee from the medical society.

It was truly remarked in the Report to the Council from the Delegates to the International Conference that the effect of decisions in questions affecting pharmacy cannot be limited to localities, but that their influence for good or evil must be more widely felt. We therefore welcome this fresh blow at pharmaceutical palmistry and philippian prescriptions.

AN ADVANTAGE OF STATE EDUCATION.

According to the *Revue Internationale*, a decree of the Superior Tribunal of Jalisco, the capital of the province of Guadalaxara, in Mexico, enjoins all physicians and surgeons to give, without fee, their professional services to the tribunals whenever required. The Procureur Fiscal bases this demand upon the fact that, as the State gives medical instruction gratuitously, it has a right to the free services of those taught whenever it requires them. The reply on the part of the medical men is, that since education is given without charge in all the schools, it would follow that all the citizens should render their services upon the same patriotic terms.

POISONING OF CATTLE.

It is reported that twenty-three head of cattle have recently been poisoned in the district of Ballinrobe, co. Mayo, through grazing in pastures where an abundance of Meadow Saffron (*Colchicum autumnale*) was growing. When the mortality began to assume serious dimensions it was feared by the people living in the locality that it was due to some form of epizootic disease; but an investigation by an officer attached to the department charged with carrying out the provisions of the Contagious Cattle Disease Act revealed the true cause.

The Jalap plant (*Exogonium purga*) has flowered freely this season on a south wall at Kew. The *Garden* thinks that the beautiful appearance of its "rich purple salver-shaped flowers," independently of any other properties the plant may possess, render it well worthy of attention as a tender or half-hardy climber.

PRELIMINARY EXAMINATION.

The following is the result of the Preliminary Examination held on the 5th inst. :—

ENGLAND AND WALES.

Two hundred and twenty-two candidates presented themselves for examination, of whom *one hundred and thirty-two* failed. The following *ninety* passed, and have been duly registered as Apprentices or Students :—

- *Adams, Charles .... Birmingham.
- *Opie, Edward Augustus .... Plymouth.
- *Hart, Arthur .... London.
- *Mould, Arthur Howe .... London.
- *Walkley, James Byron .... Bollington.
- *Reade, Joseph George Edward London.
- Equal.
  - *Frost, George Percy H. .... Derby.
  - *Maddox, John Thomas Rowland Carmarthen.
- Morris, Thomas .... Denbigh.
- Equal.
  - Greener, Michael Hindmarsh ... Alnwick.
  - Hudson, George Mawdsley .... Southport.
- Watson, Henry Gervase .... Sheffield.
- Prosser, Francis .... Milford Haven.
- Williams, Egbert .... Coventry.
- Wheeley, John Thomas Martin London.
- Equal.
  - Cox, Ernest .... Bristol.
  - Harries, William .... Llandovery.
  - Pollitt, Joseph Moore .... Radcliffe.
- Equal.
  - Laing, Richard William .... Capetown, S. Africa.
  - Patterson, Thomas .... Preston.
  - Smith, Alexander Newsome ... Radford.
- Chambers, William Rubery ... Birmingham.
- Equal.
  - Baker, Charles Frederick .... Hitchin.
  - Fowler, George .... Tewkesbury.
- Equal.
  - Ground, Thomas .... Birmingham.
  - Groves, Arthur .... Cambridge.
  - Knott, Henry Archer .... Walthamstow.
- Davenport, George Harry .... Wolverhampton.
- Equal.
  - Evans, William Willoughby ... Cilsane.
  - Procter, John .... Pocklington.
- Holland, Henry .... Leftwich.
- Alcock, Henry .... Coventry.
- Equal.
  - Cass, Isaac .... Mirfield.
  - Gregory, Edward Thomas .... London.
- Equal.
  - Goodall, William Antony .... Bristol.
  - Richards, Thomas .... St. Clears.
  - Rossiter, Thomas Edward .... Tiverton.
- Dodd, William Ralph .... Market Drayton.
- Equal.
  - Armstrong, Benjamin, jun. ... Newcastle-on-Tyne.
  - Rogers, James Isaac .... North Shields.
- Equal.
  - Bevan, Edward .... Swansea.
  - Dixon, James Simpson .... Kendal.
- Crow, William .... Berwick-on-Tweed.
- Equal.
  - Coates, Frederick Charles .... Sudbury.
  - Hepworth, Arthur .... Newcastle-on-Tyne.
  - Morgan, William Henry .... Llanelly.
- Equal.
  - Hall, Thomas Wright .... Bristol.
  - Ward, William Wright .... Whitby.
- Jones, Richard Edward .... London.
- Equal.
  - Jackson, David .... Manchester.
  - Jones, Richard .... Swansea.
  - Metcalfe, John .... Bedale.
  - Middleton, Ernest Denny .... Marske-by-the-Sea.
  - Morris, Walter .... Farnworth.
  - Short, George William .... Swindon.
  - Wright, Edward Goddard .... Doncaster.
- Brown, Thomas Land .... Ripon.
- Equal.
  - Hebblethwaite, George Arthur Hull.
  - Robinson, Frederick Gardner ... Pendleton.
- Bridge, George Edward .... Maidstone.
- Equal.
  - Minnitt, Walter .... London.
  - Baker, George Henry .... Southsea.
  - Snell, Charles Henry .... York.
  - Williams, John Henry .... London.
- Woodman, John Dover .... Upper Norwood.
- Equal.
  - Beattey, William Crump .... London.
  - Burford, Samuel Francis .... Leicester.
  - Cattell, Charles .... Ely.
  - Clark, John .... Colne.
  - Cocks, Walter James .... Southsea.
  - Gravill, Edward Day .... Gainsborough.
  - Horrell, Alfred Charles Julian ... Dartford.
  - Jones, Thomas Slater .... Port Penrhyn.
  - Kelly, John George .... Leicester.
  - Loam, James Gilbert .... Kirkdale.
  - Manners, John .... Shildon.
  - Middlebrook, Joseph .... Sheffield Moor.
  - Newton, Henry .... Doncaster.
  - Nicholls, Samuel John .... Plymouth.
  - Parsons, Vincett James .... Icklesham.
  - Phillips, James Patt .... Bideford.
  - Roberts, Morgan .... Cardiff.
  - Rook, Barnard .... Sittingbourne.
  - Rundle, George .... London.
  - Shrivell, Frederick Wm. Edwd ... Hadlow.
  - Thompson, Hamilton .... York.
  - Vickerman, Thomas .... Nottingham.
  - Williamson, Edward Field .... Grimsby.
  - Windmill, William Henry .... Barking.
  - Woodrow, Walter .... Salisbury.

SCOTLAND.

Twenty-one candidates presented themselves for examination ; of these *twelve* failed. The following *nine* passed, and have been duly registered :—

- *Dick, George Walter .... Edinburgh.
- *Mackill, Robert Alexander .... Hamilton.
- *Eunson, John .... Kirkwall.
- *Glass, William .... Friockheim.
- *Duncan, William .... Leith.
- Ainslie, William Wood .... Edinburgh.
- Equal.
  - Donaldson, David .... Edinburgh.
  - Laing, Alexander .... Aberdeen.
- Kay, William .... Edinburgh.

The following is a list of the Centres at which the Examinations were held, showing the number of Candidates examined at each Centre, and the result.

* Passed in the First Division.

The questions for examination were as follows :—

Time allowed: Three hours.

LATIN.

N.B.—Candidates are not required to translate more than two paragraphs, and are recommended to select either Nos. 1 and 2 or Nos. 3 and 4.

1. Eo autem frumento, quod flumine Arare navibus subvexerat, propterea uti minus poterat, quod iter ab Arare Helvetii averterant, a quibus discedere nolebat. Diem ex die ducere Ædui, conferri, comportari, adesse dicere.

2. Multo denique die per exploratores Cæsar cognovit, et montem a suis teneri, et Helvetios castra movisse, et Considium timore perterritum, quod non vidisset, pro viso sibi renuntiâsse.

3. Necesse est, quæcunque in pulverem redigi præcepimus, ita per cribrum tenue demitti, ut separentur sordes et partes crassiores. Plerosque Pulveres oportet recens præparari, non diu servari.

4. Capiat æger haustum catharticum proximâ luce navem conscendens; et si post navigationem vomitus supervenerit, bibat æger spiritûs alicujus paululum aquâ commixtum.

5. Decline the pronouns Idem and Qui.

6. State the infinitive, perfect, and supine of the following verbs :—Juvo, edo, cubo, venio, doceo, coquo, mordeo, and spargo.

7. Parse "Ne multa discas, sed multum."

ARITHMETIC.

8. A gentleman's income is £896 13*s.* 4*d.* per annum; he gives to the poor £13 10*s.* quarterly, and lays up 200 guineas at the year's end; how much does he spend in six days?

9. If $\frac{3}{4}$ of a yard of cloth that is $2\frac{1}{4}$ yards wide will make a garment, how much cloth that is $\frac{7}{8}$ of a yard wide will make the same?

10. What is the value of a beam of timber whose length is 24 ft. 8 in., breadth 3 ft. 9 in., and thickness 2 ft., at 3*s.* $8\frac{3}{4}$*d.* per cubic foot?

11. State the equivalent in avoirdupois weights of a kilogramme and a litre respectively, and how many cubic centimetres are contained in a litre.

ENGLISH.

12. State the plurals of the following words :—Pony, grotto, valley, hero, scarf, genius, die, sheaf, index, and crisis.

13. Parse the following :—

Thou, whose almighty word
Chaos and darkness heard,
And took their flight,
Hear us.—

14. Write from fifteen to twenty-five lines on one only of the following subjects :—

Economy.
Painting.
Republicanism.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The sixth annual meeting was held at 37, Blackfriars Street, on Thursday evening, October 1, Mr. W. S. Brown, President, in the chair. The following report of the Council was read by Mr. F. Baden Benger, Hon. Secretary, and the Treasurer, Mr. Geo. S. Woolley, presented his statement of accounts, as follows :—

ANNUAL REPORT.

"The past year has been a somewhat uneventful one in pharmaceutical circles, but there is reason to hope that during this period the Manchester Chemists' Association has been more firmly established, and that its usefulness has not been less evident than in former years.

"The session was inaugurated on November 7 by a soirée and exhibition at the Memorial Hall. Upwards of thirty firms sent contributions, forming a collection of much interest. Several short lectures on scientific subjects were given during the evening. There was a large attendance, including some eminent members of the medical profession, and the meeting was a very pleasant one.

"In December Mr. Louis Siebold delivered an able lecture before the Association on the methods of detecting hydrocyanic acid and cyanide of potassium in cases of poisoning, and in January Mr. John Plant, F.G.S., very kindly contributed a lecture on Coal—its history and chemistry.

"During the session two evenings were devoted to conversation and discussion of a less formal character than usual. The experiment appeared satisfactory. There was a fair attendance, and several members brought forward subjects of interest to the Association.

"The reading-room and library have been open five evenings a week, except during the summer months; and, as before, students have been able to gain admission at any other hour by applying for the keys.

"Your Association is indebted to the Pharmaceutical Society for again contributing copies of the *Pharmaceutical Journal* weekly, and to the Pharmaceutical Conference for the annual 'Year Book.' A set of dried official indigenous plants has also been presented by Messrs. Butler and McCulloch.

"The numerical strength of the Association remains about the same as at the end of the last session. A large number of the chemists of the district are still unconnected with it, and as repeated applications have been made to all whose names appear in the Manchester Directory, the only inference to be drawn is, that they are unable to recognize the claims which we believe the Association has on their support. It should be borne in mind that, through the exertions of your Association, Manchester has become a centre of pharmaceutical education; thoughtful assistants, desirous of improving themselves, are anxious to settle in the neighbourhood, and parents are beginning to see the importance of apprenticing their sons in a locality where a means of acquiring professional as well as trading experience is afforded. It should be unnecessary to point out the substantial gain thus accruing to the whole body of the trade in this district, or to urge on business men so very evident a reason for maintaining the educational character of the Association.

"The income is at present insufficient to cover the charges for rent and taxes, water, gas, attendance, postage, etc., though every possible economy has been practised in conducting the business of the Association. Since its formation no paid assistance has been obtained, even for directing circulars, etc., as is usual in other large associations; and, though your council are most reluctant to curtail any of the advantages now offered to members and associates, or to propose a larger annual subscription, one of these courses seems likely to be forced upon them unless a larger number of members join our ranks.

"Your Council cannot refrain from an expression of regret that so few take an active part in promoting the success of the monthly and other meetings. Acceptable as are the subscriptions only of those who do not attend, it would be a great encouragement to gentlemen who devote much time and trouble to the preparation of lectures and addresses if these gatherings were more truly representative of the trade of the district. It is satisfactory, however, to notice the large number of associates always present, and your Council are aware that in many cases principals are compelled to stay at home in order to give their *employés* the opportunity of attending.

"The School of Pharmacy in connection with your Association is now recognized as one of the legitimate pharmaceutical schools of the kingdom, and judged either by the quality of the teaching or by the number of students, will bear favourable comparison with most others. A detailed report of the School for the last session has been already published. The entries for the chemistry course were 21, for the materia medica course 19, and for the botany course 23. In these subjects no fewer than eighty lectures were delivered by Mr. Siebold. The fees formed that gentleman's very inadequate remuneration. These courses will be repeated during the ensuing session. Mr. Siebold will again undertake the chemistry and materia medica courses, whilst the services of Mr. Leo H. Grindon, well known as a lecturer on botany, have been secured in that department. A course of practical laboratory instruction is also arranged, under the direction of Mr. Siebold.

"Your Council have much pleasure in announcing that Mr. Siebold has undertaken to deliver, gratuitously, a short course of lectures during the winter, on 'The Analysis of Common Articles of Food,' to which members and associates will be admitted free.

"During the six years since its formation no extraneous assistance has been asked by the Association. It is for the incoming Council to decide whether, considering that the sum of upwards of £550, including lecture fees, has been expended, and a further sum of £60 devoted to the formation of a library, the time has not arrived when the Pharmaceutical Council should be asked for some aid in carrying on future work.

"Your Council would, in conclusion, again most earnestly urge on all members of the trade the duty of assisting in securing the permanent establishment and extension of our educational arrangements, fully believing that it is the interest of all to co-operate in so important an undertaking."

THE TREASURER IN ACCOUNT WITH THE MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION, OCTOBER 1, 1874.

Examined and found correct,

C. A. JOHNSTONE.
STANDEN PAINE.

The Report and Treasurer's Statement were adopted, and the usual votes of thanks to the returning officers having been passed, the following gentlemen were re-elected office bearers for the ensuing year:—President, Mr. W. Scott Brown; Vice-Presidents, Mr. J. T. Slugg, F.R.A.S., and Mr. W. Wilkinson; Treasurer, Mr. Geo. S. Woolley; Hon. Secretary, Mr. F. Baden Benger. Council: Messrs. Barnaby, Blain, Bostock, Botham, Hargraves, Hughes, Kay, Mumbray, Payne, Robinson, Hermann Woolley, and J. Waterhouse. Messrs. C. A. Johnstone and Standen Paine were re-appointed Auditors.

The members afterwards dined together at the Blackfriars Hotel. Amongst the visitors were Mr. John Plant, F.G.S., Curator of the Peel Park Museum; Mr. Estcourt, F.C.S., City Analyst; Dr. Edwards, and others.

Some excellent speeches were delivered, and a most agreeable evening was spent.

LEEDS CHEMISTS' ASSOCIATION.

The 12th annual meeting was held in the library on Wednesday afternoon, October 14, 1874, the President, Mr. F. Reynolds, in the chair. The minutes of the last meeting having been read and confirmed, the Secretary (Mr. J. W. Longley) read the

REPORT.

"Numerically, the last session has been a successful one. The increase in the number of members is four over last year, and the increase of associates is nine over last year, making an increase in the annual subscriptions of £3 2*s*. 6*d*. Your Committee have pleasure in stating that there is at present a balance in favour of the Society of £9 1*s*. 6*d*. The expenses during the past year have been somewhat heavy. A room in the Philosophical Hall has been engaged for two of our monthly meetings, and many minor expenses have tended to lessen the balance in hand. Your Committee have pleasure in drawing attention to the new library, and trust that the comfort of the room, the additional books, and various advantages that are now offered will materially increase the attendance at all lectures and meetings. The first monthly meeting was occupied by a social gathering at the Trevelyan Hotel, on November 12, 1873, when the members and associates, together with the chemists and druggists of the town, assembled to the number of nearly 100. Tea and coffee were provided at 8 o'clock in the evening, the president, Mr. Reynolds, in the chair. After a very excellent address from the president, a paper was read by Mr. R. H. Davis, of Harrogate, on 'The Monthly Analytical Examinations of the Harrogate Spas, 1872.' During the past session papers have been read as follows:—'Fermentation,' by Mr. Louis Siebold, Manchester; 'Water,' by Mr. E. Brown, Leeds; 'The Roots and Stems of the British Pharmacopœia,' by Mr. James Abbott; 'The Adulteration Act,' by Mr. E. Yewdall. Your committee take this opportunity of thanking those members of the Association who have assisted them in this work.

"Two members of the Association attended the British Pharmaceutical Conference, held in London during the month of August last, as delegates from our Society.

"The following books have been added to the library:—'Thorpe's Quantitative Analysis,' 'Armstrong on Organic Chemistry,' and 'The Year Book of Pharmacy,' a donation from the Committee of the Pharmaceutical Conference.

"A class has been conducted by Mr. J. Abbott during the past session, on Materia Medica, and has been attended by 17 students from our Society. Two prizes were offered, the first a book value 15*s*., the second a book value 7*s*. 6*d*. Mr. Hanbury was asked to adjudicate on the papers, and kindly consented. Only four candidates presented themselves for examination. None of the candidates having arrived at Mr. Hanbury's standard of merit, your committee regret that they could not conscientiously award a prize to any of the students.

"A class has been conducted by Mr. George Ward during the past session, on Inorganic and Organic Chemistry, and has been well attended by the chemists' assistants and apprentices in the town. The following is the result of the examination held at the conclusion of the course, under the Science and Art Department, so far as our associates are concerned:—

"*Inorganic Chemistry.*—Mr. E. O. Brown, elementary grade, first class, and laboratory practice; Mr. J. Fisher, elementary grade, second class.

"*Organic Chemistry.*—Mr. A. A. Pearson, advanced grade, second class, and laboratory practice.

"Two prizes were offered by the committee, value the same amount as those for the materia medica students; Dr. Attfield adjudicated. Only two candidates presented themselves; the first prize was given to Mr. E. O. Brown, and the second to Mr. C. A. Smith.

"The following is the treasurer's account for the past year:—

Dr.

JOHN BOWMAN, } Auditors.
T. B. STEAD, }

"Your Committee have pleasure in stating that the Chemistry Class, conducted by Mr. Ward, and the Botany Class, conducted by Mr. Abbott, will be carried on during the coming session, particulars of which have been forwarded to each member and associate. Your Committee cannot but feel that the numerical strength of the Society is weak, compared to the number of chemists' assistants and apprentices in the town, and also regret that the attendance at meetings and lectures is of so limited a nature; they would therefore suggest that each member and associate should do his utmost to point out to his friends the desirability of upholding the society by attending lectures, &c., so that not only is their own knowledge increased, but the interests of the trade are better promoted, and the feeling of good fellowship more firmly established."

On the motion of Mr. Brown, seconded by Mr. Taylor, the Report was adopted.

The election of officers for the coming session was then proceeded with, and resulted as follows:—President, Mr. Freshfield Reynolds; Vice-President, Mr. Edwin Yewdall; Honorary Secretary, Mr. Samuel Taylor; Librarian, Mr. E. O. Brown; Curator, Mr. Payne; Committee, Messrs. E. Brown, George Ward, William Smeeton, John William Longley, R. Simpson, and P. Jefferson.

Mr. F. Reynolds then moved that a vote of thanks be given to the retiring officers, and spoke in praise of the manner in which Mr. Longley had fulfilled his duties as honorary secretary. Mr. E. Brown said he could fully endorse the remarks of the president. The motion was seconded by Mr. Yewdall, and carried.

It was then resolved that two prize books should be given at the end of the course to the two students from the Association who have attended Mr. Ward's class, and attained the most proficiency, the first to be a book, value not exceeding 14*s.*, and the second not exceeding 7*s.*

Mr. Brown offered to give a book, value 6*s.*, for the second best student in the Materia Medica Class, Mr. Richard Reynolds having offered to give a book as first prize at the last meeting.

GLASGOW CHEMISTS' ASSOCIATION.

ASSISTANTS' SECTION.

The opening meeting of session 1874-5 was held in the West Hall, Anderson's University, on Wednesday, October 14, at nine p.m., the president, Mr. John C. Hunter, in the chair. There was a good attendance of members. The meeting being constituted, twelve new members were elected. The president then delivered an opening address, in which, after recounting the principal events in the history of the Association during the past year, he turned his attention to the History of the Microscope. The following is the substance:—

Mr. Hunter commenced with a short epitome of the papers read by the members of the junior section of the Association last session. Mr. Foster had read a very interesting and instructive paper on the Animal Substances used in Medicine, more especially dwelling upon those contained in the B.P., and referred the various substances to their natural orders and classes. A very good paper on the Manufacture of Iodine had been read by Mr. Currie, who exhibited a series of well-executed drawings of the various apparatus used in its manufacture, and concluded his paper by showing the various tests for the recognition of iodine. The third paper was read by Mr. Murdoch, the late secretary, and entitled "Drugs and Druggists," in which he described some of the disadvantages of chemists and druggists, more especially regretting the late hours they were subjected to in discharging their duties to the public, and adverting to the small modicum of thanks they sometimes got in return. A paper was read by Mr. Bray, on Mercury and Its Preparations. He described the extraction of mercury from its ores, and its combinations with oxygen, chlorine, the red oxide, and the two chlorides. He also referred to the preparation of the ointment, blue pill, and mercury with chalk. Mr. Hunter himself had read a paper on the modern relations between Organic and Inorganic Chemistry, in which he endeavoured to show that the barrier that once did separate them no longer exists, and that some substances can be produced by artificial means which formerly were supposed to require the vital action of plants and animals.

After this summary, Mr. Hunter read his paper on the History of the Microscope:—

"In ancient records some mention occurs of lenses being used for the purpose of making bodies appear larger than they seemed to be to the naked eye. Seneca, who lived about the beginning of the Christian era, alludes to them, and Pliny also mentions the magnifying and burning power of lenses. From the time of Pliny up to the fifteenth century, however, there has been no record found of any instrument similar to that now called the microscope.

"The Italians and Dutch have disputed as to the priority of the invention of the microscope, but the names of the rival claimants have been lost to us, so that it is very difficult to say to which of those countries the honour belongs. The first mention of its construction is about the year 1590, when an ingenious Dutchman, Zacharias Jansen, and his son, were among the first to make them. A short time afterwards we find one named Cornelius Drebbel made and brought over to England a microscope. Drebbel's microscope was a good deal larger than those now employed; it was more like what is now called a telescope, being about six feet long and one inch in diameter.

"Fontana, in a work published in the year 1646, says that he had constructed a microscope in the year 1618, or about 28 years after the Jansens are said to have made one. In the year 1685, Stelluti published a description of the various parts of a bee, which he had examined with a microscope. These microscopes were what are now called simple microscopes, because composed of one lens only, and they were similar in structure to those that are sometimes vended in the streets by peripatetic merchants for a few pence. Yet, by means of the simple microscope, very many great discoveries were made by acute and enthusiastic observers. About 1665 two names began to appear which will be handed down to posterity connected with discoveries made with the microscope, namely, Leeuwenhoek and Hartsoeker. It is to Leeuwenhoek, however, that we are most indebted for some of the most wonderful discoveries ever made by the instrument. He used to live a very solitary life, shutting himself up in his study to watch the various phenomena connected with the inhabitants of a world not visible to the eye alone, and after observing their motion, etc., he wrote descriptions of them that quite astonished the world at that time. Leeuwenhoek made all his own lenses, and at his death he left some of them to the Royal Society of London.

"Hartsoeker, together with Dr. Hooke, was the first to introduce glass globes for magnifying instead of a convex lens. On account of their sphericity they magnified bodies enormously, and by their means it became possible to see the animalcules in water impregnated with vegetable remains.

"In the year 1740, Dr. Lieberkuhn greatly improved the simple microscope, and, like Leuwenhoc, he made his own, using one microscope for examining one or two objects only. On that account he was continually making new ones, twelve of which he left at his death to the Royal College of Surgeons of London. Lieberkuhn was also the inventor of the solar microscope.

"The first three compound microscopes were invented by Dr. Hooke, Eustachio Divini, and Philip Bonnani. Dr. Hooke, in a preface to his 'Micrographica,' published in the year 1767, gives an account of his compound microscope; its length was about 7 inches, and it was composed of one object glass, one mid-glass, and one eyepiece. Eustachio Divini published an account of his in the year 1768. It was composed of one object-glass, one mid-glass, and two eyepieces; its length was about three feet when drawn out and sixteen inches when shut up, and its greatest magnifying power was about 143 diameters. Philip Bonnani's microscope was closely allied to Dr. Hooke's, being composed, like his, of one object-glass, one mid-glass, and one eyepiece. Sir Isaac Newton, after his famous discovery of the composition of white light, made experiments with various kinds of lenses, to obviate the chromatism or coloured fringe that surrounded the image of any body viewed through a refracting lens. But it is not to Sir Isaac Newton that we are indebted for the invention of the true achromatic microscope, although he was confident that it would be ultimately accomplished. Euler, in the year 1776, was the first to invent a near approach to the achromatic microscope, and in the year 1816, Fraeunhofer, the celebrated optician of Munich, well known for his discovery of what are called 'Fraeunhofer's lines' in the Solar Spectrum, improved upon the microscope of Euler; but still it was not truly achromatic. In the years 1823-4-5, the Academy of Sciences, Paris, and the Royal Society of London were presented with microscopes truly achromatic, and from that time till now there has been a gradual progression in their manufacture, both as regards lenses, stands, condensers, etc. Microscopes may now be purchased for from a few shillings to over one hundred pounds, and the magnifying power varies from 20 diameters to the enlargement of surface 56,000,000 times."

Mr. Hunter then gave an interesting sketch of some of the various ways in which the microscope is utilized in scientific investigation.

At the conclusion of the reading of the paper the President was awarded a hearty vote of thanks for his excellent address, and his kindness in again accepting the presidentship.

The Secretary (Mr. John Foster) intimated that a tutorial class would be formed, to assist young men in preparing for the preliminary examination, should a sufficient number come forward. At the close of the meeting 15 gentlemen enrolled themselves for the same.

A letter was read from a gentleman, complaining that some neighbouring chemists had failed to persevere in the early closing movement. Messrs. Murdoch and Hunter were elected a deputation to investigate the matter.

The following donations were made to the library:—From Mr. R. S. Neilson, 'Green's Botanical Dictionary,' 2 vols., and 'Spon's Workshop Receipts;' from Mr. John C. Hunter, President, a second donation of microscopic objects.

It was intimated that the next meeting would be held on Wednesday, the 11th of November, when Mr. William Currie would read a paper on 'Bleaching.'

BRISTOL PHARMACEUTICAL ASSOCIATION.

The first general meeting of the present session was held at the Bristol Institution, on Friday, October 16.

The president, Mr. G. F. Schacht, in introducing the proceedings, said his first duty that evening was an extremely agreeable one; it was to announce to the members that the President of the Pharmaceutical Society of Great Britain honoured them with his presence that evening. Mr. Hill's interest in the work they were engaged in promoting had been, as they would well remember, most substantially shown. It was only on the occasion of their last gathering that he had had the pleasure of making known to them the nature of that manifestation; and he was sure they would agree with him that his presence there that evening was another proof of the sincere interest he felt in their work. In their name, therefore, as well as his own, he rejoiced to offer him a hearty welcome, and thank him very much for having come amongst them. He had also to announce, on behalf of the Council, that they had succeeded in getting an excellent programme of monthly evening lectures, lacking in no respect the interest they had possessed on former occasions. Some old friends, and a few new ones, had been good enough to promise their help; and really, in making that announcement, he could not help congratulating the Society on the many kind friends they had, who assisted them in the most generous manner in the work they had undertaken. He was sure they were very grateful to them, and fully appreciated the value and importance of their co-operation. He would also remind them, though probably they had all seen the notices, of the courses of lectures which had been arranged on chemistry and botany, and which would be under the direction, as heretofore, of their kind friends, Mr. Coomber and Mr. Leipner. In connection with these classes, the Council had determined to offer again something like the same system of prizes as had been offered last year to those young men who would enter into the matter of their own education cordially, and show their appreciation of the efforts made to supply the means by presenting themselves at the examinations. There would be also some prizes given for an examination on the chemistry, botany, materia medica, and pharmacy of the Pharmacopœia. That was a somewhat alarming title to give it, but, on reflection, it would be found not so formidable after all. The examination would take place some time after the conclusion of the session, and the prizes would be provided out of the fund which Mr. Hills had given. The object of the Council in offering these special prizes was to induce and encourage a practical study of pharmacy, and the sciences surrounding it, in their everyday work. That really would be what the examination would test, and he hoped a large number of his young friends would compete when the time came. The details were not yet quite settled, but they would be announced in due course. Another subject to which he must allude was, that in the autumn of next year the British Association would probably meet in that city, and they would remember that the Pharmaceutical Conference held its gathering simultaneously with the greater gathering. On previous occasions very interesting papers had been read by gentle men residing in the towns in which the meetings had been held. He might say that some of the most important communications he had heard read before the Conference had been from members residing in the special locality in which the gathering had been held; and he took that opportunity of most urgently drawing their attention to the fact, in the hope that the Bristol Association would be really well represented on that occasion, and that they would, one and all, endeavour to uphold, to the utmost of their ability, the dignity and reputation of the pharmacy of the West. There was only one hint he would give, and that was, that any gentleman intending to prepare a paper for the occasion should begin as early as he possibly could, so that he might not suffer the grief and annoyance of finding he had not perfectly completed his work when the time arrived. It was right that he should now thank them for having called him once more to the duty of being their president. As one of them, he was only anxious to take his turn in such matters, and, of course, he willingly acceded to the request made to him. It was in accordance with their usual habit to elect to the office the same individual two years in succession. The plan had its recommendations, but it had also its disadvantages, one of them being that the same person was expected to prepare two consecutive addresses, which should possess some degree of interest. But one must accept the duties as well as the honours of a position. On the last occasion he was anxious to direct his observations more particularly to their younger members, and that was one reason, perhaps, why he should not do so a second time. Another and a more important reason was, that from a much larger platform — namely, the Lecture Hall of the Pharmaceutical Society of Great Britain—the great bulk of pharmaceutical students had been recently addressed most ably and most thoughtfully by their fellow-member, Mr. Giles; and it would be simple tautology if he were to attempt to go over the same ground again. He sincerely hoped they had all read that address, but if any had not he recommended them to do so on the first opportunity. These circumstances had constrained him to endeavour that his remarks on the present occasion should possess a somewhat more general interest; and he would now, with their kind permission, proceed to read them.

The President's Address.

"There is a word familiar to us all which has somewhat recently received a legal definition. The law defines a "chemist and druggist" to be a person entitled to keep open shop for the sale and dispensing of poisons. From this point of view the occupation of a chemist and druggist is emphatically a trade; but his duties neither begin nor end with, though they may include, the keeping a shop and the selling of poisons, for he has also to practise pharmacy.

"Pharmacy is an art—a branch of the great and blessed art of healing—and for its proper practice there are two requirements, over and above all that concern simple trading, namely, a scientific training and a knowledge of scientific matter.

"I have thought that these relations of the several portions of our duties are not quite always sufficiently kept in view, and that perhaps it might be useful to-night to speak of pharmacy in its relation to the art of medicine —its ultimate dependence, in common with all the other branches of that art, upon scientific knowledge —and the position of the chemist and druggist to the whole matter. Grant me leave, however, to indulge in a few abstract considerations first.

"Science may perhaps be broadly defined as man's intellectual effort to apprehend the phenomena of the universe. As nature is probably one, so science may be assumed to be one likewise; but, from the contracted and limited nature of man's time and powers, it has, during the processes of his work, and in the expression of that work, become divided into many sections.

"An art is (or perhaps I should rather say ought to be) a practical application of scientific principles to some useful purpose, and were the knowledge of those principles complete the art might be perfect. But no department of knowledge since the world began has ever been so exhausted of its treasures that man has been able to close the account and say—this is complete. On the contrary, that which was so grandly true when first uttered is equally true now, and probably will ever be true as long as we continue man; what we know is but as the pebble compared with the illimitable ocean of truth; and as the pebbles of our own material shores are cast about hither and thither by every tide and wave of the giant sea, causing sandbanks to shift, beaches to rise, and the whole face of the coast to change, so, with each fresh tide of discovery the face of science may become absolutely changed, and the old landmarks of knowledge valueless and waste. Everything outside and inside of man is apprehended by him simply as his nature enables him to apprehend—that is, partially and incompletely; and hence his most elaborate summings-up and views of knowledge are of necessity transitional, and change (ever, let us hope, to something larger and truer) becomes the very first condition of mental activity.

"The period of our own times appears to be crowded with illustrations of this truth; and were I able, even in a very loose manner, to epitomize the masses of work and of thought that have enriched the fields of science during recent years, you would be willing to join in almost any expression I might suggest of wonder and delight. But the slightest of all glances will suffice to show, not only the immense activity and energy that have been enlisted in the work, but also the many diverse aspects some of these sections of science have been made to assume under the differing intellectual atmospheres through which they have been viewed. Let us try and take that glance together.

"If it be directed to the region of physical science, the first point to arrest our attention will probably be the grand generalization known by the expression—the conservation of force, through which all phenomena attended with disturbance of force are regarded as correlated with each other—every single manifestation being in essence the transmutation of one form of force into another—each being the precise measure of the other—all being capable of exact expression in one common language—nothing being lost. Thanks to the secure method of modern inquiry, this generalization is the result not of conjecture, but of close reasoning upon evidence, that evidence being laborious experiment.

"There must be many among you able as I am to remember when this idea was but dimly shadowed forth; and when, on the contrary, we were more commonly taught to regard light as an "emission," heat as a substance called "caloric," electricity as a "subtle fluid," and chemical action as the result of an "affinity." Moreover, a peculiar severance was insisted upon between all these and mechanical motion, which was deemed to have neither resemblance nor relation to any amongst them.

"But what a chasm between these two sets of ideas! It is sometimes said time should not be measured by days and minutes, but by the tides of emotion that sweep through us. By such a record what ages seem here to intervene. The steps seem almost infinite in number, and as one's thought endeavours to rest for a moment upon some that appear more marked than others—such, for instance, as are suggested by the words Electrolysis, Vapour-densities, Specific heats—we find it difficult to realize that so vast a region could have been explored within the short period of one's own day.

"Side by side with this struggle to apprehend the nature and attributes of *force*, there has been an equally anxious effort to attain to a knowledge of the ultimate condition of matter.

"It is not to be wondered at that those familiar to some extent with the properties of masses of matter should set themselves to inquire of what those masses consisted, nor is it surprising that when all proximate and tangible processes of analysis had been appealed to in vain, imagination and speculation should have sought to intrude the answer; but when we find that at this dangerous point of the inquiry modern science is true to her first principles, and seeks to supply the missing evidence by processes that spring from the most exact of all the sciences—viz., mathematics—we feel that the half conclusions already arrived at may be at least so far trusted that we may indulge in the hope of at last finding a secure basis upon which to rear a true theory of nature. I here allude to the labours that have led some of our highest mathematicians and physicists to the conviction not only that atoms exist, but even to an approximative measurement of their size.

"The influence of physical investigations such as these upon our own special department of work—chemistry—has been indeed great, involving many changes of doctrine amongst its professors, and most bewildering modifications of language and even of character. In opposition to this march of modernism a voice has sometimes been heard protesting that the experimental work of the laboratory should be kept distinct from all hypotheses and systems; but though the warning may not have been without its value, nor altogether wrongly urged in some quarters, there can be little doubt that the alliance of the two streams of thought has served in a wonderful degree to strengthen the force of both, and to open and illumine many of the paths that led out into the unknown. Dalton's grand hypothesis subserves the great process of discovery with apparently more and more certainty, and has, since its enunciation, constituted the only practical starting point for all we possess entitled to be called a theory of chemistry. That great section of the subject, the chemistry of the Carbon compounds, which has developed so amazingly and so rapidly, could scarcely have passed beyond its first steps but for the suggestive aid afforded by the method of grouping hypothetical atoms; nor could such doctrines as those of "compound radicles," of "types," and of "substitution," which have assisted so largely in this wonderful progress, have been conceived but for the fundamental union of the physical and chemical ideas.

"As illustrating the tendency of modern chemical thought, I quote a sentence lately uttered by a master of the science.

"He says, 'Looking back, we see a logical sequence in the history of chemical speculation, and no doubt the next step will appear, after it has been taken, to follow as naturally from the present position. One thing we can distinctly see—we are struggling towards a theory of chemistry. Such a theory we do not possess. What we are sometimes pleased to dignify with that name is a collection of generalizations of various degrees of imperfection. We cannot attain to a real theory of chemistry until we are able to connect the science by some hypothesis with the general theory of dynamics. No attempt of this kind has hitherto been made, and it is difficult to see how any such attempt can be made until we know something in reference to the absolute size, mass, and shape of molecules and of atoms, the position of the atoms in the molecule, and the nature of the forces acting upon them. Whence can we look for such knowledge? The phenomena of gaseous diffusion, of gaseous friction, and of the propagation of heat through gases have already given us an approximation to the size and mass of the molecules of gases. It is not unreasonable to suppose that a comparative study of the specific heat of gases and vapours may lead to some approximate knowledge as to the shapes of their molecules, and a comparison of such approximate results with the chemical constitution of the substances may lead to a hypothesis which will lay the foundation of a real theory of chemistry. We do not know when the change will take place, or whether it will be gradual or sudden, but no one who believes in the progress of human knowledge, and in the consistency of nature, can doubt that ultimately the theory of chemistry, and of all other physical sciences, will be absorbed into the one theory of dynamics.'

"So speaks Professor Crum Brown.

"It must be admitted that these views may, in their turn, have to yield to others of broader significance and deeper grasp of truth, but, for the present, they contain that great element of comfort to which I have alluded, the prospect of a veritable theory of all the material sciences.

"Turning our glance to those sciences apparently more closely connected with the phenomena of life, I fear we have not yet reached quite so hopeful a period, the explanation of which, no doubt, lies in the vastly greater difficulties that attend the inquiry. Naturalists, histologists, functionists, therapeutists, biologists in every department of inquiry have examined, and questioned, and experimented with equal sagacity and enthusiasm; but a living organism is so unlike a test tube, the chance of conducting two experiments under identical circumstances is so remote, and the uncertainty of the answer to the question put in the experiment is so great, that a rapidity of progress in any way commensurate with that of the more tangible sciences is clearly impossible. There also exists another hindrance to the progress of biological knowledge, to which I must just make reference, the idea that the subject of life is sacred, and must not be touched by mortal. I would speak upon such a topic with all the reverence and humility that should accompany great ignorance, but I cannot at present see other than that the laws with which the Giver of Life has been pleased to surround that gift are as properly open to man's investigation as are those which surround His gift of light or heat; and I feel persuaded that until a much higher knowledge of these laws than we now possess is attained, it is hopeless to expect a rational and scientific application of those agents which we know will affect life. Whether life be a force *sui generis*, a controller of force, or some grand concurrence of force—whether the secret will for ever elude the grasp of man's search or whether some future biologist will be able to include *his* science also as a branch of dynamics, I, of course, cannot pretend to say; but I reverently claim it as a legitimate subject of scientific investigation, and one in which every practitioner in the art of medicine is profoundly interested. At present, however, I believe I may say we have no glimpse of a true theory of life at all parallel to that given us of the other forces of nature by Professor Crum Brown.

"Nevertheless, pray believe that biological science advances, and in none of its branches appears to lack earnest and enthusiastic workers.

"Now, I have spoken of an art as the practical application of scientific principles to some useful purposes. As an illustration let me adduce the art of telegraphy, which was commenced with a fair knowledge of the principles involved, and matured by rational processes into one of the wonders of the age. But I am aware that many an art has been discovered and practised long before the principles upon which it depended were ever perceived. Shall I mention the smelting of iron and the manufacture of glass, as ready illustrations of this fact? But all such practices bear the relation to general knowledge that isolated experiment bears to science; they are not rational but empirical, and progress in such arts is laboured and slow, and is attended with many mistakes and much disappointment.

"If in these few considerations I have been so fortunate as to enlist your acquiescence, we shall probably be of one mind in our general estimate of the art of medicine, of which we have said that our own occupation, pharmacy, is a branch.

"The blessed instinct to attempt the alleviation of pain and sickness appears to have impelled mankind very early in his social history into something of a practice of medicine. It would be foreign to our purpose now to trace the story of the development of that practice into an art, but I wish to point out that, as science and the scientific method itself are but the things of the last few centuries, medicine must have been, in past times at any rate, pure empiricism.

"One feels no pain in making this statement—it needs but a very slight effort of virtue to pity one's ancestors; but if we have to say that for the most part empiricism still rules in the practice of medicine, some of us may feel a little shock.

"The assertion, however, should be interpreted as disparaging to neither physician nor pharmacist. It is the duty of each to do the best he can under the circumstances that surround him. If it be the general expereince, gathered goodness knows how, that bark cures ague, the physician will wisely continue to administer bark, even though he be unable to detect the process by which the remedy acts. If the combination of a certain base with one chemical produces an insoluble inert mass, and with another a soluble and active remedy, the pharmacist will most properly suggest the latter, even though unable to explain the cause of the difference. The sciences which should tell them of these mysteries have been to the present moment dumb, and until more light appears the practitioners must do their best with the glimmers of their respective experiences.

"Were they ever so anxious to escape the trammels of empiricism, and adopt the purely scientific method in their respective arts, would it be possible to do so? What is an intermittent? What is solubility? Can science answer these first questions? Possibly she may some day, but most certainly she cannot now.

"I do not mean to assert that the scientific method finds no place in the practice of modern medicine. It could not, for instance, be affirmed that the introduction of such remedies as chloroform and chloral hydrate was entirely empirical, or that the attempt to substitute the alkaloids for the crude drugs yielding them was other than a step towards rational therapeutics; but, all credit being frankly given for these and many other most worthy efforts to apply our fragments of knowledge to the art of medicine, the bulk of its practice rests upon sheer experience. Hence those curious compound formulæ that figure in our pharmacopœias, and the still more curious prescriptions we sometimes see in which these *compounds* are again directed to be mingled with two or three other *compounds*, until the complexity of the remedy is such as to appear calculated to puzzle not only the disorder but even Nature herself. Still these Mithridatic remedies have been found to 'do good,' and the issues (in all opportunities for experiment) are so important that one cannot wonder conservatism rules, and that these fine old formulæ survive the many perils of many editions.

"In the meantime, notwithstanding the great advance science has made all round the subject of medicine, it is still powerless to raise it out of its empiricism; and of our own art, pharmacy, I am compelled to say that its practice at the present moment is singularly like what it was in the days of my pupilage. A few new remedies, a few improved processes, and all is told; and for this the pharmacist is sometimes taunted and his art contemned. But could it possibly have been otherwise? The part is not greater than the whole; and until the great art of medicine has entered upon some new and higher development, the branch, pharmacy, must attend her in her more lowly course.

"It may appear but a poor conclusion this—to contend in the first place that an art rests upon certain sciences; to go on to show how wonderfully those sciences have developed; and, finally, to be driven to admit that the art has nevertheless remained stationary. But after all here is no real contradiction. Those discoveries which are to bridge over the space between the vital and the physical forces have yet to be made; and hence the application of physical knowledge, how great soever it may be, to the influencing of vital phenomena is in great part delayed.

"But this is only delay, and need not diminish our faith, that one day the physician may practise his art, by the light of pure science, with a confidence and certainty in no degree less than that of the physicist. On the contrary, the wonderful progress in material science that I have just dimly sketched is our justification for the hope that such will be the issue.

"And the process? Well, the process must be the same as that which to the present time has been attended with such rich reward—work, laborious and patient work, in which we pharmacists must take our share, for we, as well as practitioners in medicine, are daily groping amidst the hidden things of truth, and each one must struggle to bring something to the light.

"At this point let me hazard one reflection:

"Those that work side by side might surely, with some advantage to the result, work hand in hand; and when whole realms of work appear to be destined for the *joint* labour of the physician and the pharmacist, may it not be hoped that they will one day occupy them with a fellowship a little more cordial than, let me admit, is quite possible at the present moment.

"In therapeutical chemistry alone is scope for such united work as might help in a wonderful degree to the attainment of the hoped-for light, and in no direction amidst the many that must still be explored would it seem that physician and pharmacist might more usefully work—the one to the help of the other—than this, *provided each brought to the task the requisite qualifications.*

"At the outset of my observations I declared my intention not to direct them especially to our students; and yet what I happen to have said should appeal more to the young amongst us than to the mature. The training and the knowledge that were spoken of as necessary for the proper fulfilment of our high duties can only be acquired in youth, and hence in this, as in all discourses that involve an aspiration for progress, the speaker is compelled to appeal to the younger portion of his audience. I do so now most earnestly, and beg you, young gentlemen, for the honour of our calling, to use your present opportunities well. You have adopted a definite line of life; some of its duties are mechanical, some, as we have seen, are intellectual; equip yourselves thoroughly for both; glory in doing your trade honestly and well, glory in doing your best to advance knowledge.

"In the actual practice of the healing art the pharmacist is content to regard his place as a humble one; but in the sphere of those labours that are slowly, perhaps, but surely forging out the principles upon which that art must ultimately rest, he may claim what place he chooses; and in this labour he will find himself the ally and comrade, not of this professional man nor of that, but of the whole glorious band of beings whose bright aim and purpose has ever been to fulfil their utmost duty and to leave mankind wiser and more noble than they found him."

Mr. Hills, who was received most cordially, said—

Ladies and Gentlemen,—I rise to express my great admiration of the address of the President of this Pharmaceutical Association, and to move a vote of thanks to him upon this occasion. I esteem it a great privilege to meet you here this evening. It is a pleasure which I have promised to myself to pay a visit to my friends in Bristol, and at the same time to see what they were doing. For I read the reports of the proceedings of all the local associations in the *Journal*, and I have read so much of your work in Bristol, and have observed that you were doing it so wonderfully well, that I became very curious to attend one of your meetings and to see for myself. I have long been wishing to do so, and at last I have succeeded, and I assure you that I am delighted to have been present this evening. Your President announced me as the President of the Pharmaceutical Society of Great Britain, and I have the honour to hold that position; but I am here now more in my private capacity, as representative of a house in London which held a high position long before my time, which position it has fallen to my duty to maintain; and upon this point I will say a few words for the encouragement of my young friends now present. I came to London years ago quite a stranger, not knowing anyone connected with pharmacy, and with no other friend than my own perseverance. I walked from street to street in search of a situation, and after some ten or twelve days I succeeded in getting one, and I have remained in it all my life. I was fortunate in falling among excellent friends—Jacob and Frederic Bell—names which I know you honour as those of men who have done all in their power (especially Jacob Bell) to uphold the dignity of pharmacy. I hope my experience will encourage you young men to rely upon your own efforts. Sometimes we hear young men say, "We cannot do this or that;" but you may do anything you like if only you make up your minds to succeed. It gives me great pleasure to see so many of you here to-night, and I wish to encourage the younger members to come to these evening meetings, for I know there is much to be learnt by attending them. We have had evening meetings in London for thirty-two or thirty-three years, and I do not think I have missed being present at more than four during that time. I used to say to myself, "There are eight meetings in the year, viz., the first Wednesdays of the appointed months; for all those evenings I am *engaged*, and nothing shall interfere with my going to the Society;" and I wish my young friends to think of this, and never to miss an opportunity of coming here, where they may obtain much scientific knowledge and valuable information. The object of these meetings is to receive and also to give information, and it is for that purpose that we come to them, both to give and take, and I would again urge my young friends to miss no occasion which tends to their elevation in pharmacy. The Pharmaceutical Society has done a great work for advancing pharmaceutical science and pharmaceutical education; it has pretty nearly accomplished all that it can do as a central organization, and now we look to you to carry out this work and to extend these influences in the provinces. We are looking to you, all England is looking, to see what the Bristol men are doing; we expect you to set an example to the provinces, for it is necessary that these local associations should be multiplied throughout the country in order to prepare young men to take advantage of the Pharmaceutical Society, and to extend its operations. And if you do not carry out what is expected from you—well, I really do not know what punishment is not in store for you. But I have no fear for you—I believe you to be good men and true, desirous of doing all in your power to elevate your calling, and to do your duty towards mankind, particularly when you are encouraged by the presence of so many charming ladies as I now see before me. It is more particularly the duty of the younger members to uphold the position which pharmacy has attained. Since my first coming on the boards many good men have passed away—my time is coming—and therefore we look to you. Consequently, let me implore you to think seriously; not only to think seriously, but to act resolutely, and to do all you possibly can for the elevation of your calling. It has been a great pleasure to me to listen to your President's address, as well as to meet in their own homes friends whom I have known for so many years, and with whom I have been for a long time associated in the Pharmaceutical Society. I have also to thank you for your kind reception of my name when it was announced to you early in the evening. Although President of the Society, I am really down here as a friend, to be amongst you socially, and, if I can, to be of some use in carrying on the good work which you have hitherto done so wonderfully well. In conclusion, I beg to move a cordial vote of thanks to the President of the Bristol Pharmaceutical Association for his most excellent and elaborate address this evening. (Prolonged applause.)

Mr. Schacht briefly acknowledged the compliment, and the proceedings terminated.

Parliamentary and Law Proceedings.

Conviction under the Pharmacy Act.

At the Woburn Petty Sessions, held on Friday, October 16, Richard Chapman was summoned, charged with "having sold poison—to wit, prussic acid—without affixing the name of the article and the name and address of the seller to it."

Mr. Flux, solicitor, attended on behalf of the Pharmaceutical Society, and conducted the prosecution.

Mr. Ward, clerk to Messrs. Flux and Co., proved having, on the 12th of October, applied at the shop of the accused to have a prescription compounded; that he saw the accused, who undertook to prepare the medicine in accordance with the prescription, and he afterwards called and received back the prescription, together with a compound in a bottle which the witnessed produced; that he paid the accused one shilling as the price of the article, and was informed by him that the shop was his own; that witness afterwards removed the outer wrapper, and finding that the bottle was not labelled with the name and address of the seller, applied for a summons, and caused it to be served; that he afterwards returned to London, and handed the bottle to Dr. Redwood in the condition in which it had been received.

Dr. Redwood proved having analysed the contents of the bottle, and ascertained that it contained prussic acid. He produced the bottle, which was labelled only with the words, "the mixture as prescribed."

The accused called as his witness Mr. Vesey, of Woburn, surgeon, who proved that for thirty years the accused had been dispenser in his surgery, and deposed to his competency to compound medicines; that he had been examined at Apothecaries Hall, and obtained a certificate, which the witness produced. He had always borne an excellent character. That accused did not hold himself out as a chemist and druggist, but only as a dispenser of medicines.

Cross-examined by Mr. Flux, the witness would not pledge his oath that the accused did not display in his window a sign bearing the words "Dispensing Chemist." The accused had no certificate other than the one produced, which was to the purport that he was competent to act as assistant to an apothecary. That the accused was not a duly qualified medical practitioner nor a registered chemist and druggist. He believed the accused to be competent to act as a surgeon or apothecary, or to be admitted to the register if he chose to submit to the examination.

Mr. Flux submitted that a case was established for a conviction, and that it had not been met by the defence. He was not instructed to press hard upon the accused, but he did press for a conviction, which should operate as a warning to the accused and others, and vindicate the law.

After consultation the Bench decided that the accused must be convicted, and accordingly fined him five shillings, and ordered him to pay the costs.

Apollinaris Water.—Important Case under the Trade Marks Act.

Eugene Fisher, mineral water manufacturer, of Park Road, Camberwell, appeared at the Lambeth Police Court, on Saturday, the 17th inst., in answer to a summons taken out against him by Mr. Stavely Power Wilkinson, secretary of the Apollinaris Company (Limited), for having, on the 8th day of September, with intend to defraud, unlawfully enclosed a certain article—to wit, mineral water—in certain bottles having thereon the trade mark of the Apollinaris Company. Mr. George Lewis appeared for the complainants, and Mr. Fullagar defended.

Mr. Lewis opened the case at some length, and observed that it was one of great importance, particularly to the public. The company had obtained a concession, at great expense, to import a water from Prussia, which was largely drunk, and strongly recommended by medical men. The defendant was now charged with enclosing a water he himself had manufactured, in bottles bearing the label and trade mark of the company. It was therefore highly necessary for proceedings to be taken, in order to protect the public and warn them against imposition. He should ask at the close of the evidence that the defendant should be sent for trial.

Henry Dorresugh said he was in the employ of defendant, up to a few weeks back, in washing bottles bearing the labels of the Apollinaris Company. When cleaned the bottles were filled from a tap of a machine on the premises, corked up, and wired. When the labels came off in the washing they were dried, but he did not know what was done with them. He had washed two or three hampers of such bottles.

Mr. James Alfred Wanklyn, analytical chemist, of Fitzroy Square, said he had examined six bottles labelled "Apollinaris Water" brought to him. The water was found to contain the rate of 84 grains of chloride of sodium in one gallon, 6 grains of sulphate of lime, 12 grains of carbonate of lime, and 12 grains of sulphate of magnesia. There was a perceptible quantity of lead. The water was not clean, and there was a perceptible quantity of organic matter. He had also analysed a bottle of water from the springs as supplied by the company. It was devoid of lead, and contained hardly a trace of organic matter. It contained a quantity of phosphates. The real water contained about 270 grains of solids per gallon, and the spurious water 114 grains. They were utterly distinct, and no chemist could mistake them. The spurious water, habitually drunk, would be injurious to health, but otherwise not.

After some further evidence Mr. Lewis asked for a remand, in order to enable him to complete the case.—Mr. Fullager said he had several witnesses to call.—Mr. Lushington directed a remand, and agreed to accept the defendant's own bail to appear on the next occasion.—*Standard.*

Review.

An Introduction to Pharmaceutical and Medical Chemistry (Theoretical and Practical). Arranged on the Principle of the Course of Lectures on Chemistry as delivered at the South London School of Pharmacy. By Dr. John Muter, M.A., F.C.S. London: William Baxter, South London School of Pharmacy.

We are glad to welcome an addition to existing means for enabling the student of pharmacy to make intelligent acquaintance with one of his most important subjects. After a careful examination of Dr. Muter's manual, we have little doubt that it will be found useful, not to the student merely, but to the practising pharmacist, and it is probable that the latter will be better able to appreciate its contents than the former; for though, as a rule, the style is clear and terse, certain parts of the volume, more especially those which are devoted to what is fundamental in chemical science, are written with a condensation so condensed that we fear the student's inability to see the fulness of meaning which lies behind. From the moment the author commences to treat of the physical and chemical characters of the elements and their compounds, he proceeds with a diction which is gratefully free from encumbrance, and glides along with a smoothness which begets confidence. In this part of his subject the author is evidently at home. Would we could say as much for Chapter I., in which the modern theories of chemistry are discussed! We hope, for the sake of the embryo pharmacist, that he will not depend on any one book for an explanation of chemical theories, but least of all on this. Here, where liberal filling up would meet with ample and immediate results of most profitable kind, there is little besides the dry bones of theory. Some of the most important physical relations of atoms are dismissed with not much more than a good dictionary definition of the terms with which these relations are identified. The section on "salts and their mode of formulation, as based on a knowledge of atomicity," must be excepted from this general condemnation. Yet even here, where there is most to praise, we find much to blame. It is stated, for example, that "hydrochloric acid (HCl) is proved to be an acid because, by presenting a metal to it we can displace the H, and form a metallic chloride, such as potassium chloride (KCl)." Would the author have his student reader to conclude that water (H_2O) is proved to be an acid, because by presenting a metal to it, we can displace H, and form a metallic hydrate, such as potassium hydrate (KHO)? There is nothing here contrary to such a conclusion. In the same section we read:—"The radical SO_4 being a dyad, the formulæ of its compounds, first with a monad radical, such as potassium, secondly with a dyad radical like calcium, and thirdly with a hexad, say ferric iron, will be as follows:—

Potassium sulphate . . .	$K'_2 SO''_4$.
Calcium sulphate	$Ca'' SO''_4$.
Ferric sulphate	$Fe^{vi}_2 3SO''_4$."

In the ferric sulphate we have a balance of value similar to that produced by two threepenny pieces on the one hand, and six pennies on the other. One more example will suffice. The radical of phosphates is PO'''_4. Phosphoric acid (the radical combined with hydrogen) will therefore be $H'_3 PO'''_4$. Just as three pennies are equal in value to one threepenny piece." No exception can be taken to the admirable illustration which concludes this extract, but we do object to the statement that the formula for ferric sulphate shows a balance of value similar to that of two threepenny pieces on the one hand, and six pennies on the other; we should rather say, as a matter of fact, the balance is similar to that of two threepenny pieces with three sets of twopence, a simile subsequently employed in considering the formula of calcium phosphate, $Ca''_3 2PO'''_4$. The formula given for ferric sulphate, however, does not agree with either of these statements. It more readily suggests the unequal comparison of two sixpences with three twopences. Dr. Muter would seem to have been led into error in this instance, by a desire to reconcile the statement (repeated at p. 111) that iron in the ferric condition is hexad, with the formula of ferric sulphate. The fact is, iron is hexad in the ferrates, *e.g.*, $H_2 Fe O_4$, or not at all. Atomicity is a property of the atom, or we do not understand the meaning of the word. But Dr. Muter, finding that the two atoms of Fe in a molecule of ferric sulphate have an aggregate atom-fixing power of six, speaks of them together, and calls the double atom *hexad.* Why not say that carbon, which is tetrad in methyl hydride CH_4, is hexad in ethyl hydride C_2H_6, and octad in propyl hydride C_3H_8? The same reasoning would make carbon hexad again in benzol C_6H_6. Even if it be allowed that the above is a proper treatment of the iron atoms, the formula is not correctly written. It should be $(Fe_2)^{vi} 3 (SO_4)''$. What must be the mental obfuscation of the student, who, after being told that oxygen is a dyad, finds it occasionally represented as a triad? It is undoubtedly so represented in the formula for calcium phosphate $Ca''_3 2 PO'''_4$, which, if numerals and dashes are to be used, should be $Ca''_3 2 (PO_4)'''$.

The second chapter is an excellent digest of the practical operations employed by the chemist, such as solution, precipitation, filtration, etc. Here also will be found directions for taking specific gravities, which we commend to the careful attention of the student, as well as short notices of qualitative, quantitative, and spectrum analysis. With regard to the section on Circular Polarization with which this chapter closes, we may say that Nicol's prism is formed of *one* crystal of calx spar divided in the plane which passes through the obtuse angles, and the halves united in the same position with Canada balsam; and that for the explanation of "right and left-handed" to be of any value, it requires to be supplemented by a statement of the order of the colours assumed by the transmitted ray, according as the prism is turned to the right or left. This order is from red to violet; and if, to produce it, the prism must be turned to the right, the body under examination possesses right-handed polarization; if to the left, left-handed.

The classification employed in treating of the elements and their compounds is somewhat unusual, and we are disposed to think may be found almost as useful as those more commonly met with, for enabling the student to grasp and retain the facts. There is no distinction between the so-called Organic and Inorganic Chemistries. The simple basylous radicals first receive attention in the order of their atomicity, hydrogen heading the list. A general description of the sources, isolation, and characters of each metallic radical is supplemented, except in the case of hydrogen (*hydrium*), by a tabular arrangement of the relative and distinctive reactions of its salts. The more common compound basylous radicals, methyl, ethyl, etc., are then introduced, to give way presently to the acidulous radicals and their compounds. Under chlorine will be found all compounds generally met with in pharmacy containing this element, viz: chlorides, hypochlorites, chlorates, chloroform, chloral, etc., with information on detection, separation, and estimation. Under oxygen we make acquaintance with oxides and hydrates, then with alcohols and their derivatives as being closely connected with oxygen. Sulphur, nitrogen, phosphorus, etc., receive similar treatment. The chapter on ammonia and its derivatives affords an opportunity for describing the alkaloids, while an appendix to carbon comprises the hydrocarbons, amylaceous and saccharine bodies, glucosides and aloins, albuminous, and lastly, pigmentary substances. This classification, though useful in the aspect suggested above, will not, we think, be found to adapt itself with facility to analytical methods.

We think it a pity that the British Pharmacopœia processes should have been copied to swell a book of sufficient bulk without them. If the steps of each process were explained there would be some excuse for it, but in that case one process might be chosen as typical of a class.

Under hydrogen it is stated that *nascent* (an adjective) is a point of time, in these words—"by the term *nascent* is meant the instant of its liberation." The statement that iodide of ammonium is not used in pharmacy (p. 217) is one which most readers will be able to correct for themselves. "The oxidation of an alcohol first results in the formation of a body called an *aldehyd*" (p. 300). This is not a general truth,—only primary alcohols yield aldehyds. Why should the acid sulphate of quinine be called quinine *hydrosulphate* (p. 596) rather than the neutral official salt? The term used to be employed to indicate a compound of a totally different acid radical, and being likely to cause confusion, should not, we think, be applied to either of these salts. The name *Asagræa officinalis* was given out of compliment to Dr. Asa Gray; to spell it thus—Assagræa (p. 622)—robs the term of its significance. On p. 635 it is stated that hypophosphites were originally introduced as constituents in *Parrish's Chemical Food*. We presume *Churchill's syrup of the hypophosphites* is here intended. On p. 606 it is stated "*Injectio morphiæ hypodermica*, B.P., is thus prepared":—the ingredients follow, but the *modus operandi* is not given. We have looked carefully, but in vain, for any mention of the metrical system. The above errors we have discovered in our very careful perusal of Dr. Muter's book, and we note them now with no other intention than that they may be corrected in a future edition. The book is capitally printed on toned paper, and different kinds of type are used in such a way that the eye is instantly arrested in its passage over the page by some word, in which the meaning of a sentence or paragraph is focussed as it were. That the author found himself unable to amplify the introductory chapter is cause for regret; in its present form it detracts from the general usefulness of the work.

BOOKS RECEIVED.

Pharmacographia.—A History of the Principal Drugs of Vegetable Origin met with in Great Britain and British India. By Friedrich A. Flückiger, Ph.D., etc., and Daniel Hanbury, F.R.S., etc. London: Macmillan and Co. 1874. From the Publisher.

Notes and Queries.

AMMONIATED TINCTURE OF QUININE.—A much more elegant preparation of quinine in combination with ammonia, can be prepared by dissolving freshly precipitated quina in aromatic spirits of ammonia, containing in one fluid drachm either 1 gr. or 2 gr. of quinine.—Curtis and Co.

COD LIVER OIL EMULSION AND PHOSPHORIC ACID.—The following formula for an emulsion of cod liver oil and phosphoric acid is said by the *Druggists' Circular* to be used by Dr. Andrews, of the Utica Insane Institution. It is stated that although the fishy odour is not entirely neutralized, neither the odour nor taste of the emulsion suggests the presence of the oil to persons not familiar with cod liver oil:—

Cod Liver Oil	4 ounces.
Glyconin (see below)	9 drachms.
Aromatic Spirits of Ammonia . .	1 ,,
Sherry Wine	16 ,,
Diluted Phosphoric Acid	4 ,,
Essence of Bitter Almonds . . .	2 ,,

Add the oil to the glyconin *very slowly*, stirring briskly all the while, and then the other ingredients in the same order as they are written. The essence of bitter almonds mentioned is made by dissolving one drachm of the essential oil in eight ounces of alcohol. The *pyrophosphate of iron cannot* be used in the mixture, on account of the free phosphoric acid, which causes its immediate gelatinization. The same decomposition has been remarked in other similar instances. The ammonia-citrate of iron, which is used sometimes, has not the same disadvantage, but offers another, that of turning the mixture unpleasantly dark unless the sherry wine be replaced by Jamaica rum, or some distilled liquor free from tannin.

GLYCONIN.—Glyconin, the preparation quoted in the above formula, is made by mixing five parts of concentrated glycerine with four parts of yolks of eggs, previously well beaten. It is said to keep almost indefinitely.

LEAD IN CITRIC ACID.—Mr. Reichardt, of New York, states that having met with a residue of 14 grains of lead from two pounds of citric acid dissolved in water, he was induced to obtain five specimens of acid from various sources, and found them all contaminated with the metal in similar proportions. The same impurity was found to exist in specimens of citrate of magnesia. It probably would have its origin in the leaden vessels used in the preparation of citric acid.

MERCURIAL OINTMENT PREPARED WITH GLYCERINE.—M. Melsens states (*Répertoire de Pharmacie*, ii. 483), that the addition of a small quantity of glycerine to the ingredient used in the preparation of mercurial ointment causes the more rapid extinction of the mercury. He uses 125 grams of mercury, 108 grams of lard, 12 grams of almond oil, and 5 grams of glycerine. The oil, glycerine, and mercury are first mixed together in a glass mortar. After triturating for ten minutes, the mercury becomes divided into small globules; the lard is then added a little at a time, and the ointment is finished.

MUCILAGE OF GUM ARABIC.—Messrs. Archer and Co., of Norfolk, Va., state (*Amer. Journ. Pharm.*, Oct., p. 468.) that the inconvenience arising from the instability of mucilage of gum arabic during the summer months may be overcome by substituting "tolu water" for water. The "tolu water" is prepared as follows:—

Tinct. Tolu (saturated)	f℥ij.
Carb. Magnes.	℥iv.
Water	Oij.

Rub the tincture first with the carbonate of magnesia, then with the water gradually added, and filter. The mucilage thus prepared has a faint odour and flavour of tolu, which has not been found objectionable. It is suggested that tolu prevents change in liquids in the same manner as benzoin obviates rancidity in unctuous substances, and that this property might be utilized in the preparation of many syrups and mixtures which are particularly unstable.

SULPHATE OF QUININE PILLS.—Mr. H. P. Reynolds has published the following formula for quinine pills (*Amer. Journ. Pharm.*, Sept., p. 404):—

Take of Sulphate of Quinia . . .	600 grs.
Tartaric Acid	100 grs.
Glycerin, pure	75 minims.

Rub the quinia and acid together in a mortar to a fine powder, till no appearance of crystals remains; add the glycerin—just 75 minims, no more nor less—and continue the trituration till the powder becomes adherent, when it should be beaten into proper form for handling and divided into the required number of pills. He states that the mass is firm, solid, rolls well, and does not set for some hours, and that the pills will be found small for their weight, very white if rolled in starch powder, and, however old or dry, perfectly and entirely soluble. He repeats the caution that the quantity of glycerin is just right, though it seems at first insufficient for such a bulk of quinia; in connection with the tartaric acid it does the work, though requiring patient trituration. Even a very few drops of glycerin more than the proportion given will render the mass inconveniently sticky.

Pharmaceutical Education.

Sir,—In the *Pharmaceutical Journal* of October 17, I read a letter from Mr. Siebold, beginning with a eulogy on the opening address delivered by Mr. Giles to the students in the Society's School of Pharmacy, and ending with a proposed plan for putting down the strongholds of cram.

I also read Mr. Giles's address with great interest and pleasure, and possibly I think as highly of it as Mr. Siebold can do. I most cordially agree with him in all that he has said on it.

No one more heartily hates the abominable system of cram than I do, which he (Mr. Siebold) rightly describes as an "unscrupulous attempt to defraud the examiners, the public, and, above all, themselves."

His plan, however, appears to me, if not altogether *impossible*, at least *impracticable*. Every chemist's assistant cannot go to London to undergo a "compulsory curriculum of education." And another and more powerful reason why his plan must fail is, that many a student finds it hard work indeed to find the requisite supply of the "needful" to pay his examination fees, and would consequently find it altogether impossible to provide a sum sufficient to enable him to go through a "ten months' course of training," however much he might wish to do so.

No one will deny that many students who never saw Bloomsbury Square have passed the Society's examinations as honourably and as creditably as any who went through a lengthened and expensive "curriculum of education" there.

Perhaps Mr. Siebold can show us an outlet from these difficulties. By so doing he will greatly oblige

A Country Student.

C. Roberts.—(1) Nitrate of bismuth is directed to be pressed with the hands, because that is the usual and most convenient way of applying such pressure as is required. (2) Oil is employed because it is found to be an ingredient which assists in producing the effects sought for by the use of the compound.

"*Lapis.*"—By Sal Sodæ is no doubt intended crystalline Carbonate of Sodium. In the 'Pharmacopœia Germanica,' Sal Sodæ Crudus is described as the rough Carbonate of Sodium (washing soda), and Sal Sodæ Depuratus as the purified Carbonate of Sodium used in medicine. As you live at Runcorn, surely you cannot require a description of this manufacture?

"*A Correspondent.*"—The foreign liquorice root may be distinguished by its taste, being not so purely sweet as that of the English root, but having a slightly bitter after-taste. A transverse section of the root shows the medullary rays wider apart and the cortical portion more distinct than in the English root. The underground stem is often mixed with the root, but may be recognized by its evident pith, and by the absence of the transverse striæ so conspicuous in the root. It is also less sweet.

"*Neston.*"—(1) The use of the title of "chemist and druggist" is limited by the Pharmacy Act, 1868, to persons on the Register of Chemists and Druggists. (2) Probably the decisions were based on the fact that the plaintiffs were not registered medical practitioners. (3) Yes.

W. R.—(1) We have been unable to find any authority for the statement in the dictionary mentioned. (2) Pereira states, that the term calomel (from Gr. *kalos*, 'good,' and *melas*, 'black,') was first used by Sir T. Mayenne (who died in 1655), in consequence, according to some, of his having had a favourite black servant who prepared it; according to others, because it was a *good* remedy for *black* bile. (3) In the 'Pharmacopœia Londoniensis,' 1721, under "Mercurius Dulcis Sublimatus," it is said, "quod si quater aut pluries sublimetur, Calomelas nominatur." In the 'Pharm. Lond.,' 1788, the subchloride of mercury is indexed as "Calomelas—*olim* Mercurius dulcis sublimatus." (4) Calomel acquires a yellowish tinge upon being triturated in a mortar.

W. Pitchford.—"Cinnabar of antimony" is a synonym for mercuric sulphide, or vermilion.

T. D. V.—The liquefaction is due to the physical properties of the two substances, but we have seen no satisfactory explanation of any other change which takes place.

R. H. Rowell.—The exemption appears to extend only to quinine wine prepared and sold as a preparation of the British Pharmacopœia.

Sligo.—As far as we know, there is nothing to prevent a licentiate apothecary using the title "Dr.," or practising as a doctor in England (subject to the question of the recovery of fees under the Medical Act, 1858).

Messrs. J. Lescher, Son, & Co.—We cannot insert your letter in its present form, but should be glad to receive a contribution relative to the subject, with any facts appended, showing that at the present time the article you manufacture is the only pure one in the English market.

Communications, Letters, etc., have been received from Mr. Upton, Mr. Balkwill, Mr. Brown, Mr. Rimmington, Mr. Hughes, Mr. J. Wyld, Mr. Priestley, Mr. Harper, "A Young Pharmacist," "Cram," "Extortion," W.W.

CROTON CHLORAL.*

BY DR. R. ENGEL.

Notwithstanding that since Dr. Liebreich first brought croton chloral under the notice of the medical profession it has been the subject of numerous physiological experiments, very little is generally known of it especially in a chemical point of view. The object of the author in this paper, therefore, has been to describe the preparation, and the chemical, physiological, and therapeutic properties of this substance, which is now prepared on a large scale in Berlin.

Constitution.—Ordinary chloral is an aldehyd; it is the hydride of trichloracetyl, $C_2Cl_3O.H$. Croton chloral is the hydride of trichlorocrotonyl, $C_4H_2C_3O.H$, or the aldehyd of crotonic acid, $C_4H_5O.OH$, in the radical of which three atoms of hydrogen have been replaced by three atoms of chlorine.

Preparation.—Krämer and Pinner † were the first to obtain croton chloral by passing a current of chlorine into aldehyd during twenty-four hours. The action is very energetic at the commencement of the operation, so that it is necessary to surround the vessel containing the aldehyd with a refrigerating mixture, and it is only towards the end that the temperature is raised to 100° C. During all the time of the action of the chlorine upon the aldehyd large quantities of hydrochloric acid are disengaged. The product obtained is submitted to fractitional distillation, and a liquid is thus isolated passing over between 163° C. and 165° C., which is croton chloral.

Wurtz had previously studied the action of chlorine upon aldehyd ‡, and had indicated among other products of the reaction, chloride of acetyl, and had shown that ordinary chloral is not produced; but the formation of croton chloral escaped him. The reason was that Wurtz caused chlorine in excess to act upon aldehyd, whilst Krämer and Pinner passed a current of chlorine into the aldehyd until it was no longer absorbed.

The production of croton chloral under these conditions is easily understood, since Kekulé has shown that acetic aldehyd, under the influence of various saline solutions, and more easily still under that of hydrochloric acid, is condensed, with the elimination of water, into croton aldehyd:—

$$2\,\underbrace{C_2H_3O.H}_{\text{Aldehyd.}} = \underbrace{C_4H_5O.H}_{\text{Croton aldehyd.}} + \underbrace{H_2O}_{\text{Water.}}$$

Further, aldehyd, under the combined action of heat and a little hydrochloric acid, may even be combined with other aldehydes, with the elimination of water, and new compounds be thus engendered, which are themselves aldehyds.

In the action of chlorine upon acetic aldehyd a substitution is commenced in the latter, which results in the formation of hydrochloric acid. This acid determines, as has just been seen, the formation of croton aldehyd; upon which the substitutive action of the chlorine then goes on. The formation of croton chloral is thus readily explained.

Physical and Chemical Properties.—Anhydrous croton chloral is a colourless oleaginous liquid, having a peculiar odour, recalling that of ordinary chloral. It is insoluble in water, but, like ordinary chloral, it combines with water to form a crystallized hydrate. The hydrate of croton-chloral crystallizes in white nacreous spangles. It is slightly soluble in cold water, more freely soluble in warm water, and extremely soluble in alcohol (Krämer and Pinner). It dissolves more readily in glycerine than in water (J. Worms).

It is known that ordinary chloral is decomposed under the influence of caustic potash into chloroform and formiate of potassium:—

$$\underbrace{C_2Cl_3O.H}_{\text{Chloral.}} + KOH = \underbrace{CHO.OK}_{\text{Formiate of Potassium.}} + \underbrace{CHCl_2.Cl}_{\text{Chloroform.}}$$

Under the same influence croton chloral breaks up into allyl-chloroform and formiate of potassium:—

$$\underbrace{C_4H_2Cl_3O.H}_{\text{Croton chloral.}} + KOH = \underbrace{CHO.OK}_{\text{Formiate of potassium.}} + \underbrace{C_3H_3Cl_2.Cl}_{\text{Allyl-chloroform.}}$$

But allyl-chloroform is excessively unstable, and decomposes rapidly into hydrochloric acid and bichlorallylene:—

$$\underbrace{C_3H_3Cl_2.Cl}_{\text{Allyl chloroform.}} = HCl + \underbrace{C_3H_2Cl_2}_{\text{Bichlorallylene.}}$$

Physiological and Therapeutic Properties.—According to Liebreich,* croton chloral, administered internally, rapidly produces slumber similarly to ordinary chloral, but without its use being followed, as in the case of the latter, by lowering of the pulse and respiration. Even after the administration of very high doses of croton chloral the pulse is not reduced.

The author thinks that it is not to the first product of decomposition (allyl-chloroform) that hypnotism is due. Allyl chloroform, being very unstable, breaks up immediately, and he thinks therefore the action of croton chloral should be attributed to bichlorallylene. Moreover, Liebreich has found that bichlorallylene, when administered to animals, does not reduce the circulation or respiration. Comparing the effects of chloroform and chloral on the one hand, and bichloride of ethylene and bichlorallylene on the other, he considers himself justified in asserting that whilst the trichlorinated substances act upon the brain, spinal cord, and heart, the bichlorinated substances act only upon the brain and spinal cord. In none of his experiments has Liebreich recognized any hurtful effects on the stomach or any other organs; and he reports that he has employed it very successfully in cases of facial neuralgia, the pain ceasing frequently before sleep is produced. Jules Worms, however, asserts that croton chloral is not so generally tolerated as chloral, and Georges Gay says that its narcotic action is more uncertain.

Croton chloral is hypnotic in doses of from half to one gram. It may be administered in solution in water, or in glycerine. The following is the formula employed by Jules Worms:—

Croton Chloral	1 gram.
Glycerine	60 grams.
Water	60 „
Oil of Peppermint	3 drops.
Simple Syrup	25 grams.

In a paper contributed to the *American Practitioner* by Mr. Louis Diehl, of Louisville, he remarks that croton chloral hydrate differs from the ordinary

chloral hydrate by its sparing solubility in cold water, and in the exceedingly irritant character of its vapour. Chloral hydrate, on the contrary, is freely soluble in water, and its odour when pure is not irritating. Nevertheless, nearly all commercial chloral hydrate has a more or less irritating odour, and it is inferred by Mr. Diehl that this is owing to the presence of croton chloral, formed either from aldehyd, contained as impurity in the alcohol, or from aldehyd generated by the action of chlorine. No experiments have, however, been made by him to prove the correctness of the inference.

Reporting upon a sample of croton chloral hydrate purchased in New York, the original source of which was unknown, he says, "It is a white, powdery substance, of a pearly lustre, apparently crystalline, and when triturated in a mortar has the appearance and feels to the touch like pulverized valerianate of zinc. Its odour reminds of ordinary chloral hydrate and iodoform; does not seem to be more pungent than that of ordinary commercial chloral hydrate, and not as much so as that of some samples I have noticed. Its taste is bitter and aromatic, recalling the odour of iodoform. It is more soluble in cold water than I should have expected from the characteristic, sparingly soluble, given it by its discoverers. Thirty minims of distilled water dissolve one grain readily. If another grain be added to this solution heat is required to dissolve it, and upon cooling and standing a short time a copious crop of well-defined crystals is obtained. Subsequent experiments proved it to be soluble in between twenty-two and a half and twenty-five parts of water, at a temperature of 60° F. In alcohol it was found to be freely soluble."

From these experiments it follows that croton chloral hydrate (commercial) may be dispensed in aqueous solution of a strength corresponding to two grains in the fl. drachm, and Mr. Diehl gives the following formula:—

℞.	Croton-chloral Hydrate	g. viij.
	Warm Water	fl. ℥ i.
	Simple Elixir	fl. ℥ vij.
Ft. solut.		

Owing to the alcohol contained in the simple elixir,* a larger quantity than two grains to the fl. drachm could, if desirable, be incorporated and held in solution by the above mixture.

CHEMICAL STUDIES OF THE PEPPERS OF COMMERCE.†

BY A. WYNTER BLYTH, M.R.C.S., L.S.A., A.K.C.,

Analyst to the County of Devon.

It will be indispensable for some time to come to accumulate facts on the properties of articles of food in the *pure* state. The exact amount of ash, the solubility of substances in different liquids, the specific gravity of the aqueous infusion, etc., many of them, when applied to foods, wholly uninteresting to the ordinary chemist, become of great value in the technical examination of articles suspected of adulteration. However unimportant some slight variation in solubility, for example, may be in a purely chemical sense, yet if that variation be, within certain limits, constant, it is of the greatest utility to the public analyst.

The peppers I have examined were obtained from the importers in the berry, and ground by myself; they are, I believe, specimens of pure pepper. The following are the methods adopted in the examination:—

The ash was burnt at a very low temperature in a platinum dish, supporting a chimney to increase the draught; the soluble ash was obtained by boiling the ash with water, filtering, evaporating the soluble ash down in a platinum dish, heating to dull redness, and weighing; the aqueous extract by putting 4 grammes of pepper in a large flask with 500 c.c. of water, distilling over 200 c.c., returning these into the flask, when cool, filtering, weighing and evaporating $\frac{1}{10}$th; the ammonia, by taking 5 c.c. of the last liquid and distilling it with 50 c.c. of alkaline permanganate by Wanklyn's method; and the alcoholic extract, by treating about 1 grm. of the dry pepper with repeated quantities of alcohol, and boiling for some time in a flask connected with a reversed Liebig's condenser. I have not yet estimated the piperine in the peppers; indeed, although it can be extracted with comparative ease, the crystallization of the alkaloid and the separation of the resin takes up so much time that the process, however satisfactory, cannot be very attractive to analysts, who have to examine a great number of samples in a short time.

Ash.

	Soluble Ash.	Total Ash.	
		Pepper in the Dry State.	Pepper in its Ordinary Condition.
	Per cent.	Per cent.	Per cent.
Penang	2·2120	4·189	3·8480
Tellicherry . . .	3·3800	5·770	5·3460
Sumatra	2·6260	4·316	3·3340
Malabar	3·4530	5·195	4·6740
Trang	2·5380	4·775	4·2110
A white pepper, ground by myself, bought at a retail shop	0·5584	1·120	0·7889
Long pepper . . .	4·4720	8·308	7·1543

The first five peppers give, as the mean of the soluble ash, 2·84 per cent. of the dried substance, the two extremes being respectively 3·453 and 2·212. The mean of the total ash of the five peppers is 4·845 per cent., the two extremes being 4·189 and 5·770.

Hygroscopic Moisture.

	Per cent.
Penang	9·531
Tellicherry	12·908
Sumatra	10·103
Malabar	10·548
Trang	11·664
Long pepper	10·778

It is worthy of note that, as the peppers were finely powdered and kept on the water-bath for many hours, besides water, the volatile oil would to a considerable degree be dissipated.

The total loss of weight may be stated generally at 11 per cent.

Alcoholic Extract.

	Grms. per cent. of Dry Pepper.
Penang	7·650
Tellicherry	7·836
Sumatra	6·450
Malabar	6·375
Trang.	6·300
The white pepper before mentioned.	7·650
Long pepper	2·600

The extract was thoroughly dried before weighing; it may be said to be never less than 6 per cent. in black and white peppers. The small extract yielded by long pepper is noteworthy.

† From the *Chemical News*, October 9, 1874.

Aqueous Extract.

	The Dry Substance yields to Water. Per cent.
Penang	18·335
Tellicherry	16·500
Sumatra	17·500
Malabar	20·375
Trang	18·175
Long pepper	16·825

The total ammonia yielded in the manner before mentioned, expressed in percentage:—

100 grms. of—

			NH_3.		Nitrogen.
Penang pepper	yield	to water	0·450	=	0·370
Tellicherry	"	"	0·450	=	0·370
Sumatra	"	"	0·375	=	0·310
Malabar	"	"	0·295	=	0·243
Trang	"	"	0·325	=	0·300
Long	"	"	0·175	=	0·144

As 100 parts of piperine contain 4·9 of nitrogen, if the nitrogen be considered as dissolved piperine, the mean of the piperine boiling-water takes up, and when cold retains, of the first five peppers = 0·017. The small yield from long pepper is a great distinguishing mark.

Barnstaple, September 23, 1874.

THE MANUFACTURE OF BORACIC ACID IN TUSCANY.*

BY P. LE NEVE FOSTER, JUN., C.E.

The production of boracic acid in Tuscany from the hot boiling springs and jets of vapour called *soffioni* is certainly one of the most important branches of chemical industry in Italy. The curious phenomenon of jets of vapour issuing naturally from the ground is met with over an area of comparatively limited extent, situated between Massa Marittima and Volterra. The hill-sides in many of the valleys of the tributaries of the River Cecina are studded with such *soffioni*, and numerous *lagoni*, or ponds of muddy blue water boiling vehemently, have been formed by the natural springs, acted on by these vents of vapour.

Towards the close of the last century (between 1770 and 1780) boracic acid was discovered in the springs of Monte Rotondo and Castelnuovo, by Hœffer, the chemist to the Grand Duke of Tuscany, and by Professor Mascagin, but no steps of any importance for utilising these springs for making boracic acid appear to have been taken until 1818, when Mr. François Lardarel, a Frenchman, established works on a small scale for the collection and extraction of this substance from the waters of the *lagoni* in the neighbourhood of Castelnuovo. At first his efforts were unattended with success, and, in a commercial point of view, may be said to have proved a failure, owing to the great expense of obtaining fuel for evaporating the water. At length the brilliant idea struck M. Lardarel of employing the heat of the natural steam jets to evaporate the weak solution from the *lagoni*, and this was the turning point in his fortunes. This method, which was first applied in 1827, had the effect of converting an unprofitable branch of industry into one of the most successful in Italy. At the present time there are no less than seven separate establishments belonging to Count Lardarel, all situated within a few miles of the little town of Castelnuovo, which may be said to be the centre of the boracic acid industry in Italy. These establishments are as follows:—

1. Lardarello, or Lagoni, of Monte Cerboli.
2. Castelnuovo, Val di Cecina.
3. Serrazeano, or the "Lagoni Solforei."
4. Lustignano, or the "Lagoni Rossi."
5. Sasso, or the "Lagoni di Acquavita."
6. Monte Rotondo, or the "Lagoni della Pianacce."
7. "Il Lago," where the works of San Federigo, San Eduardo, and La Collacchia are situated.

The works at Lardarello are the most important of all, and it is there that all the products of the other establishments are sent. The processes by which the acid is extracted being precisely the same at each, it will only be necessary to describe in detail those carried out at Lardarello. This little colony, which was founded by the late Count, is situated at a short distance from the village of Monte Cerboli, on the torrent Possera, and shows what might be done in other parts of Italy for improving the social condition of the working classes. There is a neat square, "La Piazza dell' Industria," surrounded by blocks of buildings, which on one side include the offices, church, museum of mineralogy, and schools, and on the other, the model lodging-houses for the workmen, stores, workshops for various tradesmen, such as tailors, shoemakers, etc., and a weaving establishment for giving employment to the wives and daughters of the workmen.

The *lagoni* are situated to the south of this little village, and consist of artificial basins constructed of coarse masonry, large enough to contain several *soffioni*. At the present time most of these *soffioni* are obtained artificially by boring, and are lined with sheet iron tubes from 25 to 30 centimetres (10 to 12 inches) in diameter. These borings are found more manageable, besides giving out more vapour than those formed naturally. The basins, or *lagoni*, are situated at different levels on the hill-side, and the uppermost is supplied with water conducted by a canal from near the Bagno del Norbo. After remaining in this basin for twenty-four hours, during which time it has been kept in constant agitation by the subterranean vapours, and has become of a slate blue colour, the water passes into a canal, and is conducted to another basin at a lower level, where it remains another twenty-four hours, and in consequence takes up an additional quantity of boracic acid.

The water, after passing through a chain of *lagoni*, where it is brought up to a strength of about 0·50 per cent. of boracic acid, is then conducted to a large tank, about 20 metres (66 feet) square and ½ a metre (1 foot 6 inches) deep, covered by a tiled roof supported on brick columns. Here it is allowed to settle, the impurities held in suspension are precipitated to the bottom, and the water leaves the tank in a perfectly clean state.

The next operation is to concentrate this weak solution of acid. This is effected by evaporating it in long lead pans, ingeniously heated with steam from the dry *soffioni*. These pans are about 60 metres (200 feet) in length by 2·50 to 3 metres (8 feet 4 inches to 10 feet) in breadth, arranged usually in three parallel lines under one roof, supported on columns, the sides being open so as not to impede the evaporation. The pans are supported on beams over low steam passages, into which the vapour is conducted by pipes from the *soffioni*. Formerly a masonry arch was built over one of the natural springs, and the steam collected in this manner; but these buildings were liable to be undermined, and attacked by the corroding influence of the vapours, and it is now found far more convenient to connect the pipes to the tube of an artificial boring, to say nothing of making a neater job and the arrangement being more under control. The pans have a number of divisions placed transversely across them, usually from 80 cent. to 1 metre (2 feet 7 inches to 3 feet 4 inches) apart. These divisions are 0·05 metres (2 inches) in height, and the pans are arranged so as to have a slight inclination from the end where the water is admitted towards the other, where there is a large and deep reservoir. The water is allowed to enter in a regulated quantity from the precipitating tank, and following from one division to another, it gradually evaporates, and after having passed over 50 to 60 divisions, it assumes a bright yellow hue, increasing in intensity as it approaches the end, where it runs into the tank or boiler. Every 24 hours this boiler is emptied, and its contents pumped up to

* From the *Journal of the Society of Arts*, October 9, 1874.

the crystallizing house, in which a series of vats about a metre (3 feet 4 inches) in diameter are placed. These vats being filled, the liquor is allowed to remain four days, during which time the boracic acid is deposited in crystals at the bottom and sides to a depth of a few inches, and the liquid that then remains is drawn off by removing a plug at the bottom, and conducted away by a drain to the evaporating house. Fresh liquid is then introduced into the water, and the same process is repeated until they are completely filled with crystals of boracic acid. As these crystals retain a large amount of water, they are, when removed from the vats, placed in large wicker baskets to drain, and are afterwards taken to the drying-house, where the contents are spread in thin layers on the floor, and stirred constantly with a wooden rake. It is then packed in barrels containing about 600 kilos. each (12 cwt.), and sent to Leghorn, where it is shipped chiefly for England.

The boracic acid manufactured in this manner contains about 13 per cent. of impurities, chiefly sulphate of lime, ammonia, alumina, and magnesia.

At the Lardarello Works there are 12 evaporating sheds, containing 35 evaporators. The average daily production is about 3,000 kilos. (3 tons), though some days as much as 4,200 kilos. (4 tons) have been made. The Castelnuovo establishment averages 26,700 kilos. (27 tons) per month, and the production of the other works is still less. The total annual production of the whole of the establishments belonging to Count Lardarel is estimated at 3,000 tons.

Notwithstanding the extreme simplicity of the whole process, it is a matter of surprise to many who have visited these works, and it is much to be regretted in the interests of science, that Count Lardarel (whose motto is evidently "rest and be thankful," instead of "progress") has not thought fit to employ a chemist at his establishment, and up to the present no progress has been made in this manufacture since the first application of steam by the late Count in 1827, although it is highly probable that, under the management of a scientific man, considerable improvements might be introduced.

M. Durval has an establishment for the manufacture of boracic acid at the Lake of Monte Rotondo, called also "Il Lago Solforei di Vecchiena," which has an area of about 18 acres. The water contains about 0·002 of acid. The produce of these works is sent chiefly to France.

At Travale, an Italian company, called the Società Anomonia Borica Travalese, have an establishment for extracting the boracic acid which is found there, though in a far more diluted state than at the *lagoni* of Count Lardarel, and although the process by which it is extracted does not differ in principle from that previously described, certain very important modifications and improvements have been introduced. These springs, which are called "I Lagoni delle Galleraje," are situated at a short distance from the village of Travale, in the valley of the Sajo, a little stream flowing into the Feccia and Merse tributaries of the Ombrone. Here the boracic acid is associated with sulphate of ammonia, which is extracted from the waters of a series of *lagoni* by evaporating apparatus, heated by the natural vapours of the *soffioni*, but as the sulphate of ammonia is worth only 35 francs per quintal, whilst the boracic acid is worth 50 francs, and the cost of production is almost equal, there is very little profit attendant upon its manufacture. The water of these *lagoni* contain about 500 milligrammes (about 7 grains) per litre (1¾ pint) of sulphate of ammonia. All the *soffioni* at this place have been obtained by boring, and this company are possessed of excellent tools for this purpose, by means of which they are enabled to bore to a diameter of 40 centimetres (16 inches). These borings usually meet water at a depth of from 15 to 20 metres (50 to 70 feet), though in one place a depth of 168 metres (560 feet) was reached before tapping these subterraneous sources of heat, viz: in a boring called "Il foro Pietro."

Another boring ("Il foro Carlo"), 73 metres (240 feet) deep, furnishes a supply of water holding boracic acid in solution, which rises to the level of the ground, as in an artesian well, its supply being equal to 600,000 litres (132,144 gallons) per 24 hours, of which only one-sixth part is at present utilized. This solution contains only 260 milligrammes (about four grains) per litre (1¾ pint) of boracic acid, which is given off at a temperature of 96° Cent. (205° Fah.). Here there is no basin, as at Lardarello, the water being led away direct by cast-iron pipes from the bore-hole to the precipitating tank, which is 18·50 metres (60 feet) in length, by 13·50 metres (45 feet in width), and 0·50 metre (1 foot 8 inches) in depth. The improvement that has been introduced here consists in heating the water in this tank by pipes, through which the vapour from a dry *soffioni* ("Il foro Filippo") passes, and by this means a certain amount of water is evaporated in the precipitating tank, and thus brings up the degree of concentration of the solution to 400 milligrammes (6 grains) per litre (1¾ pint). The boring that furnishes the steam is 63 metres (210 feet) in depth, and the temperature of the water in the tank is maintained at 94° Cent. (202° Fah.). This solution, which has a specific gravity of 11° of Baumé's areometer, is conducted in the usual manner to the evaporators, which are constructed in a similar manner to those at Lardarello, the water being kept at a temperature of 76° Cent. (169° Fah.), by the steam from "Il foro Filippo," and having traversed the entire length of the pans is received into the boiler at the lower end with a specific gravity of from 12° to 50° Baumé, and is crystallized, dried, and packed in the usual manner. The evaporating shed contains three rows of evaporators, 64 metres (207 feet) in length by 3 metres (10 feet) in width. The production is about 26 kilos. 200 grammes per day (57·64 lbs.).

PRESCRIPTIONS.

The following paragraphs are taken from a paper contributed to the *American Journal of Pharmacy* for October, by Mr. M. S. Bidwell, in which several points of interest to physicians and pharmacists are discussed:—

"The first question is on the ownership of the prescription or recipe. To which one of the three parties concerned—physician, patient, and pharmacist—does it belong? It may aid us in answering this question fairly, if we first consider what a prescription is, illustrating it by an example. Suppose a physician to visit consecutively three patients. To the first he may say: 'You need some beef tea: get a piece of the round to make it of. I will give you a note to the butcher, explaining what kind you want.' To the second he might say: 'Send your boy to my office with this memorandum, and the student there will give you the necessary medicine'—the memorandum directing, perhaps, to give him four pills out of the box on the lower shelf, or any other instructions that the student will understand. To the third he gives a recipe, in the usual form, directing the pharmacist into whose hands it may come to put up a certain mixture for the patient's cough. Now, is it not evident that the note to the butcher, the memorandum to the student, and the recipe to the pharmacist are precisely analogous? We may therefore define a prescription to be a confidential letter from a physician to a pharmacist, instructing him to dispense certain medicines according to directions given. So far, then, as these two parties are concerned, it would follow the same rule as any other letter—the recipient being entitled to its custody, but having no right to publish it, or use it in any similar way, without the consent of the writer.

"But there is a third party in this case—the patient; and by universal custom, sanctioned by law wherever the statutes touch the subject, he is entitled to a copy of the document. The original should remain in the hands of the pharmacist, for reasons which need not here be given.

"The second point concerns what is called the renewal of prescriptions, or, more properly, dispensing the same medicines repeatedly on the same recipe. This very common practice has been extensively denounced by physicians, on various grounds, but with a curious and complete disregard of the party most directly interested—the customer. Their usual line of argument on this subject, if carried out to its legitimate conclusion, would forbid the sale or use of any medicines unless by the express direction of a doctor. They say, with perfect truth, that much harm is done by ignorant prescribing, and by unqualified persons dosing themselves and others with medicines whose powers they do not understand. Therefore, the government, or the druggist, or somebody, should henceforth decree that this be done no more. They do not apply or state it so broadly as this; but the principle is evidently the same, whether the medicine were originally prescribed by a physician or not; so that it is here stated in its broadest form, in which shape it is a clear *reductio ad absurdum*. The evident answer, if any answer is needed, would be, that in America every one is presumed to be able to judge for himself, and must be allowed to take his own risk if he will. Any interference on the part of the druggist would naturally be resented as an impertinence, and be met by the just remark that it was none of his business.

"In the more special case immediately under our notice, the reduplication of the prescription cannot be prevented, even if both physician and druggist should try to do so. The patient is entitled to a copy, and can, of course, have the same medicine put up from that, or from a copy of that. Even physicians will hardly claim that no druggist should ever put up any medicine that any physician had ever prescribed!

"There is another complaint often made by physicians, which is, in some respects, the reverse of this, viz., that prescriptions are often 'stolen' from them by druggists and others, and used to their disadvantage, by curing their patients without their help. In the former case, the ostensible ground of complaint was that the recipe might injure the patient; in this, the danger is that it may benefit him, without bringing any pay to the physician. Poor doctor! So long as he does not get his fee, he is equally dissatisfied, whether the patient grows better or worse! Well, it is hard if a man has got hold of an efficient formula for a certain class of cases, to have Tom, Dick, and Harry steal his thunder, and cure just as many and just as well as he can himself, and perhaps make a great flourish about it too. But our pity for him will be lessened if we remember that he himself owes almost all of his prescriptions to others; and it will be reduced to a minimum by the reflection that it is only by the free contribution of many workers that medical science (or any other) can ever be built up. The only way a man can keep others from knowing what he does is to keep it a secret, which, if generally carried out, would throw us back into the dark ages. At the same time it must not be forgotten that, if any one wishes to monopolize any item of knowledge, he has a perfect right to do so, and no one can justly complain of such a course, though no one can admire it.

"Briefly to recapitulate:—

"1. A prescription is a confidential letter from a physician to a pharmacist, the latter having the right of custody, but not the right to make it public. The patient, being an interested party, has a right to a copy.

"2. The druggist's business is to furnish whatever medicines the customer wants, whether prescribed by a doctor or not, the patient taking his own risk.

"3. The physician, like any other scientific man, should be liberal in communicating what he originates, because most of his own knowledge is derived from others; and in this way only can science be advanced. But this obligation is ethical, not legal; something to be desired and recommended, not enforced."

The author concludes with a disclaimer of countenancing the practice of "prescribing across the counter," or prescribing by any unqualified person, which he considers to be a nuisance in the drug business that every intelligent and fair-minded pharmacist will endeavour to abate.

A CHEAP AND CONVENIENT GALVANIC BATTERY, ADAPTED FOR WEAK BUT CONTINUOUS CURRENTS.*

BY W. SYMONS, F.C.S.

For the experiments referred to in a previous paper † a battery was thus constructed. Zinc plates are cut out of ordinary rolled zinc two inches square, with a narrow projection at top of three-fourths of an inch. Doubled round each side of these plates, and fastened with thread, are half-inch strips of fustian, or other stout cloth. Copper wire No. 20 or 24 is wound tight round each plate at intervals of one-eighth of an inch, leaving one and a quarter inch of wire free at the top. The fustian keeps the wire from touching the zinc. A series of ten of these plates, with blocks of wood about an inch thick between each pair, are tied tight together, and the projecting copper wire of each soldered to the next zinc, the terminal zinc and copper having each a wire projecting eight or ten inches. A thin strip of dry deal, of a suitable length, and about an inch and a quarter wide, has nailed round it narrow strips of deal a quarter of an inch square, so as to make a shallow tray. Into this tray is melted a mixture of shellac and resin. While this is still soft the ten pairs of plates, tied together with the blocks of wood, are turned upon it, so that the soldered joints are buried in the resin. In a minute or two the resin is hard, the blocks of wood can be removed, and the ten pairs of plates will be firmly fixed in the wooden tray, the terminal wires being passed through it.

The cells are made of extra stout tinfoil, or thin sheet lead, about three inches long, two and a half inches deep, and five-eighths of an inch wide, double folding the joint at the side, and also at the bottom, after neatly folding in the sides. The top sides of the cells are doubled back over thin strips of wood, about three and a half inches long. These metal cells can be more easily made on a wooden mould than paper ones, and when dipped into a mixture of melted wax and paraffin are impervious to liquids.

These cells are supported and effectually isolated by the projecting slips of wood resting on varnished strips of wood, placed across a box. Forty pairs of such cells may thus be placed in a deal box, 13 inches by 11 inches, and can be easily arranged by binding screws into a series of 10, 20, or 40 pairs, according to the requirements for quantity or intensity.

The liquid used has been one ounce of common salt in 25oz. of water, and by occasionally replenishing the cells with a liquid of half this strength a nearly uniform current may be kept up for weeks or months. But as there is a gradual accumulation of an insoluble salt, I have more recently tried a dilute solution of zinc chloride.

From 20 to 40 pairs of this battery have been sufficient for the experiment described; but as they can be so easily constructed, and when placed in a series of boxes occupy so little space, any experimentalist may soon furnish himself with a series of some hundreds, to serve as a water battery. Of course, when the zinc plates are worn out, the trays and wires can be used again with fresh plates.

Barnstaple, July 27, 1874.

COMMON WILD FLOWERS CONSIDERED IN RELATION TO INSECTS.‡

At the close of the last century, Conrad Sprengel published a most valuable work on Flowers, in which he pointed out that their forms and colours, their scent,

* Paper read before the British Association at Belfast, September, 1874.

† See before, p. 325.

‡ Abstract of an Address by Sir John Lubbock, Bart., F.R.S., at the Belfast meeting of the British Association.

honey, and general structure, have reference to the visits of insects, which are of importance to Flowers in transferring the pollen from the stamens to the pistil. Sprengel's admirable work, however, did not attract the attention it deserved, and remained comparatively unknown until Mr. Darwin devoted himself to the subject. Our illustrious countryman was the first to perceive that insects are of importance to Flowers, not only in transferring the pollen from the stamens to the pistil, but in transferring it from the stamens of one flower to the pistil of another. Sprengel had, indeed, observed in more than one instance that this was the case; but he did not appreciate the importance of the fact. Mr. Darwin's remarkable memoir on Primulæ was published in 1862. In that treatise the importance of cross-fertilization was conclusively proved, and he has since illustrated the same rule by a number of researches on Orchids, Linum, Lythrum, and a variety of other plants. The new impulse thus given to the study of Flowers has been followed up in this country by Hooker, Ogle, Bennett, and other naturalists, and on the Continent by Axell, Delpino, Hildebrand, and especially by Dr. H. Müller, who has published an excellent work on the subject, bringing together the observations of others, and adding to them an immense number of his own.

Every one, indeed, knows how important flowers are to insects; but it is only recently that we have realized, on the other hand, how important, indeed, how necessary, insects are to flowers.

That the colour of the corolla has reference to the visits of insects is well shown by the case of flowers which—as, for instance, the ray or outside florets of *Centaurea cyanus*—contain neither stamens nor pistils, and serve, therefore, mainly, and it would seem entirely, to render the flower-head more conspicuous. Again, night flowers are white, that they may be seen, while their near allies are coloured; thus *Lychnis vespertina*, as its name denotes, is an evening flower, and is white; while *Lychnis diurna*, which flowers by day, is red. The calyx, moreover, is usually green; but when the position of the flower is such that it is much exposed, it becomes brightly coloured, as, for instance, in the berberry or larkspur.

If it be objected that this is *assuming* the existence of these gradual modifications, it may be replied that it is not here purposed to discuss the doctrine of natural selection. The reader, however, may be reminded that Mr. Darwin's theory is based on the following considerations:—(1) That no two animals or plants in nature are identical in all respects; (2) That the offspring tend to inherit the peculiarities of their parents; (3) That of those which come into existence only a certain number reach maturity; (4) That those which are, on the whole, best adapted to the circumstances in which they are placed, are most likely to leave descendants.

No one of these statements is, or can be, disputed, and they seem fully to justify the conclusions which Mr. Darwin has deduced from them, though not all those which have been attributed to him by his opponents.

Now, applying these considerations to flowers, if it is an advantage to them that they should be visited by insects (and that this is so will presently be shown), then it is obvious that those flowers which, either by their larger size, or brighter colour, or sweeter scent, or greater richness in honey, are most attractive to insects, will, *cæteris paribus*, have an advantage in the struggle for existence, and be most likely to perpetuate their race.

In most flowers, indeed, the pistil is surrounded by a row of stamens, and it would at first sight seem a very simple matter that the pollen of the latter should fall on the former. This, in fact, does happen in many cases, but in others, from the structure of the flower, it is impossible. In these cases the transference of the pollen from one flower to another is effected principally either by the wind or by insects. Wind-fertilized flowers, however, as those of birches, poplars, and grasses, are never brightly coloured, and are, indeed, not popularly recognized as flowers.

Every one, however, who has watched flowers, and seen how assiduously they are visited by insects for the sake of honey, will admit that they must often transfer pollen from the stamens to the pistil; in many cases from the stamens to the pistil of the same flower; but in others from the stamens of one flower to the pistil of another. This we will call cross-fertilization.

The importance of this cross-fertilization has been fully proved by experiment. Every breeder of sheep or cattle knows the necessity of avoiding "in and in" breeding, and it is no less necessary to avoid it in the case of plants.

We will now pass to the consideration of the means by which self-fertilization is checked, and cross-impregnation is effected, in plants. In some cases the pollen is simply wind-borne, in others it is carried by insects. These are attracted partly by the pollen itself, partly by the honey; while the bright colour and the scent serve to indicate the spot where the pollen and honey are to be found. The calyx, which is not generally brightly coloured, probably serves as a protection to the honey, and tends to prevent bees and other insects from obtaining access to it by force.

It is an almost invariable rule that wind-impregnated flowers are inconspicuous, but the reverse does not hold good; and there are many flowers, which, though habitually visited by insects, are not brightly coloured. In some cases flowers make up by their numbers for the want of individual conspicuousness. In others the insects are attracted by scent; indeed, as has already been mentioned, the scent, as well as the colour of flowers, has no doubt been greatly developed through natural selection as an attraction to insects. In confirmation of this it is stated that when insects are excluded, the blossoms last longer than is otherwise the case; that when flowers are once fertilized, the corolla soon drops off, its functions being performed. But though bright colours and strong odours are sufficient to attract the attention of insects, something more is required. Flowers, however sweet-smelling or beautiful, would not be visited by insects unless they had some more substantial advantages to offer. These advantages are the pollen and the honey; though it has been suggested by Sprengel that some flowers beguile insects by holding out the expectation of honey which does not really exist, just as some animals repel their enemies by resembling other species which are either dangerous or disagreeable.

In our ordinary flowers the transference of the pollen from one flower to another is effected by insects, and the colour, the scent, and the honey are the attractions by which the visits of insects are secured. That the beauty of flowers is useful in attracting insects is shown, moreover, by those genera in which we find species which vary very much in size and beauty. Thus we have two common species of Mallow (*Malva sylvestris* and *Malva rotundifolia*), which agree closely with one another in other respects, but of which the former is much larger than the latter, and Sir John showed that the former is dependent for its fertilization on the visits of insects, while the latter is capable of fertilizing itself. To show that this is no isolated case, he brought forward several other examples of the same fact, especially one very striking one in the genus *Geranium*. *Geranium pratense* is one of our larger species, and is nearly twice as large as *Geranium pyrenaicum*, which again is nearly twice as large as *G. molle*, while *G. molle* itself is considerably larger than *G. pusilum*. Now, in *G. pratense* the pistil does not come to maturity till all the stamens have ripened and shed their pollen, and the flower, therefore, is absolutely dependent on insects for its fertilization. In the second, *G. pyrenaicum*, some of the stamens have shed their pollen before the pistil is mature, but the visits of insects are, therefore, not absolutely necessary. In *G. molle* the pistil matures still earlier; while lastly, in *G. pusilum*, it matures even before the stamens. Here, therefore, we have a complete series, and the more the flower is dependent on insects the longer it has become. As already mentioned, the self-fertilization of flowers is guarded against in various ways, Very frequently the stamens and pistils do not ripen at the same time.

In other cases the pistil ripens before the stamens. Thus the Aristolochia has a flower which consists of a long tube with a narrow opening closed by stiff hairs, which point backwards, so that it much resembles an ordinary eel-trap. Small flies enter the tube in search of honey, which from the direction of the hairs they can do easily, though, on the other hand, from the same cause, it is impossible for them to return. Thus they are imprisoned in the flower; gradually, however, the pistil passes maturity, the stamens ripen and shed their pollen, by which the flies get thoroughly dusted. Then the hairs of the tube shrivel up and release the prisoners, which carry the pollen to another flower.

Again, in the common Arum we find a somewhat similar mode of fertilization. The well-known green leaf encloses a central pillar, which supports a number of pistils near the base, and of anthers somewhat higher. Now, in this case nothing would at first sight seem easier or more natural than that the pollen from the anthers should fall on and fertilize the pistils. This, however, is not what occurs. The pistils mature before the anthers, and by the time the pollen is shed have become incapable of fertilization. It is impossible, therefore, that the plant should fertilize itself. Nor can the pollen be carried by wind. When it is shed it drops to the bottom of the tube, where it is so effectually sheltered that nothing short of a hurricane could dislodge it; and although the Arum is common enough, still the chances against any of the pollen so dislodged being blown into the tube of another plant would be immense.

As, however, in Aristolochia, so also in Arum, small insects which, attracted by the showy central spadix, the prospect of shelter or of honey, enter the tube while the stigmas are mature, find themselves imprisoned, as the fringe of hairs, while permitting their entrance, prevents them from returning. After a while, however, the period of maturity of the stigmas is over, and each secretes a drop of honey, thus repaying the insects for their captivity. The anthers then ripen and shed their pollen, which falls on and adheres to the insects. Then the hairs gradually shrivel up and set the insects free, carrying the pollen with them, so that those which then visit another plant can hardly fail to deposit some of it on the stigmas. Sometimes more than a hundred small flies will be found in a single Arum. In these two cases there is obviously a great advantage in the fact that the stigmas arrive at maturity before the anthers. Generally, the advantage is the other way, and the stamens ripen before the pistil.

Of this the common so-called Nasturtium (*Tropæolum*) is an interesting case. It produces much honey, which is situated in a long hollow spur. The flowers are much visited by insects, which thrust their proboscides down the spur in search of honey. When the flower first opens neither the stamens nor pistils are mature, and they are all turned slightly downwards. Very soon, however, one of the stamens turns upwards, so as to stand just at the entrance to the spur, and in such a position that the under side of the proboscis of any insect wanting the honey almost inevitably rubs against it and carries off some of the pollen. One after another the eight stamens raise themselves and occupy this position, a process which occupies several days, after which they turn down again to the original position, and the pistil in its turn raises itself to the mouth of the tube. From this beautiful arrangement it is evident that the bees and other insects visiting this flower for the sake of the honey inevitably dust themselves with pollen from the younger flowers, and transfer it to the pistil of the older ones.

Attention must now be called in more detail to some of our common wild flowers, in order to show how beautifully they are adapted to profit by the visits of insects, and how the various parts are arranged so as to favour not only the transfer of pollen from one flower to another, but also its deposition on that part of the pistil which is especially prepared for its reception. Wherever the pistil projects beyond the stamens, it is obvious that a bee alighting on the flower would come in contact first with the former and subsequently with the latter. In flying from flower to flower, therefore, she would generally fertilize each with the pollen of one which had been previously visited.

In few flowers is the adaptation of the various parts to the visits of insects more clearly and beautifully shown than in the common white dead nettle (*Lamium album*). The honey occupies the lower contracted portion of the tube, and is protected from the rain by the arched upper lip and by a thick rim of hairs. Above the narrower lower portion the tube expands and throws out a broad lip, which serves as an alighting place for large bees, while the length of the narrow tube prevents the smaller species from obtaining access to the honey, which would be injurious to the flower, as it would remove the source of attraction for the bees, without effecting the object in view. At the base of the tube, moreover, there is a ring of hairs, which prevent small insects from creeping down the tube and so getting at the honey. *Lamium*, in fact, like so many of our other wildflowers, is especially adapted for humble-bees. They alight on the lower lip, which projects at the side so as to afford them a leverage by means of which they may press the proboscis down the tube to the honey; while, on the other hand, the arched upper lip, in its size, form, and position, is admirably adapted not only as a protection against rain, but also to prevent the anthers and pistil from yielding too easily to the pressure of the insect, and thus to ensure that it presses the pollen which it has brought from other flowers against the pistil, and, on the other hand, carries away a fresh supply from the anthers.

If we compare Lamium with other flowers we shall see how great a saving is effected by this beautiful adaptation. The stamens are reduced to four, the stigma almost to a point. How great a contrast with the pines and their clouds of pollen, or even with such a flower as the Nymphæa, where the visits of insects are secured, but the transference of the pollen to the stigma is, so to say, accidental! Yet the fertilization of Lamium is not less effectually secured than in either of these.

From the position of the pistil, which hangs down below the anthers, the bee comes in contact with the former before touching the latter, and, consequently, generally deposits upon the stigma pollen from another flower. The small processes on each side of the lower lip are the rudiments of the lateral leaves with which the ancestors of the Lamium were provided. Thus, then, we can see how every part of this flower is either—like the size and shape of the arched upper lip, the relative position of the pistils and anthers, the length and narrowness of the tube, the size and position of the lower lip, the ring of hairs, and the honey—adapted to ensure the transference by bees of pollen from one another, or, like the minute lateral points, is an inheritance from more highly developed organs of ancestors. Sir John Lubbock then called attention to certain species of the genus Salvia, a form allied to the dead nettle, but in which the back of the bee does not come in contact with its arched upper lips, and consequently does not touch the anthers in their natural position. They possess, however, a very curious tinge point, so arranged that the proboscis of the bee, in passing down the tube, presses one arm of a lever, and thus brings the other, which bears the anther, down on to the back of the bee.

The common heaths (*Erica tetralix* and *Erica cinerea*) present another very ingenious arrangement. In *Erica tetralix* (the cross-leaved heath), for instance, the flower is in the form of a bell, which hangs with its mouth downwards, and is almost closed by the pistil, which represents the clapper. The stamens are eight in number, and each terminates in two cells, which divergslightly, and have at their lower end an oval opening; but, though this opening is at the lower end of the anther cells, the pollen cannot fall out, because each cell, just where the opening is situated, touches the next anther cell, and the series of anthers thus form a circle surrounding the pistil, and not far from the centre of the bell. Each anther cell also sends out a long process, which thus form a series of spokes standing out from the circle of anthers. Under these circumstances, a bee endeavouring to suck the honey from the nectary cannot fail, firstly, to bring its head in contact with the viscid stigma, and thus to deposit upon it any pollen derived from a previous visit; and secondly, in thrusting its proboscis up the bell, it inevitably comes in contact with one of the anther processes, which acts like a lever, and dislocates the whole chain of anther cells, when a shower of pollen falls from the open cells on the head of the bee. In many cases the effect of the colouring and scent is greatly enhanced by the association of several flowers in one bunch or raceme, as, for instance, in the wild hyacinth, the lilac, and other familiar instances in the great family of Umbelliferæ.

This arrangement is still further taken advantage of, as in the common wild chervil (*Chærophyllum sylvestre*). In this group the honey is not, as in the flowers just described, situated at the bottom of a tube, but is exposed, and is therefore accessible to a great variety of small insects. The union of the florets into a head is, moreover, not only of advantage in rendering them more conspicuous, but also effects a considerable saving of time, as it enables the insects to visit a given number of flowers more rapidly, and, consequently, renders their fertilization more certain than if they had stood singly. The self-fertilization which, in small flowers such as these, would otherwise naturally occur, is provided against by the fact that the stamens ripen before the pistil, and the latter is not mature until the former have shed their pollen; so that the flowers cannot, therefore, fertilize themselves in some cases, as, for instance, in *Myrrhis*. The flowers of one head are all, firstly, in the male condition, and subsequently in that with mature stigmas, none of them arriving at the second stage until they have all passed through the first. It will be seen that in these florets the petals are not symmetrical, the outer ones being considerably larger than the others, and in many umbellifers the florets themselves, on the outer edge of the bunch, or umbel, are considerably larger than the minor ones. This distinction is carried still further in the composite, where also the florets are so closely packed that the whole umbel is commonly—though, of course, incorrectly—spoken of as a flower. For instance, the heads of the common daisy are not, strictly speaking, flowers, but bunches of flowers closely packed together on a common base or receptacle. The advantages of this arrangement are, first, that the flowers become much more conspicuous than would be the case if they were arranged singly; secondly, that the facility with which the honey is obtained renders them more attractive to insects; thirdly, that the visits of the insects are more likely to be effectual, since the chances are that an insect which once alights touches several, if not many, florets. In the large white daisy the flower-heads consist of an outer row of female florets, in which the tubular carolla terminates on the outer side in a white leaf or ray, which, doubtless, is useful in making the flower conspicuous. The minor florets are also tubular, but are small, yellow, and without rays; each of these florets is furnished with stamens as well as a pistil. The stamens are united on their minor sides, so as to form a closed tube, within which the pistil lies; they ripen before the pistil, and the pollen is discharged into the upper end of the tube above the head of the pistil. When the flower opens the pollen is already ripe, and fills the upper part of the stamen tube. The pistil, however, also continues to elongate, and at length pushes the pollen against the upper end of the tube, which gives way, and thus the pollen is forced out of the tube. The pistil itself terminates in two branches, which at first are pressed closely to one another, each terminating in a brush of hairs; the style elongates, the brush of hair sweeps the pollen cleanly out of the tube, and it is then soon removed by insects. When the pistil has attained its full length the two branches open and curve downwards, so as to expose the stigmatic surfaces, which had previously been pressed closely to one another, and thus protected from the action of the pollen. From this arrangement it is obvious that any insect alighting on the flower-head of the chrysanthemum would dust its under side with the pollen of the younger flowers, which then could not fail to be brought into contact with the stigmatic surfaces of the older ones. As the expansion of the flowers begins at the outside, and thence extends to the centre, it is plain that the pollen of any given flower cannot be used to fertilize one situated on its inner side; consequently, if the outer row of florets produced pollen, it would, in the great majority of cases, be wasted. These florets, therefore, do not produce pollen, while the saving thus effected enables them to produce a larger corolla. It is also interesting to observe that, in these outer flowers, the branches of the pistil do not possess the terminal brush of hair, which, in the absence of pollen, would be useless. In other composites, as in the marigold, while the ray flowers produce no pollen, the disk flowers develop no stigmas. In this case the pistil of the ray flower does not require or possess the terminal brush of hairs, as there is no pollen to be swept out. The central flowers, on the other hand, though they develop no stigmas, require a pistil in order to force the pollen out of the anther tube; hence the pistil is present. This alteration of the function of the pistil is extremely curious. In the flowers hitherto described, while the several species offer the most diverse arrangements, we have met with no differences within the limits of the same species, excepting those dependent upon sex.

Perhaps no group of flowers offers more remarkable adaptations than the orchids, which have been so admirably described by Mr. Darwin. As an illustration of our English species, the common early purple orchis (*Orchis mascula*), may be taken as being one of the commonest, if not the commonest, species, and a fair example of some of the remainder, which, however, differ in many interesting and important points. In the case of *Catasetum*, one of the *Vandeæ*, which, as Mr. Darwin says, "are the most remarkable of all orchids," the pollinia and the stigmatic surfaces are in different flowers; hence it is certain that the former must be carried to the latter by the agency of insects. The pollinia, moreover, are furnished with a viscid disc, as in orchis; but from the large size of the flower and the position of the honey, the insect has no inducement to approach, and, in fact, does not touch the viscid disc. The flower, however, is endowed with a peculiar sensitiveness, and actually throws the pollinium at the insect. Mr. Darwin irritated one of these flowers in Sir John Lubbock's presence; the pollinium was thrown nearly three feet, when it struck and adhered to the pane of a window. This irritability, however, is confined to certain parts of the flower.

In one other tropical flower, the very curious *Marcgraavia nepenthoides*. The flowers are disdosed in a circle, and beneath them are suspended some pitcher-like vessels, which secrete a sweetish liquid, and thus attract numerous insects. These again bring birds, which can hardly fail to brush against the flowers, and thus convey the pollen from one to the other.

Some species possess flowers of two or more kinds, which sometimes, as in the violet, are adapted to different conditions, but more frequently are so constituted as to insure cross-fertilization. In some of the violets (*V. odorata*, *canina*, etc.), besides the blue flowers with which we are all so familiar, but which produce very little seed, there are other autumnal flowers almost without petals and stamens, and which indeed have none of the appearance of true flowers, but in which the seeds are produced.

(To be continued.)

The Pharmaceutical Journal.

SATURDAY, OCTOBER 31, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal to MESSRS. CHURCHILL, *New Burlington Street, London, W Envelopes indorsed " Pharm. Journ."*

CRAMMING AND LEARNING.

ONE addition to the elements of the "education" turmoil consequent upon the enlargement of the area of examinations during recent years has been the application of an ugly name to an uglier practice, in so loose a manner that its definition by different persons varies through almost an infinity of gradations. "Cram," which has no classic pedigree in the dictionary of JOHNSON or WEBSTER, appears to be equally destitute of a settled character, and whilst in some quarters hands are held up in pious horror at the bare mention of it, a few of our correspondents not only claim acquaintance with it, but assert that it is a reputable and valuable friend. Of course, when a barbarous, slangy nomenclature is adopted, no one can say with authority what is the exact meaning to be attached to it. But in the application of this word to pseudo-study, there is probably more than a chance resemblance to the name of a practice that comes into vogue in the poultry-yard about this time of the year; for, to some minds at least, the word indicates in both instances a gorging to repletion, but in neither case a healthy normal assimilation.

The vigorous denunciation by Mr. GILES of a something called "cram" has, we hope, been endorsed by the majority of all pharmacists who have heard or read it. That there is, however, a minority who disagree with it, is evidenced by several letters we have received; but these letters show that the disagreement arises sometimes from a failure to perceive truly the position taken by Mr. GILES and others in this matter, and sometimes from a failure on the part of the writers to perceive their own position in regard to it.

Let us deal with the misunderstandings in the order in which they are stated. Some of our correspondents assert that this is a mere battle of schools. One is of opinion that in Mr. GILES's remarks he had a particular school in view, and that their effect has been to "drag a well-known name through the mire." Another asserts that the object of this and similar condemnations is to obtain a larger number of students in the Society's school. What Mr. GILES may mean beyond what he said we are not in a position to affirm; what he has said is on record, and can be appealed to. So also can the history of the Pharmaceutical Society in respect to education. And we venture to say that in any case where a shadow of obloquy has fallen upon school or pupil it has been perceptible to the outside world only in proportion as the one has advertised its willingness to provide methodical assistance in baffling the examiners, or the other has sought out and adopted such methods. In fact, Mr. SCHACHT's warning to the British Pharmaceutical Conference in Brighton, that cramming was quite as possible at Bloomsbury Square as elsewhere, was only an anticipation of Mr. GILES's words when he said, "Every school is, of course, subject to be abused by candidates who—caring only for the specious pretensions of a certificate—enter for these short periods, and it is only when the school wilfully lends itself to the abuse that it can fairly be held responsible." As to the imputation of interested motives, it is not worth notice, except to remark that if pharmaceutical education were the reality desired by Mr. GILES, not only would all existing real schools of pharmacy be filled, but others would have to be created.

The stigmatizing of the votary of "cram" as an accomplice in a fraud is resented by those who look upon examination as an evil imposed upon them by an arbitrary government, and, blind to its real object, seek to overcome it in the most ready way, as well as by others who assert that all study is "cram." Any argument we could offer to the former would probably be thrown away; we can only hope that they will in time acquire clearer views. With the latter we have more sympathy. Their right to consider cram and study as synonymous terms, if so it pleases them, we cannot deny; but we do deny that what is considered by them to be study is more than "cram." One correspondent, urging this point, curiously, but quite unwittingly, illustrates the difference we would draw between them. He says that, having passed the Preliminary examination in a country town, he immediately purchased a work on botany and commenced a systematic study of it, getting up early in the morning and searching the lanes and woods for specimens, in order better to understand the subject. Here we have all the materials for a truly scientific education; the corroboration of statements made in books by personal observation and experience. But chemistry did not fare so well at this gentleman's hands. A manual was purchased, about forty or fifty pages, more or less, read, some of it twice over—not a word, however, about experiments —and then he "got into a complete fog," from which he does not appear yet to have emerged. Nor will he do so until he studies chemistry after the same fashion as he did botany.

Committing to memory a variety of information differs widely from the practical application of it. A knowledge of scientific principles is valuable to the pharmacist, as a pharmacist, only in so far as it enables him to understand and systematize the experience which he obtains in the every-day life of the pharmacy.

But it is the scientific knowledge and practical experience combined that are demanded for the safety of the public and the welfare of the calling. Knowing, therefore, how much more easily the former is simulated than the latter, the Board of Examiners seek by the new regulations to render more practical—not to increase the stringency of—the examinations. No higher standard is set up than before, only its attainment is questioned by a more searching test. Mr. GILES and many others rightly conceive that a compulsory curriculum of two or three years would help to abolish the scandal of contracts to fit men, within a few weeks, to foil the examiners. Whether this assistance may be required, or whether the new regulations will prove to be sufficient to the task, we heartily wish a speedy success to these efforts to stamp out a system, by whatever name it may be called, which has really engendered fraud by assisting men knowingly to pass for what they were not!

GODFREY'S LABORATORY, MAIDEN LANE. 1680.

THIS old building, to which is attached some traditionary interest, has at length been converted into a sacred edifice in communion with the Church of Rome, and bears the name of Corpus Christi. The ground plan of the laboratory is left unchanged, no re-arrangement having been required. A church porch replaces the ancient doorway, while the side entrance to the right is gained by the removal of the furnaces erected for the Hon. ROBERT BOYLE, in order to work out his phosphorus experiments.

They have long fallen into disuse; only one, having been of late years employed in making various charcoals. The carmine boiler stood where the font has been erected: further on, a wooden beam stretched lengthways down the aisle, and served as the spring for a huge iron pestle. Next came the still and condensing vats, and an unwieldy looking but most serviceable screw-press. The fireplaces for the stills and furnaces were admirably contrived, and the secret of their construction was never successfully imitated in their re-setting. They were under the superintendence of an old man, who, though not great in chemical theories, had an unrivalled talent in the art of lighting fires, using the least possible material and avoiding smoke. When a local act compelled the introduction of a smoke-consuming contrivance his mind was much aggrieved at the (to him) useless innovation. One day a fire broke out on the premises, which did no extensive damage; but it quietly licked up some rows of ancient glass vessels, used at that date in pharmacy, which might have been included amongst the treasures of the Antiquarian Society.

The high altar and the choir occupy the space once known as the *Carmine Room*, where two of the processes of its manufacture were carried on, and where the pigment was finally kept in stock. The light still falls in the most favourable direction: the aids conducive to the production of a fine colour being a free current of dry air, indirect sunshine, and tolerably hot weather. Carefully to be avoided was a close, muggy morning, when the whole *make* would be lost.

Amongst the historical curiosities of the Laboratory was an application made to supply the *Anointing Oil* at the coronation of his Majesty GEORGE the FOURTH.

The following is the extract from the *Times*, June 8, 1821:—

"The next petition was from the Chymists, Southampton Street, Strand, praying that they might be allowed to prepare and supply the oil to be used in anointing his MAJESTY at the coronation, as their house had performed that office at the coronation of GEORGE 3rd. The petition was returned to the applicant on the ground that the Court had no jurisdiction in the case, and he was told to apply to the office of the LORD CHAMBERLAIN."

Modern appliances have of necessity disturbed the reign of cumbrous apparatus; but few of the congregation who listened to the Archbishop of WESTMINSTER at the Consecration Service were aware of the strange transmutation that had taken place.

The Phenix is left undisturbed in its old position in Southampton Street, where it has ample leisure to muse over the mutability of human things.

THE CULTIVATION OF MEDICINAL PLANTS ON RAILWAY BANKS.

A LETTER has been forwarded to the *Garden* by Mr. JAMES M'NAB, of the Royal Gardens, Edinburgh, upon a topic which has often been discussed by railway travellers, namely, the turning of railway banks and slopes to a more profitable account. Among other suggestions he points out that many plants suitable for the production of essential oils might be successfully cultivated upon them, such as the peppermint, spearmint, lavender, thyme, and balm, and in many places the hundred-leaved and damask roses. Other plants, some more immediately connected with the healing art, which he thinks could be profitably grown in such localities, are the chamomile (*Anthemis nobilis*), horehound (*Marrubium vulgare*), rue (*Ruta graveolens*), tansy (*Tanacetum vulgare*), the wormwoods (*Artemisia Abrotanum* and *A. Absinthium*), elecampane (*Inula Helenium*), wild convolvulus (*Convolvulus sepium* and *C. arvensis*), henbane (*Hyoscyamus niger*), belladonna or deadly nightshade (*Atropa belladonna*), monkshood (*Aconitum napellus*), bittersweet (*Solanum dulcamara*), foxglove (*Digitalis purpurea*), the great mullein (*Verbascum thapsus*), and the chicory (*Cichorium Intybus*). The wake-robin (*Arum maculatum*) would also succeed well, and its tubers might be found to yield a superior starch to that produced by the plants grown in woods, which is its native habitation.

OLIBANUM.

THE *Boswellia* trees, yielding gum olibanum, are so common in the Central Provinces of India that it is estimated 10,000 tons annually could be procured from Chanda and the Nerbudda valley alone.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first general meeting of the twenty-sixth session was held at the Royal Institution, on Thursday evening, the 22nd inst., the President, Mr. Alfred H. Mason, F.C.S., in the chair.

The minutes of the preceding meeting were read and confirmed.

Mr. Richard Evans was elected a member, and Mr. E. Jones was elected an associate of the Association.

The following donations were announced:—Specimen of Stearopten, of Chinese Oil of Peppermint, to the museum from Mr. Farries, London; *The New York Druggists' Circular*, January to October, from Mr. Mercer, Montreal; current numbers of the *Pharmaceutical Journal;* and Dr. Muter's 'Introduction to Pharmaceutical and Medical Chemistry,' from the President.

The question box was opened, and several questions were discussed, relating to Chilian Iodine, Jaborandi, Croton Chloral, etc. Several members took exception to an article in the *Chemist and Druggist* respecting the affairs of the Association, stating that the statements contained therein were inaccurate.

The President then delivered his

Inaugural Address.

"It has been the usual custom to commence the work of our session with an inaugural address from the presidential chair. It has pleased your Council to honour me with the privilege this evening; but when I look back to those addresses which have on similar occasions emanated from my predecessors, I cannot help feeling misgivings of a most serious nature as to my ability to follow in their footsteps, without discredit to myself and disappointment to you; therefore, in anticipation, I must ask your indulgence for any shortcomings, and proceed to inaugurate the twenty-sixth session of the Association.

"Having for our object the advancement of chemical and pharmaceutical science, we are essentially an educational body, composed of various elements—I trust seeking the same end; instituted by its founders as an offspring chiefly to second the efforts of the Pharmaceutical Society of Great Britain in raising the condition of British pharmacy and improving the status of the British pharmacist. I do not, therefore, purpose troubling you with any *résumé* upon the merits or otherwise of the Adulteration Act (further than that in my opinion it has been productive of great gain to the analytical chemist, and of considerable benefit to the general public), or upon the desirability of early closing, uniform prices, the snare of patent medicine stamps, etc., and similar questions which have been raised in this room, as I am convinced that, whenever we have allowed trade questions to be brought forward, they have always been productive of evil, and led to differences which I trust, gentlemen, have long ere this passed into oblivion. We are not a trade body, nor can we legally permit such discussions. I say this because I believe it is the opinion of some of our members that we should admit such.

"Admitting that we are an educational body, let us for a few moments consider the advantages of a pharmaceutical education. Pharmacy is not a trade. Pharmacy is an art and a science; and this fact becomes more and more evident as the rapid advancement of science determines the equally rapid progress of pharmacy, in common with the industrial arts. The basis of every exact science is observation; the experience gained thereby leads, on the one hand, to reasoning power, and to the establishment of fundamental principles, and, on the other hand, to the generalization of scientific truths. It is a guide to synthesis, as well as to the opposite method of investigation, analysis.

"The selection of all medicinal substances of unexceptional purity; the recognition of all adulterations and impurities; the manufacture of chemical and pharmaceutical preparations by the formulas of the Pharmacopœia; the collection, drying, and preservation of all crude drugs, their proper comminution and exhaustion by maceration or displacement, the compounding of physicians' prescriptions with correctness and nicety, belong to the art of pharmacy. While the knowledge of the reasons why a prescription should be prepared in a particular way, of the causes which affect the success of percolation, of the influence of heat, moisture, atmosphere, age, etc., upon drugs, of the development in plants and their parts, of the active principle or principles; of the causes of success or failure in carrying out any process or manipulation connected with pharmacy, properly belong to science in its bearing upon pharmacy.

"Further, in the study of pharmacy we find ourselves aided by natural philosophy, chemistry, botany, zoology, geology, and mineralogy. Time this evening will only permit me to enlarge upon chemistry, as most important in its influence upon the development of medicine, and the selection of curative agents; the science which deals with the relations of the various kinds of matter to each other, the labours of whose students are influencing the investigations of every other branch of natural science, are felt in numerous trades and manufactures, and are of the utmost importance in their bearings upon every-day life. It is not many years ago when the brines left after the separation of common salt from saline spring or sea water were without value; now immense quantities of bromine are recovered from it, and that element has not only become an indispensable article in many of the arts, but medicine has also appropriated it for the cure of disease. Its compounds, too, which in our time were but chemical curiosities, are now to be found in every dispensary, and are prescribed by every physician. The oily and tarry products of our gas factories were supposed for a long time to be valueless, until chemistry converted some of them into brilliant colours of every shade and hue, which are now employed in dying fabrics and various commodities. The mother liquor from soap was thought to be a waste product, until uses were found for its most important constituents, and glycerine is now such an indispensable agent in pharmacy, medicine, the arts, and the household, that we may well wonder how civilized mankind could get along without an article which, in its natural combination, is daily employed everywhere.

"Owing to the investigations of chemistry, many articles of materia medica have been displaced, and others, doubtless, sooner or later, will pass into deserved obscurity.

"Acidulous fruit, the sorrels, and other acidulous drugs are gradually being retired from active service, since the pure acids, upon which their virtues depend, are being prepared in large quantities, and in condition fit for long preservation. Since the vegetable alkaloids have been discovered, and the processes for their manufacture perfected, their employment in medicine has gradually increased, and, as a matter of consequence, the corresponding increase in the use of the crude material has been prevented. But chemistry is not content even with such results. By processes of substitution it furnishes new remedies of valuable medicinal properties, which will probably take the place of older remedies. Chloral, croton chloral, and monobromated camphor are instances, among others, of such innovation. Already chemistry has prepared a new way for replacing time-honoured medicines, by offering apo-derivatives of alkaloids, at least one of which, apomorphia, promises not only to hold its place against various mineral emetics, but threatens even to supersede such a valuable emetic as ipecacuanha, and to render fears groundless should the plant be gradually exterminated.

"Too true it is that, whilst your Council are desirous to do all in their power to attain the objects of our Association by assisting students in chemistry and pharmacy, of late their provision has fallen off, not from any want of material, but owing to a lack of sympathy from those for-whom such classes are formed. But is this Society singular in this respect? No! Kindred associations, and even the parent Society herself, groan beneath the weight of 'cram,' against which there has been of late so just an outcry, but which will probably exist so long as examination is made the only test of knowledge. There are hopes, however, of better days.

"It was my privilege to hear the able address delivered to the students at Bloomsbury Square at the commencement of the present session. I may take exception to some of its precepts, but I commend its careful perusal to every student in pharmacy.

"We have plenty of evidence from great authorities, such as Lord Derby, Disraeli, Gladstone, and others, that compulsory examination, taken alone, is quite insufficient to produce a demand for real education, and we must admit that examination, *per se*, never was, and probably never can be, a thorough test of competency. But the evil is not found among pharmacists only; analytical and consulting chemists are also in the same category, and it is painful to hear of analytical chemists offering to perform analyses for fees which cannot cover the outlay of pure reagents, and asking clients the significant question, whether they are buying or selling the sample which they bring for analysis.

"Permit me to call your attention to the experience of Professor Huxley on examination. He says, 'Examination—thorough, searching examination—is an indispensable accompaniment of teaching; but I am almost inclined to commit myself to the very heterodox proposition that it is a necessary evil. I am a very old examiner, having for some twenty years past been occupied with examinations on a considerable scale, of all sorts and conditions of men and women, too—from the boys and girls of elementary schools to the candidates for honours and fellowships in the universities. I will not say that in this case, as in so many others, the adage that familiarity breeds contempt holds good; but my admiration for the existing system of examination and its products does not wax warmer as I see more of it. Examination, like fire, is a good servant but a bad master; and there seems to me to be some danger of its becoming our master. I by no means stand alone in this opinion. Experienced friends of mine do not hesitate to say that students whose career they watch appear to them to become deteriorated by the constant effort to pass this or that examination, just as we hear of men's brains becoming affected by the daily necessity of catching a train. They work to pass, not to know; and outraged science takes her revenge. They do pass, and they don't know. I have passed sundry examinations in my time, not without credit, and I confess I am ashamed to think how very little real knowledge underlay the torrent of stuff which I was able to pour out on paper. In fact, that which examination, as ordinarily conducted, tests, is simply a man's power of work under stimulus, and his capacity for rapidly and clearly producing that which, for the time, he has got into his mind.' He further says:

"'No doubt, a great deal is to be done by the careful selection of examiners and by the copious introduction of practical work to remove the evils inseparable from examination; but under the best of circumstances I believe that examination will remain but an imperfect test of knowledge, and a still more imperfect test of capacity, while it tells nothing about a man's power as an investigator.'

"In olden days an indenture of apprenticeship (which in our case probably necessitated a good premium as well), duly endorsed by the master with a satisfactory reference as to character, etc., during the period of probation, was a *sine quâ non* qualification to secure a position as a qualified journeyman; and what did that amount to but a compulsory education. Is it too much for those who organize pharmaceutical examinations that they should require a curriculum of compulsory education, as has been suggested, evidence of a three years' pupilage, or apprenticeship, and, further, evidence of having attended lectures in a recognized school of pharmacy?

"Admitting, therefore, our own responsibility in this matter, as an Association, let us see what means we employ to meet the case. Besides our School of Pharmacy, which has done good work, and which I trust will be well supported during the present session, we have, during the period of our existence, accumulated a collection of standard works upon chemistry, botany, pharmacy, materia medica, etc., which makes our library almost complete. Further, we duly receive various journals published at home and abroad; we have raised a museum, which is well stocked with specimens, and these are for the free use of our members and associates. We also offer opportunities for younger men to come here and take part in discussions, and afterwards to come round here, face the audience, and give us the benefit of their investigations by reading papers, etc. Further, we have the advantage of receiving valuable papers, etc., from those of greater experience. Bacon says: 'He that questioneth much shall learn much.'

"With every possible desire to avoid egotism, I address you this evening as living evidence of the advantages of our Association. Some ten or eleven years ago I was admitted as a member of our body, and under favourable circumstances, for, as an assistant, I was not expected to sacrifice the enjoyment of the evening out 'once a week,' but my principal generously placed the opportunity to attend these meetings at my disposal. I well remember that I used to attend to the duties most religiously, take notes, and on my return home write out a *résumé* of the paper I had heard read. Here I read my maiden scientific paper, if I may so term it, and now, unworthy, I confess, I am honoured with your presidency, comparatively young. To all my younger brethren permit me to say, 'Do thou likewise.'

"During the recess the meetings of the British Association and of the British Pharmaceutical Conference have been held. The value of such associations cannot be overestimated, for in this way men of similar purpose are brought into personal contact, and an intimacy springs up which leads to an interchange of the results of experiments, besides an interest in watching the workings of those with whose faces we are familiar. Can we have greater proof of the necessary part which purely abstract chemistry bears on pharmaceutical manipulation than the thoroughly worked out communication on the chemistry of cinchona bark, by Dr. Vrij, and, passing other important papers, we cannot over-estimate the value of the four papers on hydrocyanic acid. However unstable that medicine may be, its therapeutic value is too securely planted in the mind of the medical profession to be ever lightly abandoned. Here, therefore, comes one of the special duties of the pharmacist, to exhibit this remedy in a form in which its unstable composition is least liable to change. The wonderful influence of glycerine in the preservation of hydrocyanic acid is remarkable. I would only urge, in testing these experiments, the absolute necessity of using Price's glycerine, foreign glycerine not being of sufficient chemical purity to ensure satisfactory results. Certainly these practical researches have considerably advanced our knowledge of the subject.

"The administration of phosphorus is another subject probably suitable for the further investigation of the pharmacist. Here again glycerine combined with alcohol is advantageous, and such a solution, suggested by Mr. Williams, is now being largely prescribed by London medical men.

"In these days of high pressure the lack of novelties is evident. Occasionally our expectations are raised by the appearance of a condurango bark, and we are led to wonder how it is that the marvellous properties of such a medicine disappear in transit to England? From the Brazils, *viâ* Paris, a few months ago, we received 'Guarana,' now a recognized medicine of value, and we are looking for some confirmation from the same source of the supposed virtues of 'Jaborandi,' described as an energetic diaphoretic and sialagogue. Eucalyptus globulus has proved useful in therapeutics, and as a fever destroyer, and the perseverance of Mr. Baildon in reviving Cortex Rhamni Frangulæ deserves our appreciation.

"Chemical investigation will ever result in new discoveries, and the most interesting of late is probably the conversion of coniferin into the active principle of vanilla, by Messrs. Tiemann and Haarmann, of Berlin. In their communication the authors commence by describing the preparation of coniferin ($C_{16}H_{22}O_8$), the raw material used being the juice from recently felled and barked pine trees in spring time. This is split up by digestion at a gentle heat, with a small quantity of emulsion. The vanillin thus obtained ($C_8H_8O_3$) is at first inodorous, but in the course of time acquires a faint odour of vanilla. The chemical world are indebted to these gentlemen for their announcement. In former days there seemed to be a kind of fatality about great discoveries. Men stumbled across valuable ideas, and learned, too soon, important truths, which lay dormant, only to be appreciated by the world after their departure.

"The history of arts and sciences offers many examples. Faraday, in 1825, found benzol in the tarry residues of gas-works, but that illustrious chemist obtained, whilst living, neither fame nor profit for his discovery, which remained buried in the archives of the Royal Institution until the attention of the scientific and industrial world was drawn to the chemical properties of the substance, almost forty years later on.

"Before concluding, permit me to say a word or two about the session just inaugurated. Your Council have arranged for a course of lectures on Inorganic Chemistry, Preparation of Chemical Products used in Pharmacy, and Qualitative and Volumetric Analysis, to be delivered by Mr. Edward Davies, F.C.S., Lecturer on Experimental Physics, Queen's College, etc., assisted by Mr. M'Gowan, late Young's Burser, Andersonian University, Glasgow. The course will extend over six months, should a sufficient number of students apply for admission, ten being the minimum. It has been thought more to the interest of students and the convenience of employers to hold the classes from nine to ten a.m. In the name of our Council, let me entreat of you young men to avail yourselves of the opportunities we offer you. These lectures are such as will, with diligence on your part, materially assist you in your further studies. You are probably aware that the examinations of the Pharmaceutical Society have been altered, not made more stringent, but more practical. The Council propose to grant certificates of attendance to those who merit them, and, further, Mr. Davies has kindly offered a prize for the best student during the session. Professor Attfield has also consented to send down some examination papers, and report the results, and upon those results I propose to place prizes at the disposal of those who rank first and second. These prizes are offered, not as an inducement to attend the classes, but as an appreciation of your desire to promote the interests of the Liverpool School of Pharmacy, by your diligence and ability. To all those masters who have apprentices in this town I would say, 'Beware of your responsibility, and encourage your students to join these classes.'

"Your Council proposes to vary the business of the Association by making the alternate meeting of a conversational character, by which means members may be brought more into personal contact. Any objects of interest may be exhibited and explained, difficulties which arise in manipulation may perhaps be solved, difficult and extraordinary prescriptions might be discussed, and I would suggest entire freedom in the matter. Once a month we propose to have papers on scientific subjects, and I have already promises which I trust will make our session a very successful one. I rely upon your unanimous and individual support. Let each one of us feel that upon himself—his own work—the success of the Association depends.

"Homer says :—

'By mutual confidence, mutual aid,
Great deeds are done, and great advances made.'

May this be our experience!

"Gentlemen,—My best energies are at your service. I sincerely thank you for the honour that has been conferred upon me. I thank you for your kind attention this evening, and I trust the twenty-sixth session of our Association may, if possible, be more successful than any of the preceding."

Mr. Abraham moved that the thanks of the meeting be given to the President for his excellent address, with all of which he thought he could cordially agree, except that he did not concur with the President and others in thinking that candidates should not be admitted to the examinations of the Pharmaceutical Society unless they had passed through a prescribed curriculum. He appreciated very highly systematic instruction by lectures, demonstrations, and practical courses of instruction, but he thought that such restrictions would not only tend to discourage private study, but would work an injustice in the case of those who had not the means of pursuing a regular course of study. The argument, he understood, was that examinations would not sufficiently test the qualifications of candidates. He could not believe this. It might be difficult or impossible to test them during the minutes now devoted to the purpose; but why not, if needful, extend the time? The India Civil Service examinations sometimes occupied more than a week, and ours might be equally extended rather than adopt the alternative proposed, and refuse examination to a self-educated man. Let the examination be adapted to the occasion, and he believed they would answer their purpose.

Dr. Cook seconded the motion, but said he had listened to the address with a great deal of pain and sorrow. It was much *too pharmaceutical*, and he did not agree that the Association was of the nature described. He had, a few days previously, devoted some time in going over the books, etc., of the Association, and he found that whenever the pharmaceutical element had been brought so much to the front—and the Society was under pharmaceutical *régime*—it had not prospered. His opinion was that it was a strictly scientific chemical society, and if properly guided in this spirit it would prosper. The President had alluded to Professor Faraday and his discovery of benzol; if such men had confined themselves to pharmaceutical chemistry these discoveries would have never been made.

Mr. Edward, F.C.S., Vice-President, supported the motion. He did not agree with Dr. Cook, that the objects, etc., of the Association had been erroneously brought before them, and, speaking as a scientific chemist, he considered that they could not overrate the value of the study of pharmaceutical chemistry. He had much pleasure in agreeing with the views of the President.

Mr. Martin Murphy, F.C.S., supported the motion, and said it was generally understood that a Chemists' Association did not necessarily consist of scientific analytical chemists, but of chemists and druggists as well.

Mr. Shaw supported the motion, and thought Dr. Cook to be in error. He said the Society in London had given the matter much consideration; he agreed with the views of the President.

Mr. J. T. Armstrong, F.C.S., agreed with Dr. Cook. He had much pleasure in putting the motion to the meeting, which was carried with acclamation.

The President thanked the members for their compliments. He was not surprised to hear Dr. Cook's objection. He, however, hoped before the session closed that gentlemen would be satisfied with the work done, for he had received promises of several papers of a scientific nature from chemists of eminence, and the intermediate evenings might be appropriated to pharmacy proper, which subject had rather than otherwise been neglected by them of late. The next lecture would be on "the atomic theory," by Mr. Siebold, of Manchester, editor of the 'Year Book of Pharmacy.'

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Carbon and certain Compounds of Carbon.*

BY PROFESSOR BARFF.

In a recent course of Cantor Lectures, delivered before the Society of Arts, Professor Barff treated of carbon and certain compounds of carbon, especially with a view of making suggestions for the improvement of heating, lighting, filtering, and other apparatus. We propose to give in the following abstract the chief points of those lectures.

Introducing the subject by some remarks upon the importance of the application of scientific principles in all arrangements for heating and lighting, he said he could not conceive how any one could arrive properly at the conception of any apparatus for the production or economizing of heat, or for lighting or for any other kindred purpose unless he had a knowledge of the scientific principles involved in his invention. For example, if he does not know the way in which heat passes from a hot body to the bodies surrounding it, how can he know how to economize that heat? Thus, a person puts a fire into an iron grate with an iron back, and with iron all round it. Now, what does this act imply? He puts in and about his fireplace something which takes away almost all the heat, or a large portion of the heat which is being generated, and that is evidently a mistake; therefore, it is necessary that a person who is thinking about heating apparatuses, should know something about the conducting power of the materials he has to deal with. We know now by experience that a fire-clay back to a grate is of great advantage, and throws out much of the heat into the room. Again, advice has been given that people should mix chalk with their coals in order to produce greater warmth. That is a very good plan, no doubt, but by mixing chalk with coal not an iota more heat is generated from the coal than before; you do not make heat, you cannot produce it. The substance which is burned yields a certain amount of heat, and no more; it can be drawn out slowly or quickly, but only a certain amount of heat will be got from its combustion. This may be illustrated by the burning of charcoal in oxygen, and comparing the rapid combustion with the slow combustion which the same carbon undergoes when in the form of a piece of wood, or leaves, or sawdust, it is allowed gradually to decay and oxidize slowly through a long period of time; the quantity of heat given off in that slow combustion of the carbon would be exactly the same as the quantity given off in the more rapid burning of the charcoal. No skill on earth could make it give out more heat on its combustion than it had given out; the time in which it is being given out can be regulated, but you cannot regulate the quantity if all be burnt. Take a Bunsen burner; there is a certain amount of heat being given off, but if the hand be put to it it will feel very little heat indeed. But if into that flame a solid substance be put and made red hot it will feel much more heat. The solid substance does not generate heat; it only acts as a conservator or reservoir, and gives it out slowly, so that if a number of Bunsen burners were burnt in a room which it was wanted to warm, a certain amount of heat would be evolved in the combustion of the carbon and hydrogen in the gas, but the room would not be made comfortably warm; such a source of heat would not be sufficient for comfort. But if we take some solid matter that will not burn away, such as asbestos or solid lime, and put that into these burners and get it red hot, then we do get the heat, not increased in quality, but only regulated as to its radiation, that is to say, regulated as to the quantity that is given out from the source of heat in a given space of time. This principle is applied to grates, fireplaces being arranged with lumps of asbestos and gas burners under them. When the gas is first turned on, little or no heat is felt from it because the flame does not radiate the heat in such a way as to make it appreciable to the senses; but with the same quantity of gas burning, as the asbestos gets red hot, according to some it will give out as much heat and be as comfortable as a common coal fire.

From these remarks it will be seen how important it is that anyone who is going to invent an apparatus for heating should know, at least, these principles, namely, how heat is absorbed, how it is given out, and how it is conducted. The lecturer said he had heard of a person who had for years devoted himself to making stoves, grates, and so forth, but when the question of how it is the smoke goes up a chimney was mentioned, he expressed himself quite ignorant of the principle. That might seem strange, but that gentleman was not in the wrong according to his own views, for he entered the business many years ago, and formerly it was not thought necessary that persons should have scientific knowledge to do things involving scientific principles. It is only of late years that we have begun to appreciate the value of scientific knowledge. Thus, Dr. Graham, in his introductory lecture, almost felt it necessary to apologize to his audience of brewers for talking of science, when they had been going on for so many years making good beer without it. But it is most important, as far as possible, to get to the bottom of scientific principles. By the system of education which is being adopted now throughout the land boys are being taught science most admirably, and the rising generation will most of them know something about scientific principles.

Carbon appears largely distributed in nature. In the air we breathe there is a great quantity of carbonic acid, the quantity of which is being sustained continually by our breathing, for we are perpetually breathing it out, and it is being perpetually absorbed by plants. Again, there is chalk, which is carbonate of lime, there is also dolomite, which is carbonate of lime and magnesia, and there is also magnesite and other carbonates existing in nature, so that we have large quantities of carbon existing in the form of carbonates.

The lecturer then, by various experiments, illustrated the difference which there is in the heating of substances out of contact with air, and heating them in contact with air. If wood be perfectly charred, and the action then allowed to go on in the presence of air, the charcoal will gradually disappear as a gas, formed of the charcoal combined with the oxygen of the air; and nothing then will be left behind but the several substances contained in the wood which are not destroyed by the action of heat, *i.e.*, the ash. When any organic substance is heated out of contact with air, we speak of the process as one of destructive distillation, by which is meant that the substance, as such, is destroyed, that it is not resolved into its ultimate constituents; that is to say, that the elements which compose it are not separated from one another, but that it is broken up into compounds more or less simple than the elements formed in the substance itself. For example, when wood is destroyed as wood, we speak of it as destructive distillation, and if the products were collected we should find that they contained the same elements that the wood contained, only in different chemical combinations.

Carbon exists in all organic substances, but it exists in some in such proportions that when they are exposed to the action of this destructive distillation, no residue of charcoal is left behind at all; the charcoal all passes away

* Abstract of a course of Cantor Lectures, delivered before the Society of Arts.

along with the other elements, forming new substances. An instance of this is a substance which is obtained from the sorrel plant, which also exists in rhubarb and other acid plants; a potash salt, commonly called binoxalate of potash, from which can be obtained oxalic acid, which contains carbon, oxygen, and hydrogen in such proportions that the carbon and oxygen unite together to form two gases, carbonic acid and carbonic oxide, and the hydrogen unites with the remainder of the oxygen to form water. The consequence is that when oxalic acid is heated no carbon is left behind.

It is necessary, therefore, to bear in mind that there are these two classes of bodies; those which yield a quantity of carbon after the other substances have been thrown off, and those which yield none, because these will have to be alluded to again when speaking about coal.

Charcoal is very porous, and if thrown into water it will float. But charcoal is heavier than water, for, although it will float, it is for the same reason that an ironclad will float. Fill the ironclad with water, and down it goes; but it is very difficult to fill charcoal with water. If anybody could get over that difficulty, he might make a very large fortune, because then he would be able to impregnate wood through and through with a solution of a silicate which would render it thoroughly uninflammable.

Charcoal has a wonderful power of absorbing gases, and that has been explained by different persons in different ways. The knowledge of this fact was applied years ago, and was described by Dr. Stenhouse, the inventor of charcoal respirators. They are arranged to cover the nose and mouth, so that persons may breathe through them in a poisonous atmosphere without being affected by the poison. Those respirators contain charcoal in a state of fine division, and there is no doubt they are very useful. A quantity were made for the troops sent out on the Ashantee expedition, so that the soldiers might wear them when exposed at night to the malarious influences of that marshy country. Whether they were used or not the lecturer did not know, but he said there was no doubt whatever that charcoal will prevent the introduction into the lungs of very poisonous gases in small quantities. He had heard it said that a person could breathe an atmosphere of prussic acid or of strong ammonia, but he should say, from his experience with ammonia, that it was impossible. Still, it was no reason because the respirator would fail in these extreme cases why, where the quantity was great, that it should not be particularly useful to persons attending the sick bed of persons suffering from contagious or infectious diseases. Another substance which has the same power as wood charcoal, only to a much greater extent, and is much more energetic and active, is spongy platinum.

Another principle which animal charcoal possesses—and of extreme importance in a domestic point of view—is that of deodorizing tainted meat and absorbing bad smells. If putrid flesh be covered with animal charcoal all the bad smell will be absolutely destroyed. The charcoal absorbs the bad smell, and, more than that, it oxidizes the bad gases, burning them up, so that the substances which produce the bad smells are not absorbed to remain in the charcoal, but they are oxidised and burnt most effectually. This action has been spoken of as catalytic, a long name used with regard to substances which, although not acted upon themselves, yet have the power of producing chemical action in other bodies. But it appeared as if an action quite different from that goes on —an oxidating process—not through the absorbent power of the charcoal necessarily, but because there is an oxidation of the charcoal going on there slowly, although the charcoal is not a substance readily and easily oxidised, and that induces the oxidation of the escaping effluvia. Whether that view is right or not the lecturer said he did not know; he merely stated it as held by some.

Now, to what use can this be applied? Often it happens, particularly in the summer time, that a leg of mut ton, sent home on the Saturday night from the butcher and wanted for roasting on Sunday, during a muggy night will become tainted, and, in fact, entirely spoilt for the Sunday dinner. Now, it is quite certain that the process of decomposition that has gone on during the night has not been enough to render the meat unwholesome. There is no great putrefaction taking place—speaking of putrefaction in the ordinary acceptation of the term. If that meat be covered with charcoal, and left all night, the smell either will not occur or else it will be done away with. But one would not like to cover it with charcoal and so blacken the meat. Have a cupboard made, or a small box, and line it with charcoal in powder, and that will answer the same purpose. Make a muslin bag about three inches every way smaller than the box, drop it into the box, and then fill the space all round with animal charcoal. If the lid of the box is treated in a similar manner animal charcoal will be all round the meat, and on putting the meat in if it is not tainted it will not get tainted, and if it has become tainted it will lose that tainted smell.

Animal charcoal has the power of decolorizing and deodorizing water, and destroying the substances which give it colour and smell.

Charcoal filters can be easily obtained. But if it is not wished to buy one, some animal charcoal may be mixed with sand, and it will act perfectly in an ordinary filter.

Graphite is made into crucibles for melting cast iron and other substances, and they are employed for that purpose because graphite will stand such a tremendously high temperature without igniting with the oxygen of the air.

One of the properties of this substance is that when reduced to fine powder it can be pressed into hard blocks, which are as hard, if not harder, than the lumps of natural graphite. Those blocks can be cut into strips and made into lead pencils. Formerly, the best pencils were made from native lumps of blacklead, but now the best are made from the compressed graphite.

Another kind of graphite is formed in the manufacture of coal gas. When the retorts are heated to a high temperature, and the evolution of coal gas is going on rapidly, there is a deposition from the coal gas of carbon in the upper part of the retorts which forms that particular substance which is called artificial graphite; it is a sort of coke, for coke is an artificial graphite, just as is the charcoal or the amorphous carbon got by the heating of wood. The uses to which this substance is applied are various. For instance, pieces are used for the Bunsen's battery, instead of the platinum, which is used in Grove's battery, and is much less expensive, though it is liable to certain defects. Carbon points are made out of that sort of coal graphite, and used for the electric light. They are placed on the terminals of the battery point to point, the negative at the top and the positive underneath. It is extremely interesting to notice that one of these points makes no mark upon a piece of white paper, or hardly any, but the other one marks like a blacklead pencil. The negative terminal is apparently unaffected, but in the positive the charcoal, or graphite, is converted into a substance similar to natural plumbago. Some years ago some experiments were performed with a battery of 600 cells, and it was found that carbon could be volatilized; at least it was thought so. In a vacuous space the operator brought the points together, and found that a sort of brownish vapour was given off, and that crystals of a substance like graphite were formed on the side of a glass vessel. He then got some perfectly pure sugar charcoal, attached a crystal to the negative pole and one to the positive pole, and connected them with a battery. He found that when the galvanic current had passed for some time particles aggregated together, and formed a mass similar to plumbago. At the positive pole this conversion of graphite into plumbago takes place, and at the negative pole there is next to no change at all. That is a most interesting fact.

The diamond is the purest form of carbon we possess. This native graphite is formed in crystals, and also without crystallization in a form called amorphous. It is the amorphous which is adapted for making pencils. But it also occurs in the crystalline form, and crystallizes in what is called hexagonal bodies belonging to the rhombohedral system. The diamond crystallizes in octohedra, but not always, for some diamonds crystallize in dodecahedrons, and in others the faces of the dodecahedrons have three separate facets. The diamond is not pure carbon, though it is the purest form in which we have it, for when a diamond is burned in oxygen a residue is left behind—an ash—and that ash strangely has a sort of cellular structure. The diamond is usually of a bright light colour, and it refracts light wonderfully, being excessively dense. Its density is 3·55, or $3\frac{1}{2}$ times as dense as water, and it is the hardest substance in nature. For that reason it is used for cutting glass, but a cut diamond will not do for that purpose ; the natural crystalline point must be used, otherwise the cut will be very jagged. Sometimes diamonds are pink, sometimes green, and some are perfectly black and opaque.

(*To be continued.*)

Parliamentary and Law Proceedings.

Infringement of the Pharmacy Act.

In the Bloomsbury County Court, before George Lake Russell, Esq., Judge, on Thursday, October 22, George Day, of 3, Farringdon Road, contractor, was sued for a penalty, according to the particulars, which were as follows—"To amount of penalty incurred by the defendant, in selling or keeping open shop, for retailing, dispensing, or compounding poisons, or a poison, contrary to the provisions of the Pharmacy Act, 1868 (31 and 32 Vict. cap. 121), £ 5."

Mr. Flux appeared for the plaintiff, and the defendant appeared in person.

Mr. Flux, in opening the case, said that the defendant was sued under the 15th clause of the Act of Parliament, in respect of a penalty incurred by him consequent on the compounding of a medicine which contained prussic acid as an ingredient, and on the sale of a packet of oxalic acid.

The defendant objected to the jurisdiction of the Court. He produced a paper, showing that, in respect of the sale of oxalic acid, he had been convicted before a magistrate, and contended that he could not be twice placed in any peril in respect of one sale, and that, as regards the sale of prussic acid, a letter, written to him by Mr. Flux, had conveyed the impression that it would not be relied upon in this case.

Mr. Flux said that his letter had not been intended to convey the impression to which the defendant referred, but that, having regard to the defendant's statement, he (Mr. Flux) would elect not to proceed upon the sale of prussic acid, but to take a stand upon the sale of oxalic acid, and rely upon his view of the Act of Parliament, which was that by the sale of oxalic acid, improperly labelled, the defendant had been rightly convicted by a magistrate under the 17th section, and that by the same sale of oxalic acid, he (not being a registered chemist and druggist) had incurred a penalty under the 15th section, which was rightly sued upon in that action ; so that the conviction before the magistrate was no bar in the action.

The Judge reserved for consideration the point raised by the defendant, and directed that the evidence should be proceeded with.

Mr. Ward, examined by Mr. Flux, proved, that on Tuesday, August 4, he, at the shop No. 4, Farringdon Road, asked for a small quantity of oxalic acid, and that he was supplied with the packet produced, labelled, "Oxalic Acid. Poison. H. W. Howse, Operative and Analytical Chemist, 29th, Exmouth Street, Clerkenwell, one door from Farringdon Road," and paid one penny for it. That he afterwards handed the packet, in the condition in which he had received it, to Dr. Redwood ; and, that the defendant had in his presence admitted himself to be the proprietor of the shop, and that several letters produced were in his (defendant's) handwriting.

Dr. Redwood, examined, proved that he had received from the last witness the packet produced; that he had analyzed the contents, and found them to consist of oxalic acid.

The witnesses were cross-examined at length by the defendant, without any material fact being elicited.

The defendant was then sworn, and addressed the Court, contending that he was right in keeping open the shop, although he was a contractor, and not a chemist and druggist ; he having purchased the business of Mr. Howse, and had that person's authority to use his name in the business. He said that he had employed a manager whom he believed to be competent to conduct the business ; and he had sustained loss in the conduct of the business, and he urged that he ought to be protected from the harsh proceedings of the Pharmaceutical Society, who had become his prosecutors and persecutors, on the information of persons whose names ought to be discovered and held up to public scorn.

William West, called by the defendant, proved, that he had been many years employed in the business of a chemist and druggist, and was competent to conduct it, and did conduct the defendant's business on the occasion when the sale complained of had been effected, and until about a month ago, when he left the defendant's employment. That the defendant had left to him full discretion, and never taken any personal part in the conduct of the business, and that, after the conviction in the police court, no sale was, so far as known to him, made at the shop.

Cross-examined by Mr. Flux, witness admitted that he did not leave defendant's employ until about a month ago, and that the shop had continued open until that time, but he could not say whether it still continued open. Could say that a brass plate, which bore the words "Howse, Chemist," had been removed, but declined to say whether the labels bearing the words "Howse, Chemist," had or not continued in use. Admitted that a letter, dated May 22, 1874, and purporting to be signed by the defendant as G. Day, was in his (witness's) handwriting, and signed by him. And would also say, that a paper, handed by him in the 7th August, on the occasion of his calling on Mr. Flux, was in his handwriting. Denied that the letter and paper were written with the knowledge or sanction of the defendant, or that he had informed defendant of them. On the witness being asked whether he was, or ever had been, on the Register of Chemists and Druggists, the Judge said that he might decline to answer, on the ground that his answer might tend to criminate himself, and thereupon he declined to answer the question.

Mr. Flux pointed the Judge's attention to the fact that, whether the witness had or not been on the Register of Chemists and Druggists could be ascertained by reference to the printed Register, in the hands of the Court, and he referred to it as showing that the witness was not a duly qualified chemist and druggist. He also read the correspondence to prove that the defendant had not been used harshly, and that, on the contrary, all proper consideration had been shown to him, and he had persistently and defiantly offended.

The Judge said: I have considered the Act of Parliament, and am of opinion that it is a beneficial Act, passed in the interests and for the protection of the public ; and that this is not a case which should lead me to strain the law in the defendant's favour. I have considered the 15th and 17th sections of the Act, and am of opinion that the conviction at the police court was for a distinct received offence, under the 17th section, viz., for "Selling oxalic acid without affixing the name and address of the seller to it;" and that the defendant is properly sued for a separate penalty, consequent on an offence under the 15th section, although the two offences were committed at the one time, and by the one act. The defendant appears to be an educated man and a man of intelligence, and one who ought to have known and respected this law, which regulates the sale of poisons, and is intended to protect the public against the many fatal and other accidents which might arise if the sale of poisons was not regulated. I am the more careful to say this because I see many poor people here, and they may be persons who cannot distinguish between the duly qualified chemist and one who is not so qualified. I have read the correspondence, and I think that by the letter of October 10, the defendant was defiant; and I agree also in the observation made in reply, that it is not expedient that the names of parties who may give information regarding offenders under this Act of Parliament should be disclosed. I have therefore to give a verdict in favour of the plaintiffs. The defendant will have to pay the £5 penalty, with the costs of these proceedings.

The Defendant: I have no doubt that your Honour has given a conscientious judgment, but I ask that a case may be stated upon which I can take the decision of the Court of Queen's Bench.

The Judge: Mr. Flux, have you any objection?

Mr. Flux: Not the least.

The Judge: You can have a case stated, if, on further consideration, you think it desirable.

Reviews.

An Elementary Treatise on Practical Chemistry and Qualitative Inorganic Analysis; specially adapted for use in the Laboratories of Schools and Colleges, and by Beginners. By Frank Clowes, B.Sc. Lond., &c. London: J. and A. Churchill, 1874. 8vo, pp. 327. *7s. 6d.*

It seems almost incredible that with the crowd of text-books on practical chemistry already in existence, bearing the familiar names of Fresenius, Harcourt, Galloway, Odling, Roscoe, Valentin, and others, there should be any sign of a demand for a new one on the same subject. Such, however, appears to be the case, the largely increased development of science-teaching in the public and other schools of the country constituting, we presume, the *raison d'être* of the volume we have before us.

So lately as ten or fifteen years ago there were probably not half a dozen schools in the kingdom where experimental science was cultivated as a recognized part of the general curriculum, and certainly the number of school laboratories in existence could not have exceeded two or three. In those days the science-teaching in schools was conducted almost exclusively by a set of peripatetic lecturers, who went the round of the establishments within a given circuit, and who were looked upon by both masters and pupils as a sort of supernumerary whose services would be assessed at about the same fee as those of the dancing master, but who occupied in the estimation of both a position of far less respect and importance.

But all this is changed nowadays, and chemistry and natural philosophy run neck-and-neck with Greek grammar and Latin prose composition.

Even in the old days, however, there was a certain number of schools where science was regarded with no disfavour. Foremost amongst these was the College at Queenwood, in Hampshire, an establishment to which we shall be doing no serious injustice when we say that it owes its excellent reputation mainly to the teaching of physical science, which for many years past has formed a prominent and characteristic part of the scheme of education pursued within its walls, and in no small degree to the names—Tyndall, Frankland, Debus—of some of the teachers who have laboured there. The author of the book before us is at the present time "Science Master" in Queenwood College, and he tells us that his work was commenced in order to supply a course of practical chemistry to his own classes. If we are to understand from this that the contents of the book represent without exaggeration the nature and extent of the practical work done by the boys in the Queenwood laboratory, we may fairly congratulate Mr. Clowes on the creditable character of their performances.

The standard of proficiency in natural science to which boys having Latin and Greek, history and geography, arithmetic and algebra, and half a dozen other things besides their play to think about, may be brought by systematic training under a teacher who knows how to make his subject attractive, is certainly surprising.

This book is specially adapted for school use, and will probably find its way into the hands of many teachers who have the instruction of classes of young students. It is a book which, faithfully used, will do more than teach a boy to recognize in a mere mechanical way a few metals and salts; it will encourage and, indeed, compel him to use all his faculties of observation and reason, and go very far towards giving him a sound and practical knowledge of the chief elements and their inorganic compounds. The plan of the book is not very different from that of several others of similar pretensions, but its details present advantages which will recommend it strongly.

The first section is devoted to experiments illustrating the methods of preparation and properties of some important gases and other bodies. Section II. gives directions for making and using apparatus required in chemical analysis, and in both these sections it will be found that every article mentioned is of so simple a character and so minutely described that any intelligent boy can prepare the whole for himself without appealing to the teacher for more than occasional assistance or advice.

In the sections devoted to qualitative analysis "Tables of Differences" are introduced, which contain for each analytical group of radicles a summary of the difference of behaviour exhibited by its several members with the same reagents. This plan was employed in nearly the same way in Galloway's 'Manual of Qualitative Analysis,' and to him, we believe, belongs the credit of having originally introduced this most instructive system.

So far as we can discover, the tests and methods of separation recommended by the author have been judiciously selected. Full instructions are also given with regard to the entry of the results of analysis in the note-book. For young students especially there is nothing to which greater attention should be paid than the systematic record of every experiment performed, with a full account of the inferences to be drawn from the result. At first this practice consumes a little time and seems tedious, but long experience of its beneficial effects has convinced us that the student should never be permitted to neglect it. Mr. Clowes, we notice, uses the word "acid" in places where we should consider "acid radicle," or some phrase of that sort, more strictly accurate. The qualitative reactions commonly employed for the detection of chlorides, nitrates, and sulphates must surely be applicable to *all* salts which bear those names. Moreover, there is a positive error in the statement made in the book among the examples (pp. 193—199), that a certain white crystalline substance given for analysis contains Pb and HNO_3, that a second white solid contains Ca and H_3PO_4, a third Ca and $H_2C_2O_4$, and, again, that sulphate of barium contains barium and sulphuric acid, H_2SO_4. The chief objection to such lapses is that they require explanation from the teacher.

It is to be regretted that a work otherwise so carefully compiled and so truly commendable should exhibit more than a few blemishes in its literary character. No extraordinary command of English is required to correct such phrases as "at first commenced," "place into" a spoon or jar, or "each such," a screeching alliteration which occurs several times. The author will soon have an opportunity of altering all this. We recommend him to make a good use of it when it comes, and in the next edition to avoid errata.

Handbook of Natural Philosophy: Hydrostatics and Pneumatics. By Dionysius Lardner, D.C.L. New edition. Edited by Benjamin Loewy, F.R.A.S. London: Lockwood and Co. 1874.

The popular treatises of Dr. Lardner have done good service in time past in bringing the truths of science within the reach of general readers in a pleasant and not too severe form. Professedly popular, they were still accurate as far as they went, so that the reader who afterwards extended his study beyond their limits found that he had little or nothing to unlearn. Hence, remembering the good qualities of the early editions, we welcomed this new issue under the care of Mr. Loewy.

The volume which formerly treated of Hydrostatics, Pneumatics, and Heat has been divided, the last subject being reserved for a separate volume, and the book now before us devoted to the two former. This allows room for a considerable increase of matter, the work extending to 344 pages instead of 236, as formerly.

The general arrangement of the contents has not been materially changed, although to a large extent re-written, the alterations consisting for the most part of the expansion of the theoretical portions and the addition of new matter rendered necessary by modern scientific progress.

After considering the fundamental properties of liquids, the laws of liquid pressure, the equilibrium of immersed and floating bodies, and the application of these laws in a multitude of contrivances, such as the hydraulic press, embankments, levels, wells, ships, instruments for determining specific gravities, etc., the statics of gases are treated in a similar manner, barometers, air pumps, syphons, and balloons being taken as illustrations. The remainder of the book is devoted to the study of the dynamics of liquids and gases, and is also fully illustrated.

We must confess, however, to a little disappointment as regards the new edition. The writing is at times rather obscure; many things are still retained which, however appropriate in earlier issues, are now archaic; and new matter, which we think it is but reasonable to expect, we have not been able to find.

The paragraphs on recent improvements in the hydraulic press are in parts very far from clear, and the same may be said of those relating to the Torricellian experiment.

Concerning the hydraulic press used by Robert Stephenson to raise the tubes of the Britannia Bridge, we find it stated that "22 tons of fluid incandescent iron were required for this enormous casting. After being left for seventy-two hours in the mould in which it was cast, the mould was detached from it. *It was still red hot!* It was then left to cool, and it was *ten days* before it was sufficiently cool to be approached by operatives well inured to heat." Now, however astonishing such a casting was a quarter of a century ago, yet in view of more recent productions—such as the anvil block of the Woolwich steam hammer, weighing 103 tons—surely the italics and notes of admiration might have been spared.

We are surprised to find our old friend the atmospheric railway still standing its ground. Yet here it is just as in former editions, and without a word of qualification, as if it or a rope were quite usual for working steep inclines. We are told, too, that the use of a locomotive is almost impracticable on an incline of 1 in 50, although such and even steeper inclines are regularly worked by them in several places.

Again, in describing the action of the paddle-wheel and screw in propelling ships, the old engraving representing the most primitive kind of wheel, with fixed paddles, is still shown, and although the waste of power which occurs when the paddle-board is not vertical is demonstrated, nothing is said about the feathering paddles now almost universally employed. The account of the screw is still worse, for we are told that "the screw is usually formed by constructing an helical vane, turning spirally round an axle," and the illustration exhibits accordingly a true "screw," although every one must be aware that the modern propeller is not formed like a screw at all, but consists of two or more blades set round an axis at the same point.

We notice a small inaccuracy in the account of the mercurial barometer, where it is stated that the pressure of the vapour of mercury is "so slight that it could not be measured by the most accurate and delicate means that could be applied;" whereas, according to Regnault, the tension of mercury vapour at 20° C. is ·037 mm.—an amount quite easy to measure.

In the way of omissions, we may mention that nothing is said of Gay Lussac's very convenient form of syphon barometer, and that Andrews' valuable experiments on the behaviour of gases under great pressure are not referred to.

We look in vain, too, for an account of Gifford's injector, or the steam blast, and although the hydraulic press is fully described no mention is made of the application of hydraulic power to lifts and cranes. Hydrometers, with arbitrary scales, by Baumé, Cartier, and Beck, are described, but no explanation is given of the use or supposed advantage of these peculiar scales. Although, as we have before mentioned, the old atmospheric railway is again described, we are disappointed to find that its modern successors, "the pneumatic despatch tubes" and the pneumatic tubes of the postal service for the conveyance of parcels and messages, are not mentioned.

We have given a rather long list of defects, but felt it a duty to indicate some of the points at which improvement might have been made, and a good book made better and more nearly on a level with the present state of scientific and technical knowledge. In spite of these imperfections, we think it is a work which will be very useful as far as it goes, but must express a doubt if it will satisfy the hope expressed in the "advertisement," that it will be a valuable manual, especially for students preparing for the pass examination of the University of London, unless that refers only to the matriculation examination. Apparently this hope is not so restricted, for in the "preface" it is said to be sufficient for those who "desire to acquire that general knowledge of these sciences which is necessary to enable them to graduate;" but we fear that a student who, on these subjects, reads this book alone for the degree examinations would run some little risk of failure.

BOOKS RECEIVED.

Companion to the Latest Edition of the British Pharmacopœia, comparing the Strength of its Preparations with those of the United States and other Foreign Pharmacopœias, etc. By Peter Squire, F.L.S., etc. Tenth Edition. London: J. and A. Churchill. 1874. From the Author.

A Priced Catalogue of Druggist's Sundries, Proprietary Articles, Shop Fittings, Show Cases, and Surgical Instruments, manufactured and sold by Lynch and Co. 1874.

Obituary.

Notice has been received of the death of the following:—

On the 15th October, 1874, Mr. Thomas Blunt, Pharmaceutical Chemist, of the Wyle Cop, Shrewsbury. Mr. Blunt had been a member of the Pharmaceutical Society since 1853.

On the 9th September, 1874, Mr. Francis W. Wheaton, Chemist and Druggist, of Bournemouth.

On the 11th October, 1874, Mr. Thomas Scarby Mason, Chemist and Druggist, of Wolverhampton.

Correspondence.

**** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Pharmaceutical Education.

Sir,—The original object of the Pharmaceutical Society was to raise the status of the pharmacist, and the mode by which it sought to do this was by stimulating education and restricting the exercise of pharmacy to those who could give satisfactory evidence of being pharmaceutically educated. But where there is a prize to be won there are always those who desire to win it without the labour of a race—those who wish to enjoy the higher status without the education upon which alone it ought to depend. The existence of this class is the main source of difficulty to the examiners, and the existence of this spirit in the students is their main source of failure. This disposition, either in teachers or learners, cannot be too much deplored nor too strongly condemned, and must be my justification for presuming to lead your readers again through a path so often trodden.

No one dispassionately considering the subject would require to be told that education is a leading out or developing of power, and that pharmaceutical education should include development of the powers of observing, comparing, classifying, and judging all materials and processes which come under the pharmacist's view, and, above all, it must include the development of his power of *doing* all things required of him in the practice of his art; and no one need be told that such an education cannot take place in the course of a few months devoted to study. It is the duty of the examiners to see that this process of growth has progressed to a satisfactory extent before they pass a student, and the more the teachers and learners persist in simulating a genuine education the more the examiners will, of necessity, develope the examination required to discriminate between a true and a spurious learning. Those who tremble before the growing severity of the ordeal have to thank mainly themselves or their false friends for the position they are in.

A definite curriculum, though much objected to by some, will undoubtedly come in the course of a few years, not as a substitute for examination, but to render it more improbable that any one who has passed through the curriculum and the examination has only that smattering of knowledge against which the public have a right to be protected. An Act of Parliament may compel a student to go to the fountain of knowledge, but ten acts cannot compel him to drink; hence the necessity for following a curriculum with an examination, to sift out and reject such as are too indolent to avail themselves of such opportunities as they are compelled to come within reach of.

But there is another consideration which has been too much overlooked in the discussion of this question, and it is of the more importance, as it affects the better class of students and the public.

In the prospect of an improved *status* we have always included an improved pecuniary position commensurate with the increased education and responsibilities, and this can only be accomplished by diminishing the number of those entering the trade, a restriction which, in a free country, can only result from the legitimate difficulties of attaining the standard which all are free to attempt.

We hear frequent complaints of the difficulty of getting apprentices, and suggestions that youths must be tempted into the trade by cheap education, gratuitous lectures, and help from the funds of the Society to pay the expenses of local institutions which, in many cases, have little claim to be considered educational agencies, but which are supposed to make the youth's path to knowledge easy. All this appears to me to be mistaken policy. We ought rather to rejoice in the paucity of apprentices, as the first step towards the diminution of competition among principals.

Anything of the nature of leniency towards those now in course of study only tends to prolong into another generation the battle against adverse circumstances which now compels the pharmacist to associate patent medicines, perfumery, and pickles with prescriptions, and to distribute his attention among so many branches of business that his pharmaceutical lore becomes rusty with little use, and the public are left only with the services of dispensers who are not well qualified though well examined. By these same adverse circumstances the students who have laboured earnestly and with success are driven into other paths where earnest work meets a better reward.

It may be asked how would I meet the present difficulty, and I would reply, that no one should undertake to teach an apprentice the art and mystery of pharmacy who is not competent to do it, and willing to give time and attention to the task. Those who are not prepared to give instructions for work, they should expect to pay with money for the services of assistants who have got their instruction elsewhere. Nothing can do so much to promote pharmaceutical education as a willingness on the part of employers to pay fairly for the services of competent assistants. Those who take care to pay a small day's wage for a long day's work, and then subscribe handsomely to "the Association," can only be regarded as wearing an outside liberality as a cloak for their selfishness. We cannot expect men to act in a purely disinterested spirit, and pay more than market value for services; therefore, we must look to the care which is quite natural on the part of those who have services to dispose of, the care that they secure for their labour a fair *quid pro quo*, either in the form of money or opportunities for improvement in any part of their calling in which they still require education.

There are times when the cessation of toil is the truest wisdom. When we have done our duty time is on our side, and will do the rest.

Pharmaceutical reformers, having established the machinery which should produce the desired results, have now a period of comparative rest, in which they have to watch its operation and guard it against casualties.

A few hundred rejected students may be regarded as indicative of its working well rather than otherwise, for it is the only evidence which will bring conviction to the minds of those interested that the necessity for education is a reality. The rejection of a few hundred incompetent men would be a blessing to all in the trade, and all competent men about to enter it. It would be a blessing to parents, by convincing them that they had better not bring up to the trade any youths who have not an aptitude for it; and to the rejected men themselves it would be a blessing in disguise. A man had better turn grocer than remain for life an Associate of the Pharmaceutical Society.

Barnard S. Proctor.

11, *Grey Street, Newcastle, October* 22, 1874.

Preliminary Examination Question.

Sir,—I remark the following amongst the questions for the Preliminary Examination published in your last number:—"State the plural of (*inter alia*) *die*." This is not the first time that I have seen the same question, which has therefore somewhat the appearance of a "catch," and in the interests of fair play I am led to ask the examiners *which* answer they would like to have?

What do they mean by "die," and why does not the question specify what is intended?

The plural of "die," known in mechanics, is "dies," and would always be so written amongst practical mechanicians; the plural of "die," known to gamblers, is "dice." May I ask the examiners whether they require both plurals to be given, or will they be content with either, or, if not with either, which?

In the meantime I confess myself

Puzzled.

October 26, 1874.

Colchicum Autumnale.

Sir,—In the *Pharmaceutical Journal* of this week (October 24), at page 328, there is an editorial note, headed "Poisoning of Cattle," and at page 325 there is a statement by J. Pierre, on the toxic action of the *flowers* of *Colchicum autumnale*.

Now this medicinal plant abounds in some parts of the grazing land about this place (North Somerset); the flowers appear in August and September; the leaves and the seed appear in April.

I have never heard of cattle being injured by the *flowers*; grass is abundant in summer, and the cattle pass by the flowers; but in spring, when hungry cattle are turned into a field where the *leaves* of the colchicum abound, and the grass is insufficient, they eat voraciously and indiscriminately, and, in some cases, it is well known they have been poisoned by the leaves of the colchicum, and, I am informed on the authority of an honest cattle dealer, on opening the dead cow, the colchicum leaves have been found rammed hard together, so as altogether to stop the passage.

The farmers try to destroy the colchicum; the most effectual plan appears to be to plough the land.

I do not pretend to be a scientific botanist, but I can affirm the truth of the above statement.

JOSEPH LEAY.

Downside, Chilcompton, Bath, October 24, 1874.

ADULTERATION.

Sir,—We are promised additional legislation on this subject in the ensuing session of Parliament, and it having been sufficiently discussed from legal points of view, I propose to regard it from one of reason and equity.

The evidence educed by the parliamentary committee having shown that comparatively little adulteration is practised, and that scarcely anything of a deleterious nature is used, the tables of mortality further demonstrating that the public health was never better than of late years, and, as it may be safely inferred, competition insures that as good articles as are paid for are usually sold, I submit that no valid reason existed for the imposition of such a measure.

I am no advocate for adulteration, and believe those who are willing to pay legitimate prices for good articles find no difficulty in procuring them; but every tradesman knows there are numbers of bargain-hunting persons, ever aiming at something beyond their station, who are not content with good articles at fair prices, and those who humour their tastes obtain such custom; hence arise silk and woollen goods, cheapened by admixture with cotton, cotton lowered by jute, good wrought-iron displaced by inferior cast, moulded glass made to represent that which is cut, and shop windows glittering with tinsel ornaments for the poor, plated nickel for the middle class, and gilded silver for the rich. And is the press, the legal profession, or even the clerical, exempt from the same practice of substituting the apparent for the real? And the gentlemen known as "*promoters*"—do not they annually extract millions from a confiding public, under representations and calculations the most baseless and fallacious?

Seeing, then, that what is called *adulteration* is often a trade arrangement under which the tastes and wishes of the buyer are satisfied, the question arises. Why should the seller of an ounce of mustard, or cheap coffee, be compelled to state that the former is coloured by so many grains of turmeric, or the latter mixed with a certain portion of chicory, any more than the seller of a fifty-guinea piano should be compelled to explain that the rosewood in its composition is represented by a thin slip of external veneer? And as the public speaker, or writer, may indulge in any amount of specious argument or misrepresentation, so that he does not, by traitorous language, endanger the peace, or, by becoming personal, inflict individual injury, why should not the commercial law be assimilated to the literary, and the public prosecutor only called in when something positively deleterious is substituted for the wholesome, leaving those who think they are imposed upon to the remedy of ceasing to deal with the impostor, or instituting proceedings for the redress of the individual wrong?

I therefore suggest that when the subject is again discussed in Parliament, it be provided that a clause shall be proposed, enacting that prosecutions are only to be instituted at the public expense when any admixture is found which would be *injurious to the health* of those using it, and that in all places returning members to Parliament the tradesmen affected by such legislation should combine and seek an interview with their representatives, to discuss the subject with them, and point out the oppressive character of the present enactment, requesting them to support such amelioration as it may be determined to propose, and they may then hope to secure for the subject a more reasonable consideration than it has at present received.

A COUNTRY CHEMIST.

R. B. H.—When citric acid is treated with strong sulphuric acid a disengagement of carbonic oxide ensues, even without the application of heat. But if the temperature be sufficiently raised, the odour of acetone is perceived, and carbonic anhydride is given off.

M. J. Bentley.—The water always will separate from your mixture if stirred after it has "set." The manipulation should be *secundum artem*—more easily performed than described.

"*Hampton.*"—(1) Formula will be given next week. (2) According to Dr. Weber (*Brit. Med. Journ.*, Feb. 14, 1874), Apollinaris Water contains in 10,000 parts, 25·5 of solid matter, consisting principally of carbonate of soda (12·57), chloride of sodium (4·66), sulphate of soda (3·0), and carbonate of magnesia (4·42). It is also said to be richer in free carbonic acid than almost any other spring.

"*A Student.*"—(1) The sulphur is used in combination with the oil for the extinction of the mercury. (2) Because in that state the properties for which it is used are most fully developed.

Quæstio.—Your letter has been handed to the Secretary.

A. C. G.—You will find ample information upon the subject in our advertising pages.

S. Wylde.—A portion of the iron becomes oxidized, and the iodine liberated colours the solution. A coil of iron wire passing through the whole depth of the liquor will prevent liberation of the iodine; and filtration into the syrup, when dispensed, will separate any oxide of iron that may have been formed. It is not possible to make a syrup which will be the same as the B.P. syrup in the manner you mention, because syrup of iodide of iron contains less water than simple syrup does.

"*An Apprentice.*"—In the other lines the quantity is the direct object of the transitive verb; in the line quoted "aquam" is the direct object.

"*Alpha.*"—The formula for phosphorus pills recommended by Dr. Radcliffe was as follows:—

Phosphorus	6 grains.
Suet	600 ,,

Melt the suet in a stoppered bottle capable of holding twice the quantity indicated; put in the phosphorus, and, when liquid, agitate the mixture until it becomes solid. Roll into 3 grain pills and cover with gelatine. Each pill will contain $\frac{1}{33}$ grain of phosphorus.

G. P.—Wanklyn's "Water Analysis," published by Messrs. Trubner.

G. W. Hamilton.—It would not be difficult for a person possessing the qualifications described by you to obtain an "assistantship with a good chemist."

J. Stevens.—There is no recognized formula for such a preparation.

J. M. J.—You will find a formula for Pepsine Wine in the number for February 28 last, p. 195.

A Young Pharmacist.—We do not think the question instanced by you would be at all out of place in an examination intended to test chemical knowledge, and under certain circumstances it would have a direct pharmaceutical bearing.

R. R.—Mr. Erasmus Wilson's formula for hair wash was published in vol. iv., p. 179.

V. Hughes.—Probably the failure results from unskilful manipulation.

W. W.—The silicates of potash and soda may be readily purchased in a tolerable state of purity, and there is no great difficulty in preparing them pure on a small scale.

"*Cautious.*"—We think a dispenser would be quite justified in declining to dispense such a prescription.

T. G. Hives.—See a paper by Mr. Wanklyn on the relative value of disenfectants, in vol. iv., p. 205.

F. Balkwill.—The ink may be discharged from thick paper by gently rubbing it with a sponge moistened with dilute nitro-hydrochloric acid.

J. B. Shilcock.—If you will point out what part of the subject has not been dealt with in our remarks upon your letter, we shall be glad to consider it further. Though we regret that our comments upon your letter are not satisfactory to yourself, they will suffice to show that we did not consider the publication of your letter would serve any useful purpose.

"*Extortion.*"—We think the case you refer to in your letter is one that you would do well to take legal advice upon before giving publicity to the facts mentioned.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Jackson, Mr. Pocklington, Mr. Bevan, Mr. D. Williams, "A Correspondent," "At Fault."

THE CHEMICAL NOMENCLATURE PROPER TO AN INTERNATIONAL PHARMACOPŒIA.*

BY THOMAS GREENISH, F.C.S.

An International Pharmacopœia has for several years been an idea floating before the eyes of the pharmacists of every European nation. It had been little more than an idea until the Congress in St. Petersburg, grappling with the difficulty, aimed at reducing its requirements to some tangible form. How far success has attended those efforts will be left for time to determine. There certainly was not wanting at that Congress either the energy or the will, but the difficulties were great. Some points on which a definite opinion was pronounced may be mentioned.

The Latin language is to be restored to its former position, and will, I believe, be very generally welcomed as an old familiar friend. The Russian pharmacist may not understand English directions, and the English pharmacist will most certainly not understand the Russian, but both should be conversant with the Latin.

The metrical system of weights and measures will be introduced, and the greatest simplicity is recommended in galenical preparations. The minimum of the active principle in narcotic and drastic drugs permitted will be stated; also the maximum of impurity allowed where absolute purity is not thought necessary.

The very general agreement and unanimity on these points indicate progress,—one step at least in the right direction; but there is still a question on which the Congress did not pronounce a definite opinion. I refer to nomenclature, the object in view being to secure a uniform and fixed nomenclature, the one best adapted for an International Pharmacopœia.

The decision was left to the Permanent International Pharmacopœia Committee, whose seat is in St. Petersburg, a few of the delegates requesting that the system of Berzelius should receive consideration.

Since the return of the delegates to England they have received a letter from that Committee, requesting that each Pharmaceutical Society should state what nomenclature it considered best adapted for an International Pharmacopœia.

Thinking it probable that the favourable opinion of the Berzelian nomenclature expressed at the Congress by a few might be very generally entertained, I was induced to write to the President on this point, and also with the view of eliciting what really was meant by the system of Berzelius, and at the same time requesting a few examples, applicable to the chemicals of the Pharmacopœia. In reply, he states that a few delegates only suggested the nomenclature of Berzelius, and that in his opinion it was not the best nomenclature for a pharmacopœia. He says further, that if adopted for a pharmacopœia, "acetate of lead" would be written "acetas plumbi," "muriate of quinine" "murias quiniæ," and "muriate of morphia" "murias morphiæ," which he considers would be very objectionable. He adds that the nomenclature of the Austrian Pharmacopœia was formerly that of Berzelius, but it is now altered, not from a theoretical but from a practical necessity. Several mistakes had occurred in dispensing; the last case of poisoning was due to an assistant having dispensed from a bottle labelled "murias morphiæ," which he had mistaken for "murias quiniæ." He thinks that had the one been labelled "morphiæ murias," and the other "quiniæ murias," the probability is the error would not have occurred.

I may add that I have received a letter on this subject from a high authority, Professor Dragendorff, of the Dorpat University, Russia, one of the delegates at the recent Congress. He also objects to any system of such names as Carbonas kalicus, in which the metal or basis occupies a secondary place, and agrees, he says, in principle with the names such as Potassii carbonas, the employment of which Professor Attfield urged in his Paper on Nomenclature, read before this Society in 1871.

It must, I think, be admitted as desirable that the nomenclature should not conduce to errors in dispensing, that the system adopted should be generally acceptable, that it should be as uniform and permanent as possible, and yet that the Pharmacopœia should be abreast of the science of the day. The question, therefore, before the meeting is what chemical nomenclature it considers the best to be adopted in an International Pharmacopœia? and to this question the pharmacists of Great Britain, in common with those of other countries, are requested to furnish an answer.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 4, 1874.

THE CHEMICAL NOMENCLATURE OF AN INTERNATIONAL PHARMACOPŒIA.*

BY PROFESSOR ATTFIELD.

The question put to English pharmacists by the Permanent International Pharmacopœia Committee, now sitting at St. Petersburg, lies within narrow limits, We are not asked to discuss the subject of an International Pharmacopœia, nor its whole nomenclature, but simply the (Latin) chemical nomenclature appropriate to such a work.

Before answering this question some deliberation is necessary. Our own British interests must not alone be considered. The chemical nomenclature of an International Pharmacopœia, printed in the Latin language, should harmonize as much as possible with the Latin nomenclature of every national pharmacopœia, of which it is more or less the international representative, and when translated into the respective vernacular languages, should clash as slightly as possible with the chemical names commonly met with in those languages.

On one point, at the very outset, I have a definite and strong opinion. The nomenclature under discussion should reflect modern unitary ideas, and not the old binary or dualistic hypotheses respecting the constitution of chemical substances. Nitre must not be termed potash nitrate, or nitrate of potash, or nitrate of oxide of potassium (KO,NO_5—old atomic weights; or K_2O,N_2O_5—new atomic weights), but potassium nitrate, or nitrate of potassium (KNO_6, old atomic weights; or KNO_3, new atomic weights). Blue vitriol must not be regarded as copper oxide sulphate, or sulphate of oxide of copper (CuO,SO_3, $5\,HO$), but as copper sulphate, or sulphate of copper ($CuSO_4,5\,H_2O$). For the modern unitary views are not only held by nearly all chemists in all countries, and taught in all English and nearly all foreign educational chemical works, but are recognized officially either in the names, synonyms, or notation of most pharmacopœias, and at most pharmaceutical and medical examining boards. In the Austrian

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 4, 1874.

Pharmacopœia appears Magnesium sulphuricum, while Magnesia sulphurica and Sulphas magnesiæ occur only as synonyms. In the German Pharmacopœia we find Ammonium carbonicum, not Carbonas ammoniæ. In the French Pharmacopœia the Sel d'Epsom is still termed Sulfate de magnésie, but Sulfas magnesicus is given as a synonym. In the British Pharmacopœia modern chemistry is recognized by the insertion of modern chemical formulæ, side by side with the old, and that in the next edition a very simple and effectual modification of modern chemical nomenclature should be introduced, is admitted with singular unanimity by the leading chemical, medical, and pharmaceutical authorities of Great Britain, and all the English journals of medicine and pharmacy. It will be for the International Committee to ascertain the nomenclature of pharmacopœias generally, and to collect opinions respecting projected alterations in the chemical nomenclature of such pharmacopœias, but I may just add a quotation from the preface of the recently issued United States Pharmacopœia: "Some alteration has been made in the chemical nomenclature of the pharmacopœia in order to place the work in accord with the progress of chemical science. Without adopting the new nomenclature of chemistry to its full extent, such modification of the former designation of substances has been introduced as to give uniformity; all the salts of the alkaline metals are designated as of the particular metal, and not of its oxide; thus, Barii carbonas is substituted for Barytæ carbonas, Calcii carbonas præcipitata for Calcis carbonas præcipitata, Potassii citras for Potassæ citras, etc. These changes have been made with deference to the nomenclature which is now being employed by chemists, and the modifications thus made will probably soon be the language of pharmacy." I repeat that, in my opinion, some form or forms of modern chemical nomenclature should alone occupy the leading place in an International Pharmacopœia. In such a work of reference synonyms, new and old, may freely be placed under the leading name of a salt, but the names at the heads of the sections should be consistent with the well and widely accepted modern unitary chemical ideas. If this course be carried out, the proposed Pharmacopœia will promote harmony, if not identity, in the chemical nomenclature of pharmacy throughout the world.

Assuming, then, that the claim for modern chemical nomenclature in the International Pharmacopœia is admitted, the second point for consideration is, which modern arrangement or order of Latin words should be employed in the system of names. Shall we have Sulphas cupri, Sulfas cupricus, Cupri sulphas, or Cuprum sulphuricum. Each of these names already occurs in one or other of the more recent pharmacopœias, and each is in accordance with modern chemical views. Shall we have Nitras potassicus, Nitras potassii, Nitras kalicus, Nitras kalii, Potassium nitricum, Kalium nitricum, Kalii nitras, or Potassii nitras. Each of these, or an equivalent, is to be found in recent pharmacopœias, and each is a modern name. The President of the International Congress, lately held at St. Petersburg, draws attention to the Austrian Pharmacopœia, and prefers such a name as Morphinum hydro-chloricum rather than the synonym Chlorhydras morphicus, also given in that pharmacopœia, because, as a matter of practical necessity in the avoidance of mistakes, he would have the more important word placed first in the name, the leading word being more likely than the terminal word to be correctly caught by the eye of a dispenser. I agree with Mr. von Waldheim in the opinion that the name of the basylous constituent of the salt should come first in the name, not because of its medicinal or toxicological importance, for occasionally the acidulous element, or group of elements, is the more powerful, as in Sodii arsenias, but because in the nomenclature of the majority of pharmacopœias, old or recent, the name of the basylous element is so placed, and because uniformity of plan in such a matter is extremely desirable.

Excluding, therefore, names in which the acidulous constituent is placed first, as Sulphas cupri, Sulfas cupricus, Nitras potassicus, etc., there remains the question, which of the two or three varieties of modern chemical nomenclature, in which the metal or basylous constituent has the leading place, is best worthy of selection for employment in an International Pharmacopœia. Shall the authors of that work employ the term Cupri sulphas with English-speaking nations, or adopt the German form of the name, Cuprum sulphuricum? Shall we have Potassii nitras, or Kalium nitricum? Would the French like to see their Protoiodure de mercure and Deutoiodure de mercure termed Hydrargyri iodidum viride, and Hydrargyri iodidum rubrum respectively, or Hydrargyrum subiodatum and Hydrargyrum iodatum rubrum; their own Latin synonyms being Ioduretum hydrargyrosum and Ioduretum hydrargyricum?

One or other of the two varieties of modern chemical nomenclature of which the names just given are illustrations will probably be selected for use in the International Pharmacopœia. Before deciding which is the better, a glance over the following more extended lists may be useful.

LATIN CHEMICAL NAMES EMPLOYED IN THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA.	LATIN CHEMICAL NAMES EMPLOYED IN THE GERMAN OR AUSTRIAN PHARMACOPŒIAS.
Ammonii carbonas	Ammonium carbonicum.
Ammonii chloridum	Ammonium chloratum.
Argenti nitras	Argentum nitricum.
Atropiæ sulphas	Atropinum sulphuricum.
Bismuthi subnitras	Bismuthum subnitricum.
Calcii carbonas	Calcium carbonicum.
Calcii chloridum	Calcium chloratum.
Calcii phosphas	Calcium phosphoricum.
Cupri sulphas	Cuprum sulphuricum.
Ferri lactas	Ferrum lacticum
Ferri phosphas	Ferrum phosphoricum.
Ferri sulphas	Ferrum sulphuricum.
Hydrargyri chloridum corrosivum	Hydrargyrum bichloratum corrosivum.
Hydrargyri chloridum mite	Hydrargyrum chloratum mite.
Hydrargyri oxidum flavum	Hydrargyrum oxydatum flavum.
Hydrargyrum ammoniatum	Hydrargyrum bichloratum ammoniatum.
Magnesii carbonas	Magnesium carbonicum hydro-oxydatum.
Magnesii sulphas	Magnesium sulphuricum.
Manganesii oxidum nigrum	Manganum hyperoxydatum.
Morphiæ acetas	Morphinum aceticum.
Plumbi acetas	Plumbum aceticum.
Potassii acetas	Kalium aceticum.
Potassii bicarbonas	Kalium bicarbonicum.
Potassii bitartras	Kalium hydrotartaricum.
Potassii carbonas	Kalium carbonicum.

Potassii et sodii tartras	Kalium natrio-tartaricum.
Potassii nitras	Kalium nitricum.
Potassii iodidum	Kalium iodatum.
Quiniæ sulphas	Chinium sulphuricum.
Sodii chloridum	Natrum chloratum.
Sodii sulphas	Natrum sulphuricum.
Strychnia	Strychnium.
Zinci sulphas	Zincum sulphuricum.

Either of these two systems of names is in accord with the existing state of chemical science; each is already employed by great nations. Which should be adopted in an International Pharmacopœia?

The names found in the United States Pharmacopœia will doubtless be introduced into the next British Pharmacopœia. All authorities, as I have said, are agreed on this point; and English-speaking pharmacists therefore would prefer these Latin names—those of column 1. The French also would probably prefer them, as more consistent with the genius of their own language. On the other hand, German-speaking pharmacists would prefer such names as those now employed in the Austrian Pharmacopœia—those given in the second column of the foregoing table. Would either of the two classes of pharmacists just mentioned be likely to give up the use of one of the two sets of names in favour of the other. I think not. Irrespective of the merits of either variety, and the advantages of international uniformity of pharmaceutical nomenclature, I am convinced that the general bodies of medical practitioners and pharmacists could not be brought to accept any general alteration in a whole nomenclature. This subsidiary question need not be discussed; it is a case of *non possumus*.

Here we may leave the matter in the hands of the International Pharmacopœia Committee. In the general body of the work one or other of these two varieties of modern chemical nomenclature will, in my opinion, have to be employed. Perhaps, however, in the headings of sections both varieties might be represented. Thus, Ammonii chloridum *vel* Ammonium chloratum. This would be the leading name, printed in uniform capitals; then would follow synonyms (of which there should be the fullest number), then characters, tests, and any processes that may be introduced, and so on to other matters of the section. Finally, I trust that the work will have a copious alphabetical index, containing all synonyms as well as chief names.

[*The discussion on this and the previous paper is printed at p. 372.*]

SUGGESTIVE NOTES ON THE PHARMACY OF AMORPHOUS PHOSPHORUS.*

BY ARTHUR WM. POSTANS.

Before treating of amorphous phosphorus I will make a few introductory and other remarks on the pharmacy of ordinary phosphorus.

For some time past a demand has been springing up for preparations of phosphorus, and the frequent reference to the subject has shown clearly enough, in the words of one of the medical journals, that convenient forms for the administration of this powerful therapeutic agent are amongst the desiderata of modern pharmacy.

We have now many, and some of them elegant, forms for its administration—French and English—and it is still a question whether the compilers of the Appendix to the British Pharmacopœia selected the most thoroughly useful formula for the official phosphorus pill mass. The combination of a resinous balsam like tolu, with yellow wax to form pills, is objectionable on account of their questionable solubility in the stomach. The Pharmacopœia orders—

Phosphorus	2 grains.
Balsam of Tolu	120 „
Yellow Wax	60 „

Put the phosphorus and balsam of tolu into a wedgewood mortar, about half full of hot water, and when the phosphorus has melted and the balsam has become sufficiently soft, rub them together beneath the surface of the water until no particles of phosphorus are visible; add now the wax, and as it softens mix it thoroughly with the other ingredients. Allow the mass to cool without being exposed to the air, and keep it in a bottle immersed in cold water. It may be softened with a few drops of rectified spirit when made into pills.

Might not a dispenser conclude from this hint about rectified spirit, that, in order that the balsam of tolu and wax may be dissolved in the stomach, so as to set free the phosphorus, it is advisable that the patient should take a few drops of spirit, probably in the shape of a good dose of hot brandy and water before each pill?

This pill mass was under discussion at an evening meeting in May last, and I now revert to the subject because I cannot concur in the result of that discussion, which seemed to be in favour of the official formula. I quite agree that the process is practical, so far as it goes, but it does not go far enough. Pharmacy justly takes cognizance of the influence of the gastric fluid on medicines. It is necessary for us to consider not only the nature of the drug or element to be dealt with, and the best mode for dispensing it, but whether or not, when introduced into the stomach, it will as speedily as possible be set free, so as to accomplish the object of the prescriber. This last condition is not satisfactorily fulfilled in the phosphorus pill mass of the appendix.

Probably there is no method which can be so universally adopted for the preparation of phosphorus pills as that by which it is dissolved, with the aid of a gentle heat, in prepared suet, the operation being conducted in a closed vessel.

The pills may then be rolled out, coated with gelatine, and preserved in bottles. It is scarcely necessary to remark that, according to this process, there is no doubt whatever of their solubility in the stomach, and the rapid liberation of the agent enclosed.

With these remarks on the pharmacy of ordinary phosphorus, I will pass on to some suggestions respecting the red or amorphous phosphorus.

As is well known, amorphous phosphorus was discovered by Schrötter, and is prepared by exposing, for fifty hours, common phosphorus to a temperature of from 460° to 480°, in an atmosphere which is unable to act chemically upon it. At this temperature it becomes red and opaque, and insoluble in bisulphide of carbon. Free phosphorus is soluble, while allotropic phosphorus is quite insoluble in bisulphide of carbon. I can confirm by experiments the statements that red phosphorus powder is insoluble in ether, alcohol, or proof spirit, chloroform, olive and cod liver oils: it does not become luminous in the dark until its temperature is raised to about

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 4, 1874.

390°, and it has very slight tendency to combine with the oxygen of the air. When heated to 500° it is re-converted into ordinary phosphorus.

Amorphous phosphorus, I find, is readily manipulated pharmaceutically. I am desirous to draw the attention of therapeutists to this form of the element, and to suggest for their consideration the question, whether phosphorus in this very convenient condition for manipulation would have any value in medicine.

Possibly some pharmacist has already met with this substance in a prescription. If so I should be glad to know his experience regarding it. I myself have altogether failed to find an appropriate solvent, so as to present it in a liquid condition, and can therefore form no opinion as to the chemical or physical action of such a solution. Possibly solution might reconvert it, for from hot oil of turpentine, in which it is slightly soluble, the element is deposited as ordinary phosphorus.

By way of experiment I mixed together the following:—

Amorphous Phosphorus	. . . . .	6 grains.
Liquorice Powder Extract of Taraxacum	of each . .	3 ,,

And found the result to be pharmaceutically a good pill mass, which was rolled into 6 pills; specimens of them were silvered, saccharated, coated with tolu, and put into ordinary pill boxes. At the expiration of a week or so they were found to be as well-preserved as when first made; moreover, I found amorphous phosphorus could readily be mixed with electuaries or confections.

Of course in no case must chlorate of potash be mixed with it, for, if it should, an explosion may result; but, this excepted, it seems to be compatible with almost all powders.

Possibly, in the event of medical men prescribing it, there would be no objection to the use of the powder itself, mixed with an equal quantity of sugar, and taken in jam, jelly, or treacle.

A useful preparation could be introduced by mixing it with black currant paste, to form a lozenge, "of any strength desired."

So much for the pharmacy of amorphous phosphorus. A few days ago I mentioned the subject to my former teacher, Professor Attfield, who very kindly went into the matter with me, and seemed disposed to the opinion that something might be done with amorphous phosphorus, and suggested the advisability of getting some medical men to take up the subject scientifically, bearing in mind the following facts, namely, that amorphous phosphorus can be manipulated easily by the pharmacist, is readily compounded as pills, electuaries, or confections, and that, having diminished chemical energy, there probably would not be the same difficulty, delicacy, or necessity for giving it in such fractional doses as those in which ordinary phosphorus is administered.

We are told that in some cases the ordinary phosphorus in moderate doses acts rather violently, and sometimes the symptoms of poisoning show themselves. Pereira says, after its absorption phosphorus acts as a stimulant to the nervous, vascular, and secreting organs; it excites the mental faculties, and raises the temperature of the skin, increases the frequency of the pulse, and promotes the secretions. He goes on to say allotropic phosphorus is changed into the ordinary kind by friction, so that it answers the purpose of the match maker quite as well as the other variety, while it does not emit vapours when exposed to air. It was formerly described as an oxide, but is now shown to be nothing else than phosphorus in the masked or allotropic form.

In the manufacture of lucifer matches with the ordinary kind the workmen are occasionally liable to necrosis of the jaw bone, whereas, in the case of amorphous phosphorus, it is said to be non-poisonous, and that in the manufacture of these matches it answers precisely the same purpose as the other phosphorus, and the workmen do not find any injurious results from being constantly at work with it.

Touching this point, however, I think it would be interesting to know from some large manufacturer of the patent safety match his experience in the preparation, and some of the details connected with its use, and how far the received statement is correct—that *no* injurious results arise from its manipulation by the men, women, and children employed in such factories, and if anything remarkable or unusual is experienced by those who are constantly at work in its atmosphere, with the symptoms, if any, and the remedy employed.

If in the manufacture of lucifer matches it is found to be perfectly harmless, and yet to answer in every respect precisely the same end as the ordinary phosphorus, surely we may imagine that therapeutically it might to some extent be adopted when the more active one could not so well be given. Here, however, pharmacy touches therapeutics. I simply introduce the suggestion, and in so doing would express a hope that some medical gentleman will take up the matter therapeutically. In the event, too, of any pharmacist having already experimented with amorphous phosphorus, or had his attention drawn to it by prescriptions in which possibly it may have been ordered, perhaps he would kindly communicate his experience to an evening meeting. In short, we desire to know whether this intermediate form of phosphorus has any right or title to be used in medicine for the treatment and cure of disease.

Since writing the foregoing my attention has been drawn to the fact that Dr. Bednar, of Vienna, recently reported very active symptoms as the results of prolonged administration of amorphous phosphorus in small doses. This fact supports me in the opinion that an investigation of the subject would be attended by useful results.

[*The discussion on this paper is printed at p.* 373.]

JABORANDI.

BY WILLIAM MARTINDALE, F.C.S.

Two notices of this new drug have appeared in the *Pharmaceutical Journal** within the last few months. They refer to an article which was brought to Paris from Pernambuco, by Dr. S. Coutinho, who states that this "Jaborandi, the name under which the Indians designate the new substance, is" (the produce of) "a shrub which grows in the interior of some provinces of the North of Brazil, the leaves of which somewhat resemble those of the bay-tree."

Its properties as a diaphoretic and sialagogue are remarkable. The mode of employing it, Dr. Coutinho states, "is very simple; it is only necessary to bruise the leaves and small branches, and make an infusion of four to six grams in a cup of hot water.

* *Pharmaceutical Journal*, 1874, pp. 850 and 911.

Ten minutes after the administration of this infusion—it is not necessary to drink hot fluids—the patient, who should take the precaution to go to bed and be well wrapped, is quickly covered with perspiration, which does not cease to be produced for four or five hours, and which is such that the linen ought to be changed often during that space of time. During this time also there will be an abundant salivary secretion and a bronchial excretion not less abundant, to such an extent that it will be painful for the patient to speak, and his mouth will quickly be filled with liquid. This excretion, in quantity, may equal a litre and more."

A drug producing such physiological effects might be of great service in combatting many diseases, and having with difficulty procured two small consignments from Paris, a little of which I present to this Society, I witnessed a trial of it by Dr. Ringer, at University College Hospital, on two boys under his care. Professor O'Leary, of Cork, was also present. Half a drachm, infused in a little boiling water for ten minutes, was given to each, the whole was swallowed without straining. As stated by Dr. Coutinho, in ten minutes the perspiration became visible on the face of one of the boys, and the whole body soon became enveloped in it; this continued for more than an hour while I waited. The sialagogue effect in this case was not so marked, although the secretion of saliva was above normal. In the other case the salivation was most marked, but the diaphoretic action not perceptible, the boy's face became covered with a suffused flush, the secretion of saliva was very profuse, he had a disinclination to speak, and appeared much depressed. The temperature in both cases fell quite one degree, although at first it was raised a little, and the pulsation also was quickened while the action of the medicine lasted; notes were taken of these, but they are not in our province. Eventually sickness was produced in both cases, but this was after I had left. As the doses were small, half a drachm for boys of about eleven years of age, the trial was sufficient to prove that the drug has a powerful physiological action. Dr. Ringer will, I expect, ere long publish more on this head.

It has been stated in French journals* that there are several kinds of Jaborandi known in Brazil. I am satisfied that the sample I have obtained is the same as that which Dr. Coutinho and Professor Gubler experimented with at the Beaujon Hospital, as M. Adam, the pharmacien at that hospital, informed my correspondent where a little of it could be purchased, so that for authenticating further supplies that may arrive my sample will be of service. The whole leaf is said to be large and impari-pinnate; a translation of Professor Gubler's description of it has appeared in the *Pharmaceutical Journal*. Unfortunately, my sample is broken up into much the same condition in which we receive henbane leaves in commerce, and portions of the petiole are mixed with it. The lamina, which is about the thickness of Alexandrian senna, is much reticulated; the veinlets are raised, and show very distinctly on both sides of the leaf; the margin is entire, and a little re-curved, probably the effect of drying. Judging from a piece picked out measuring three-quarters of an inch across, and which was a complete half section of a portion of the leaf from the mid-rib to the margin, I should think the entire leaf or leaflet is about two inches broad by about four inches long; but this, of course, is doubtful. The lamina contains a number of glands, which are arranged very regularly about half a line apart. These give a peculiar pellucid, dotted appearance to the leaf when looked through towards the light, similar to that in buchu and other rutaceous and hypericaceous leaves. The odour is very characteristic, resembling that of a mixture of Indian hemp, matico, and cubebs. So much is the odour of the last two present, as to lead one to suppose that it must be nearly allied to them, yet it has little pungency in taste. According to Professor Gubler,* Professor Baillon, by comparing Dr. Coutinho's samples of Jaborandi with the Brazilian plants in his Herbarium has been able to assure himself of the identity of Jaborandi with a species of the N. O. Rutaceæ, the *Pilocarpus pinnatifolius*, Lem. But I think this is an error, although the description of the whole leaf given by Professor Gubler exactly agrees with that of some fresh leaves of *Pilocarpus pinnatifolius* obtained by Mr. Holmes from Kew Gardens. The margin of the leaflets of the latter becomes a little recurved on drying, but the veinlets appear much more raised on the under surface of the leaf than on the upper. The dotted glands are about the same size, perhaps a little more numerous than those on the Jaborandi. But the odour and taste of the leaf of *Pilocarpus pinnatifolius*, when dried and bruised, is very distinct from that of Jaborandi; its odour resembles that of the ivy leaf bruised, and the infusion in boiling water smells somewhat like that of boiled spinach. The taste is peculiar, rather pungent, and produces a tingling sensation upon the tongue. The administration to a boy, 12 years of age, of half a drachm of it infused in boiling water, in about 20 minutes produced merely a little flushing in the face, the diaphoretic and sialagogue action were entirely absent. Of course these leaves were from a plant of hot-house growth; grown in its natural habitat its effects might be different; but still, Dr. Ringer and others, as well as myself, who watched the cases, and examined the leaves and infusions of both, were satisfied this was not the same as the Jaborandi we had tried before.

I have mentioned that the somewhat aromatic odour of Jaborandi would lead one to suppose that it was the produce of one of the Piperaceæ, but botanists think differently. Professor Oliver, at Kew (as well as Professor Baillon), thought it was a rutaceous leaf. Yet there is a species of pepper undoubtedly called Jaborandi, the *Piper Jaborandi*, Velloso, the reticulations of which, by reference to specimens in the British Museum Herbarium, I find are much like those of this obtained from Paris; but the dots are arranged mostly in parallel rows on each side of the smaller veins, and are more numerous and smaller than on the other, the leaf also is more papyraceous, and I think larger, than the leaf or leaflet of Jaborandi. Its leaf also is simple, not pinnate, as the whole leaf of Jaborandi has been described by Professor Gubler. By comparison with the leaves of other species of *Piper* at the British Museum and Kew, by the kind permission of Mr. Carruthers and Professor Oliver, I was not able to make out any that resembled my sample. If it be a pinnate leaf, it was, perhaps, a waste of time to look in that Natural Order for it.

The *Monniera trifolia*, Aublet, N.O. Rutaceæ, goes by the name of Jaborandi in some parts of Brazil,† but the leaflets of this are small, not larger than that

* *L'Union Pharmaceutique*, 1874, p. 123.

† *L'Union Pharmaceutique*, 1874, p. 186.

of the common privet, which it somewhat resembles. Among the rutaceous plants which Mr. Holmes and I examined at Kew, *Ticorea jasminiflora* and *Galipea heterophylla* most resembled the sections of leaf I picked out of the Jaborandi. Until we get a further supply, which is expected ere long, including the organs of reproduction, we shall, I think, be unable to say what the name of the plant is that yields the drug under our notice. From what I have lately learnt this kind of Jaborandi is well known in Pernambuco.

As regards the chemistry of the drug, Dr. A. Rabuteau has examined it, but with no very definite results. He finds* that it contains—(1) a volatile principle, inert; (2) a part soluble in water, and devoid of taste, also inert; and (3) a part insoluble in water, but soluble in alcohol, and possessing a bitter taste. On this last he found, by experiment upon himself, depends its sialagogue and other effects. He did not find any alkaloid or definite active principle present in it.

NOTE ON JAPANESE OIL OF PEPPERMINT.

BY JOHN MOSS, F.C.S.,

Late Demonstrator in the Laboratory of the Pharmaceutical Society.

At the last evening meeting of the Society, the opening meeting of the session, there was placed on the table a specimen of so-called crystallized oil of peppermint, this having been presented to the museum by Messrs. Cyriax and Farries. The specimen excited considerable interest, and did not seem to have been previously met with by those who examined it. I therefore thought it might be useful to ascertain what was known of the body, and, if it presented any points of interest, to place these before the Society. I may premise that the particular sample in question is part of a parcel which was received from Japan, in a cylindrical tin canister, along with a bottle of the liquid oil, a specimen of which is presented to the museum by Messrs. Corbyn & Co.

It appears that in 1862 a memoir on crystallized oil of peppermint, from Japan, was presented to the Chemical Society by Oppenheim.† This chemist speaks of the substance coming to this country in considerable quantity in earthenware jars, and of its being adulterated with sulphate of magnesium—to which it has a close resemblance in crystalline form—to the extent of 10 to 20 per cent. This is far from being the case now, for the result of many inquiries is to find that the body is almost unknown here (indeed, Mr. Hanbury is the only gentleman to whom I have applied who is at all acquainted with it);‡ and, so far from being adulterated with sulphate of magnesium, the specimen on the table, if not absolutely pure, is at least free from all impurities not derived from the original oil.

Oppenheim called the subject of his experiments, *camphor or stearopten of peppermint oil*, and also *menthol*. In Dr. Attfield's 'Manual,' peppermint camphor is styled, more systematically, I think, hydrous menthene, *menthene* ($C_{10}H_{18}$) being the hydrocarbon which is known to be common to several, if not all, varieties of peppermint oil. Oppenheim found that his camphor fused at 36° C., and boiled at 210° C.; that it was very slightly soluble in water, very soluble in alcohol, ether, bisulphide of carbon, fatty and essential oils, and in alcoholic solutions of the caustic alkalies—from the soda solution it crystallized in long needles. It was insoluble in aqueous alkalies. It liquefied in a current of hydrochloric acid or of sulphurous acid gas, resuming the solid crystalline character unchanged on exposure. From solution in strong acids it was separated by water as an oil, which soon solidified with properties unchanged. Having repeated these experiments, I have no hesitation in saying that the present specimen, if not the identical body examined by Oppenheim, is a physical isomer of it; for I find that it fuses at 39° C., re-solidifies at 37·5° C., and boils at 215° C. It should be stated, however, that the boiling point remained stationary for some seconds at 210° C., so that there is the probability of this specimen being a mixture of Oppenheim's camphor, with a more condensed body having higher fusing and boiling points. There may be a number of such isomers, for Dumas,* by exposing at 0° C. American oil of peppermint, which resembles the Japan oil in furnishing crystals at a relatively high temperature, obtained crystals which, when purified, fused at 25° C., and boiled at 208° C. In other characters they resemble the crystals from Japan oil. By exposing the liquid Japan oil to cold for some days (a great part of the time below 0° C.) I failed to obtain crystals. It is therefore probable that this oil has already yielded such as it is readily capable of doing. This is indeed what one might expect, for it is not easy to see the object of sending both crystals and liquid into the market, if the original product does not spontaneously deposit the former, and so give an inconvenient mixture of solid and liquid. Both Oppenheim and Dumas concur in ascribing the formula $C_{10}H_{20}O$ to the bodies they examined. Time, or the want of it, has not permitted me to verify this. The menthol from spearmint described by Gladstone† has the formula $C_{10}H_{14}O$. It boils at 225° C. Oppenheim considers, on very good grounds, that the body from Japan oil is a monatomic alcohol, $\left.\begin{matrix}C_{10}H_{19}\\H\end{matrix}\right\}O$ *menthylic alcohol*, or *hydrate of menthyl*.

In an experiment with liquid Japan oil it commenced boiling at 206° C, the temperature rose to 210° C, where it was stationary for some time, and finally reached to 218° C. This, therefore, is a mixture of two or more bodies; but as menthene, according to Oppenheim, boils at 163° C, this hydrocarbon does not enter into the mixture.

Crystallized *Chinese Oil of Peppermint* is mentioned in the work 'Pharmacographia'‡ recently issued by Mr. Hanbury in conjunction with Dr. Flückiger. It is there referred with reserve to *M. arvensis*. Oppenheim distinctly gives *M. piperita* as the source of the camphor he examined, and he does not hint at a Chinese origin. It is stated in 'Pharmacographia,'§ that to distil *M. arvensis* with *M. piperita* ruins the flavour of the oil yielded by the latter plant. I consider this strong positive evidence that *M. arvensis* is not the source of Japan oil, for this oil is not greatly inferior to the best Mitcham oil in point of fragrance. If a demand for it were to arise in this country (by confectioners, etc.), there is little doubt that it could be supplied at a low price

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 7, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed " Pharm. Journ."*

RECRUITING FOR MEDICAL DISPENSERS.

"A competent and steady dispenser can obtain a salary of £30 per annum, besides board and lodging." "The work is by no means arduous, and those engaged in it would always be well fed and sheltered." Attention "youths of both sexes" in Great Britain, who may be suffering from competition in overcrowded callings! This new land, flowing with milk and honey, is within your view, and the modern JOSHUA who will portion out your lot in it is an M.D., who makes the announcement through the medium of the *Daily Telegraph.* Brought into competition with such a benefactor, Sergeant KITE and his colleagues ought soon to have to take off their recruiting ribbons and wait for harder times, leaving the War Secretary to bless the great invention of "skeleton" regiments; whilst the "Song of the Shirt" should surely at once become but a relic of a state of things which has passed away!

But who has created this glorious prospect? Can we answer the question without being thought egotistical? Nay! So let the "M.D." answer it for us; and he says the Pharmaceutical Society! It is to the action of the Pharmaceutical Society the fact is due that "medical practitioners are greatly in want of assistants competent to dispense medicines and keep books," for—says M.D.—their difficulty "has been considerably increased since the Pharmaceutical Society has set up examinations of a high standard." Lest therefore, in these days of Conservative reaction, even the myriad-tongued *Daily Telegraph* should not make itself heard by all, we gladly help in proclaiming that food and shelter in a medical dispensary, and £30 a year, are to be had for little more than the asking.

But will recruits flock to the standard? "I can call spirits from the vasty deep," boasted GLENDOWER. "Why, so can I," retorted HOTSPUR, "or so can any man; but will they come when you do call for them?" An analogous question arises here. Judging by the aid of experience communicated from all parts of the country, we are inclined to believe that even "M.D.'s" dazzling promises will not attract many "youths of both sexes," and, speaking frankly, we hope they will not. For it will not do to lose sight of the fact that many pharmacists offer in vain better—we will not say more liberal—terms to qualified assistants; whilst their desire to give a remuneration still more in keeping with the skill and education which conscientious pharmacists now expect their assistants to possess, is curbed by the fact that they too often have to compete with the "open shop" of a medical practitioner, served by an "assistant competent to dispense medicines and keep books," but without any pharmaceutical qualification. Therefore, if unable to give much encouragement, we will venture a little advice to medical practitioners suffering from the "assistant" famine, and that is, to abandon as far as possible the work of dispensing medicines and selling drugs, proprietary preparations and the like, to those whose legitimate vocation it is.

Of course the old retort will be made with respect to chemists and druggists prescribing over the counter, and we confess we wish it had not so much force. But if one thing more than another has tended to perpetuate this unhealthy practice, it has been the custom which has obtained so widely with medical practitioners in respect to their assistants. Unfortunately the Pharmaceutical Society's "examinations of a high standard" are not yet compulsory upon the assistants, either of medical practitioners or of pharmacists. There has been, therefore, and there still is, nothing to prevent the drafting of a "youth" from an "overcrowded calling" into the dispensary. Of course, when there, he would not be allowed to dispense medicines until he is "competent," but whilst acquiring the moderate amount of pharmaceutical experience that has hitherto given the right to commence business as a chemist and druggist, he has also become accustomed to the practice of prescribing for small ailments in his employer's absence. Is it strange, then, that the taste, once acquired, should be persistent, when it is found helpful also in filling the till? The taste is one, however, which the Pharmaceutical Society has never assisted to develop.

Should sufficient interest be excited by the manifesto of "M.D.," to induce him to send another communication to the *Daily Telegraph*, we suggest that he should take the opportunity of stating how long an interval would be required generally between the drafting of a "youth of either sex" from an "overcrowded calling" into the dispensary, and the time when the youth is deemed sufficiently "competent" to receive the munificent stipend of a gentleman's servant.

THE SCHEELE MEMORIAL.

WE are sorry to note, from the report of the discussion at the meeting of the Council last Wednesday, that the invitation issued by the pharmacists of Sweden to the pharmacists of other countries, and officially communicated to the Council of the Pharmaceutical Society, to assist in defraying the expense of erecting a monument to SCHEELE in his native town, has hitherto practically received no response in Great Britain. Some of our readers will thank us for informing them that subscriptions may be paid to MR. ELIAS BREMRIDGE, 17, Bloomsbury Square.

TIPPLING IN BITTERS.

THE instinctive deference to the principles identified with Good Templarism that manifests itself in the various disguises under which alcohol is imbibed is probably as widely diffused as is the love for fermented liquors. With SAIREY GAMP it took the form of a teapot; with some of her patronesses—if we may believe the Saturday Reviewer—it probably cropped up as toilet necessaries. In the United States this modern PROTEUS appears to have assumed the garb of "bitters," and it is stated by the *Boston Journal of Chemistry* that "thousands of persons, who would never touch ardent spirit in its ordinary forms, take these disguised drams habitually." It appears that Mr. HENRY VAUGHAN, the State Assayer of Rhode Island, has lately made an analysis of thirty varieties of these "bitters," including all the favourite "brands" in the market. He reports that he found the amount of alcohol in them to vary from 6·36 to 59·14 per cent. Twenty-three out of the whole number contained more than 30 per cent., while only six fell below 20 per cent.

COD-LIVER OIL.

IN a recent letter describing the fisheries about Newfoundland, it is estimated that the total catch of cod along the coast is not less than 1,650,000 quintals, and the quantity of oil extracted from their livers one and a quarter million gallons, valued at about £200,000. Nearly all of this oil, it is added, is shipped to England, the duty in the United States being so high at present as to almost prohibit its importation, otherwise much more of it, if not all, would go to that market.

TOOTH-ACHE PENCILS.

IN reply to a letter forwarded by us to the Board of Inland Revenue respecting the doubt which exists as to the necessity of affixing a stamp to tooth-ache pencils, we have been informed by the Secretary to the Board that "Harvey's Tooth-ache Pencil is not liable to a stamp."

PHARMACIES IN PARIS.

THE *Lancet* states that, according to the Census recently published by the Prefecture of the Seine, there are in the city of Paris 618 pharmaceutical establishments, and 298 in the suburbs.

WE have been informed that at the last meeting of the Directorate of the Austrian Pharmaceutical Society, Mr. THOMAS GREENISH was elected an Honorary Member, and Mr. FRANCIS SUTTON a Corresponding Member, of that Society.

THE Chair of Chemistry in the University of Dublin is now vacant, through the resignation of Dr. APJOHN.

Transactions of the Pharmaceutical Society.

GENERAL MEETING—BENEVOLENT FUND.

A general meeting of the Members and Associates in Business of the Pharmaceutical Society, and of the Subscribers and Donors to the Benevolent Fund, was held at the house of the Society, 17, Bloomsbury Square, on Friday, October 30th, for the Election of FOUR ANNUITANTS.

Mr. T. H. HILLS, President, in the chair.

The notice convening the meeting was read.

Scrutineers were appointed, and having examined the voting papers, brought up the following

REPORT.

We, the undersigned scrutineers, appointed at the tenth election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following result:—

	Votes Polled at		TOTAL.
	Election, 1873.	Election, 1874.	
1. Atherton, William	....	374	374
2. Beaton, Elizabeth	895	944	1,839
3. Bellingham, Henry James	....	2,820	2,820
4. Linging, Bine	129	154	283
5. Markland, Edwin	....	893	893
6. Moss, Mary	1,351	1,147	2,498
7. Phillips, Dorothy	....	481	481
8. Wick, Sophia	....	1,318	1,318

Nine voting papers were informal, and were disallowed.

ALEX. BOTTLE, *Chairman.*
THOMAS GREENISH.
J. ROBBINS.
WALTER DUTCHMAN.
HENRY HILLIER.
GEORGE W. SANDFORD.
ROBERT HAMPSON.

October 30, 1874.

The Chairman declared the following duly elected:—

ELIZABETH BEATON.
HENRY JAMES BELLINGHAM.
MARY MOSS.
SOPHIA WICK.

MEETING OF THE COUNCIL.

Wednesday, November 4th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Frazer, Greenish, Hampson, Mackay, Owen, Radley, Rimmington, Robbins, Sandford, Savage, Schacht, Stoddart, Sutton, and Williams.

The minutes of the previous meeting were read and confirmed.

THE NORTH BRITISH BRANCH.

Mr. MACKAY said that, having received from the Secretary a copy of the report of the deputation which recently visited Edinburgh, he had called together the members of the North British Board of Examiners, and read it to them. They were very pleased to find that the arrangements in Edinburgh met with the approval of the deputation, and determined to carry out the few suggestions on matters of detail contained in the report. He might also mention that great satisfaction was felt at that part of the report which suggested that in future there should be, at least once a year, a visit by some members of the London Board to Edinburgh, and a reciprocal visit by some members of the Edinburgh Board to London. So much good feeling had arisen from the interchange of opinions by members of the two Boards, that it was believed this practice would tend to produce good results which could not be attained in any other way. Mr. Mackay also stated the formal arrangements which would be necessary for granting a lease of the new premises in Edinburgh to the Society.

The Scheele Memorial.

The President inquired how many subscriptions had been received towards the Scheele memorial.

The Secretary said he had not yet received any.

Mr. Williams announced, as a commencement, a subscription of one guinea each from Messrs. J. Bell and Co., Mr. Hills, and himself, and said he should be happy to receive any further names.

Mr. Greenish suggested that the subscription list should be left in the office, as he objected, on principle, to such matters being brought before the Council formally.

Mr. Williams said the subscription list should be placed in the office, and he hoped to find a considerable number of names added to it.

The Congress at St Petersburg.

Mr. Greenish said he had received the *Austrian Pharmaceutical Journal*, containing the President's report of the recent Congress. Mr. v. Waldheim's report to the Austrian Pharmaceutical Society, of which he is the Vice-President, was practically identical with the one which had been already submitted to the Council by himself and Mr. Sutton. Mr. v. Waldheim also expressed very warmly indeed his pleasure at the sympathy and support he had received, as President of the Congress, from the English delegates, especially as, their institutions being so different, they had no direct interest in some questions before the meeting. The Pharmaceutical Society of Austria had paid the Society of Great Britain the compliment of naming one of the English delegates an honorary, and the other a corresponding, member of that Society. His object in rising, however, was principally to supply an omission which had been made on the former occasion, and, as had been done by the Austrian Society, to move a vote of thanks to the St Petersburg Society and its President. He would therefore move—

> "That the Council of the Pharmaceutical Society of Great Britain desire to convey to his Excellency Privy Councillor von Trapp, to the Pharmaceutical Society of St Petersburg, and to the Organization Committee their best thanks for the cordial reception experienced by the delegates of this Society at the International Pharmaceutical Congress at St Petersburg."

He thought such a resolution would be an act of international courtesy, and was quite sure it would be as highly esteemed as it was richly deserved.

Mr. Schacht, in the absence of Mr. Sutton, had much pleasure in cordially seconding the motion, which was carried unanimously.

Elections.

APPRENTICES OR STUDENTS.

Francis, Rawson Parke...............Diss.
Savory, Arthur Ledsam ....London.

Two members who had neglected to pay their subscriptions in proper time were ordered to be restored to their former status, on payment of the current year's subscription and a fine.

Finance.

The report of this Committee was read and adopted, and sundry accounts ordered to be paid.

Benevolent Fund.

This Committee reported that it had held two meetings since the last Meeting of the Council, and recommended that the following grants be made :—

Ten pounds to a registered chemist and druggist, now out of employment, but formerly in business for seven years in Suffolk.

Fifteen pounds to a registered chemist and druggist, aged 68, formerly in business in the Minories.

Ten pounds to the widow of a late annuitant at Liverpool, being the second grant this year.

The consideration of another case was adjourned, in order that the Committee might see the applicant personally.

The Regulations had been discussed by the Committee, but the further consideration thereof was adjourned to the next meeting.

Letters of thanks were read from some of the successful candidates at the recent election, one of which contained a suggestion that the limit of age should not be rigidly insisted on in special cases of affliction, such as blindness, paralysis, or other disablement. The letter was referred to the Benevolent Fund Committee.

The Report and recommendations were received and adopted.

Library, Museum, and Laboratory.

The Report of this Committee contained a recommendation for the purchase of the following books for the library :—

'Southall's Organic Materia Medica.'
'Garrod's Materia Medica.'
'Index to Journal of Chemical Society.'

The Librarian had reported that the average attendance in the library from July 8th to August 1st was, in the day 16, at night 6 ; and from the 1st to the 13th of October, daily 13, at night 5. The number of books issued between July 8th and October 13th had been, in London 248, to the country 113, the number of places being 49. He had also presented the following list of 16 books which are missing from the library :—

'Barber's Companion to the British and London Pharmacopœias,' 6th edition, 1872.

'Bloxam's Laboratory Teaching,' 1869.

'British Pharmacopœia,' 1867.
'Clendon's Observations on the Extraction of Teeth,' 1843.
'Cooke's Botanic Terms,' 1862.
'Dyer's Intensity Coils: How made and how used,' 2nd edition, 1867.
'Hogg on Skin Diseases,' 1873.
'Jones's Natural History of Animals,' vol. 1, 1852.
'New York College of Pharmacy Alumni Association, Third Annual Report.'
'Orme's Introduction to the Science of Heat,' 1871.
'Parlatore's Coniferas Nonas Nonnullas,' 1863.
'Pereira's Selecta è Præscriptis,' 11th and 12th editions.
Piesse's Art of Perfumery,' 1862.
'Thorpe and Muir's Qualitative Chemical Analysis,' 1874.
'Timbs's Knowledge for the People,' parts 5, 7, and 10. 1871.

Professor Attfield had reported that in the Practical Chemistry Class, up to the 14th October, there had been forty entries since the commencement of the session, and that forty students were now at work.

The Curator of the Museum had prepared a code of rules, which he suggested should be sanctioned by the Council for the guidance of students using the museum, and of which the Committee approved. One of the proposed rules was to the effect that conversation should not be allowed in the museum.

The VICE-PRESIDENT said if they withdrew from the students the privilege of meeting in the museum, it was a question whether there was any other room in the building which they could give them for the purpose, because he conceived it was a great advantage to students to be able to meet and talk over matters in which they were interested. He himself did not see much objection to a conversation taking place in the museum.

Mr. GREENISH said the objection on the part of the Curator was to young men going in and lounging about, sitting on the table, with walking-sticks under their arms, and gossiping about all kinds of matters not at all connected with their studies. The Committee most heartily approved of the whole of the rules.

Mr. SAVAGE thought the rules were very good, but he agreed with the Vice-President, that some room should be appropriated to the use of the students for conversation.

Mr. WILLIAMS thought the musuem was the most convenient room available, as conversation there seemed less objectionable than anywhere else.

The PRESIDENT thought they had better leave the matter as it was at present. If the students required a room to meet in for any particular purpose, no doubt it would be found for them on application.

Mr. ROBBINS said he apprehended the Curator would not prevent students speaking to one another in an ordinary way, but he only wanted power to put a check to too much sauntering about and gossiping.

The Report was received and adopted.

HOUSE.

This Committee presented a report with reference to certain details connected with the gas-lighting of the library, museum, etc.

LAW AND PARLIAMENTARY.

This Committee reported the result of certain legal proceedings taken by the solicitor against offenders under the Pharmacy Act, the details of which have already appeared in the Journal.

The SECRETARY stated that one of the parties referred to, who had obtained leave to appeal to a superior court, had that morning paid the fine and costs, so that it was probable no further proceedings would be taken.

After some further conversation, the Report was received and adopted.

REPORT OF EXAMINERS.

October, 1874.

	Candidates.		
	Examined.	Passed.	Failed.
Major, England and Wales	2	0	2
Minor, " "	7	2	5

ELECTION OF EXAMINERS.

The PRESIDENT reminded the Council that at the next meeting they would have to elect the Board of Examiners for the ensuing year.

Mr. WILLIAMS said he thought it was desirable that the Council should know some time beforehand who were the candidates, in order that they might have an opportunity of considering whether it would be advisable to make a change or not. He therefore suggested that any member of the Council should mention the name of any pharmaceutical chemist he would like to have appointed. He would also suggest that they should only elect twelve instead of fourteen. There had recently been a great pressure on the examiners, but they had reason to believe that that was now over, and that for the next year, at any rate, there would not be so many candidates. He therefore thought it would be as well only to appoint twelve examiners, though, of course, they could at any future time elect two more if it were necessary.

Mr. GREENISH said this was a most important question, and one on which he had already more than once expressed his opinion. He felt it was exceedingly difficult to get good Examiners either in London or in the country, and if gentlemen residing in the country were chosen, a considerable expense was involved. He intended to propose that each member of the Board should be ballotted for separately, because it would be exceedingly invidious to leave out any member who had been on the Board for many years, and to appoint another in his place, but at the same time he thought it most important that there should be an occasional change, and he saw no other mode of accomplishing it. It was astonishing how soon examiners got into a groove, until at last young men coming up to be examined could pretty well ascertain the character of the questions which would be asked. He also thought there should not be any gentleman on the Board who was not practically engaged in that on which he professed to examine. He considered it was their bounden duty to have the Examining Board in the highest state of efficiency possible, without any reference to individual feeling.

Mr. SAVAGE thought it would be desirable for the Secretary to communicate with gentlemen proposed to be elected or re-elected, in order to ascertain whether they wished to retire or would serve if elected.

Mr. HAMPSON thought this was a very excellent suggestion, and also approved of the plan proposed by Mr. Greenish.

The VICE-PRESIDENT said the Board of Examiners would look upon it as utterly impracticable to reduce the number from 14 to 12. At the last examination there was a discussion whether the Board, as now constituted, would be able to get through the work in a day, and whether there would not be a difficulty to complete the Minor examination in one day, on account of the addition of practical chemistry to the subjects. It would, therefore, be premature to contemplate reducing the number of examiners at present, and imposing on the twelve gentlemen who were left more arduous duties than they now had. He agreed that it was the duty of the Council to select the best men the Society could procure as the Board of Examiners, but when it was proposed to elect them by ballot, he would refer to the 10th section of the bye-laws, which said that the Council should "appoint" the Board of Examiners. He took it that "appointing" was not "balloting." The Council ought to look about and see where they could themselves find the best men for the position, and not look upon them as candidates who were to be elected like annuitants on the Benevolent Fund. He should not at all scruple, if he believed that any member of the Board, from any cause, was not a fit man, to do his duty openly by appointing a younger and better man in his place, and he did not want the protection of the ballot in so doing. He maintained that they had no power to elect from a list of candidates.

Mr. Savage said there was a general bye-law which allowed a ballot to be taken on any question, if it were demanded.

Mr. Greenish remarked that when, some twelve months ago, he made a somewhat similar suggestion as to the desirability of changing the members of the Board of Examiners, no notice was taken of it; but several of the examiners had spoken to him upon the subject privately, and every one of them considered that it would be an advantage if such a plan were carried out.

Mr. Schacht said, although they all agreed that it was desirable to have an occasional change, because no doubt a man might ultimately drop into a kind of groove, there was no doubt that the duty of examining involved qualities which were learned by experience, and therefore he did not think a man would be so efficient an examiner the first year as he would be the third or fourth. He had understood from some very able examiners that they really considered the duty of examining well as one of the most arduous duties of their lives; in fact, it was quite a problem to themselves to sound the capacities of candidates. It was, therefore, clearly not a quality that an ordinarily clever or capable man must necessarily possess, and therefore he did not think any plan should be adopted which would tend to change the Board very much, but rather one by which they could gradually superimpose a good element upon rather an inefficient one. His notion upon the matter was that the word "choice" was the correct one, and he did not think it could best be performed by going through the process individually. If there were a list of fifteen or sixteen names, out of which fourteen were to be chosen, each member of the Council would no doubt conscientiously do his utmost to select the best names.

The President wished to bear his testimony to the excellence of the Board of Examiners, having had the honour of presiding at several examinations since he had been President of the Society. He thought they had a most excellent set of examiners, at the same time he was quite ready to do all he could to obtain better, if possible. But they must be careful, before getting rid of those who had served them so well, that they had as good men to fill their places. He did not think it possible at present to reduce the number of examiners, if the duties were to be performed satisfactorily.

Mr. Sutton said if they had good men on the Board they had better keep them; if not, they must try and replace them, but they must be careful not to make any change which would not be for the better.

Mr. Betty said the question raised by th Vice-President was, whether they could elect examiners by ballot? He should like to have it decided.

Mr. Sandford, having referred to the bye-laws upon this point, said he understood Mr. Williams's wish was that any member of the Council who desired to bring forward the name of a gentleman to act as examiner should give notice before the time of election, that it might be ascertained beforehand whether he would serve if elected. He did not consider "candidate" was the right term to apply. The Council could only "appoint" a certain number, and if any fresh examiners were appointed, some of the old ones must be omitted; upon a vote being taken a ballot had in such cases been usually adopted as a matter of delicacy.

Mr. Williams said his only object in mentioning the matter was, that if the names were not mentioned until the next Council meeting, there would be no time to consider them. In his opinion, they could not direct too much care, time, and attention to the appointment of the Board of Examiners, or to any mode which could be suggested for the better carrying out of the arrangements. He was quite sure that this examination question was the one great question which the Society would have more seriously to consider than any other, and if any improvements could be made in the present Board it was their duty to adopt them.

Mr. Hampson said it was almost impossible to agree on the best men unless they had time to consider their qualifications. He understood there was a resolution passed at the last Council meeting referring to this point.

The Secretary said the question was raised, but no resolution was passed.

Mr. Frazer said he wanted each member of the Council to exercise his individual judgment with regard to each examiner, and he could not see any mode by which this could be done, except by nominating them individually. If fifteen names were proposed, he would rather vote for them individually than in a mass.

Mr. Greenish remarked that Mr. Williams had said that they should get the best men; but there might be two men equally good, and he considered it most important that the Board should be gradually changed. It was not altogether a question whether A. was better than B., for they might be equal; but if A. had been on the Board for a certain length of time, he considered it would be a better test of the efficiency of the students that another examiner should take his place.

Mr. Williams thought it was the intention of the Act that there should be occasional changes in the Board.

Mr. Robbins thought the question would be very easily decided; for instance, if any gentlemen liked to propose two other names, there would be sixteen, and each member would then have simply to strike two out of the list in order to leave fourteen, who would be elected. If there were anyone whom it was considered desirable to remove, it could easily be done in that way.

After some further conversation, it was moved by Mr. Sandford, seconded by Mr. Williams, and unanimously resolved:—

"That as the Board of Examiners for the ensuing year must be appointed at the next meeting of Council, it is desirable that any member of Council desirous of introducing any pharmaceutical chemist as an Examiner, should send the name of such person to the Secretary before the 23rd inst."

Mr. Sandford said this would give the Secretary an opportunity of ascertaining from the person nominated whether he was willing to serve, and the name could then be put on the agenda for the next Council meeting.

It was also resolved:—

"That the Secretary be instructed to communicate with the present Board of Examiners, and any others who may be suggested as suitable persons for examiners, asking if they are willing to accept office if elected."

The International Pharmaceutical Congress.

Mr. Greenish begged to present to the Council a photograph of the members of the recent Congress at St. Petersburg. In connection with this subject, it would be in the recollection of the members that a resolution was passed at the last meeting, that the International Congress be invited to hold its next meeting in London. He had written to ascertain to whom this invitation should be sent, and was informed that the invitation to the next Congress had always been sent in the form of a letter from the inviting Society to the President of the previous Congress, who would direct it in turn to the Presidents of the Pharmaceutical Societies of different countries. He would, therefore, propose that the resolution be conveyed in that manner to the President of the last Congress, and he should like it to be signed by the President and Vice-President of this Society.

This suggestion was acceded to.

PHARMACEUTICAL MEETING.

Wednesday, November 4th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed, the following donations to the library and museum were announced, and the thanks of the Society were awarded to the donors :—

To the Library :—'Calendar of University College, London, 1874-5,' from the College ; 'Calendar of the Royal College of Surgeons of England, 1874,' from the College ; 'Medico-Chirurgical Transactions,' vol. 59, from the Royal Medical and Chirurgical Society ; 'Pharmacographia,' by Prof. Flückiger and D. Hanbury, F.R.S., from the Authors ; 'Index Plantarum Officinalium in Horto Chelseiano, 1730,' by I. Rand, from Mr. E. M. Holmes ; 'Sur la Recherche des Substances Amères dans la Bière,' by Dr. Dragendorff, from Dr. J. Morel (Translator).

To the Museum:—A specimen of Jaborandi, from Mr. Martindale ; a specimen of Japanese Oil of Peppermint, from Messrs. Corbyn and Co.; a specimen of Crystallized Stearopten of Japanese Oil of Peppermint, from Messrs. Cyriax and Farries ; a number of specimens of the Drugs of Morocco and Brazil, from Dr. Leared ; a specimen of genuine Turkey Rhubarb, from Mr. Greenish.

THE NOMENCLATURE PROPER TO AN INTERNATIONAL PHARMACOPŒIA.

The CHAIRMAN then called upon Mr. Greenish to introduce the discussion upon this subject. This Mr. Greenish did by reading a Paper, which is printed at page 361.

The PRESIDENT said this was a most important question, and well worthy consideration and discussion. He would call upon Professor Attfield to open the debate.

Professor ATTFIELD, before reading his paper, said he must apologize for preceding his seniors on an international question like this—one in which England should clearly have a prominent voice. The simple reason was that, having had the pleasure some three years ago of publishing a paper on chemical nomenclature generally, and on that which would probably be employed in future editions of the British Pharmacopœia—a paper which had been very favourably received by most authorities, chemical and medical, as well as pharmaceutical, in England and elsewhere—he anticipated that something more than a mere opinion would be expected from him. He had therefore written down a few remarks on the general principles which he thought should be followed in discussing the question, and he had endeavoured to bring that question to a distinct issue. As he understood, they had not to entertain the question of publishing an International Pharmacopœia or not, or the general character of such a work, the preparation of which he believed was in the hands of a committee already appointed, so that they really had no voice in those matters.

Mr. SUTTON said that was not so. Every one had a voice in the question of construction.

Professor ATTFIELD was glad to hear this statement from one of the delegates to the recent Congress. He had feared that the general principles of construction had been, or might be, fixed without seeking international opinions. Clearly, however, the question they had to consider that evening related not to the general nature of an International Pharmacopœia, nor to its whole nomenclature, but simply to its chemical nomenclature, or rather to the Latin chemical nomenclature appropriate to an International Pharmacopœia, and to that question he should confine his attention.

Professor ATTFIELD then read a paper "On the Chemical Nomenclature of an International Pharmacopœia,' which is printed at p. 361.

Professor REDWOOD entirely concurred in what had been stated by Professor Attfield, who for several years past had taken a great interest in this subject, and who had certainly contributed greatly towards the establishment of a greater amount of uniformity and consistency among pharmacists and medical men with regard to the chemical nomenclature of medicines than previously existed. Indeed, so far as he could gather, they were indebted to him in great measure for the introduction, on the other side of the Atlantic, in the United States Pharmacopœia, of the system which he had advocated some years ago. He (Dr. Redwood) had previously expressed his opinion as being favourable to such a change as had been suggested by his colleague—in principle, if not in every particular detail—and he did not doubt that whenever a new edition of the Pharmacopœia came out, a similar nomenclature to that now adopted in America would be adopted. It must be borne in mind, however, that in the adoption of any new system of nomenclature as applied to pharmacy, they were limited to a considerable extent by what was practicable ; the nomenclature of the Pharmacopœia was to be used by medical men, and to be understood by pharmacists ; names were but representatives of things, and when persons had once thoroughly learned the language, and become acquainted with the things which certain names represented, it was not an easy matter, especially in mature life, to change the language they had been in the habit of employing. Now, the medical men in most extensive practice were not young men ; but, generally speaking, men who had acquired their scientific knowledge some half century ago, and who were not prepared to go to school again. In recommendation of the proposal made some years ago by Dr. Attfield, and now again brought forward, it may be said that while it would reconcile the nomenclature of the Pharmacopœia with modern views in chemistry, it would at the same time make the system of names more specific, clear, and consistent with itself, and, which was a still greater recommendation, it would involve a very small amount of change, one which would be inappreciable as used by medical men, for the abbreviated names as recommended would not differ from those now in use. The difference was in the termination, and the termination generally, of the basylous constituent of a salt. He had indeed found, in discussing the matter with medical men, that very little difficulty would be found in adopting it. As the English language was spoken over so large a portion of the globe, he hoped and thought they might have reason to expect that the nomenclature adopted in the proposed International Pharmacopœia might be one which, while applicable to the Latin language, would be strictly applicable to English also, and would necessitate very little change on the part of English physicians and pharmacists. He was very glad that the subject had been introduced by one of the members of the recent Congress at St. Petersburg, and hoped the opinion of the members would go forth almost unanimously upon it.

Mr. GROVES said it appeared to him that if any change were made in the nomenclature of the Pharmacopœia, it ought to be a final one ; and with that object they ought, if possible, to avoid any approach to adopting a particular chemical theory. Chemical theories were changing from day to day; probably before the end of the present generation a very serious alteration indeed would take place, and therefore, if any nomenclature were adopted as expressive of the theory of the day, it would probably soon require another change. From this consideration he was rather inclined to look with favour on the nomenclature adopted in the German Pharmacopœia. Many of the terms certainly sounded barbarous to an English ear; perhaps they might be softened down, but they did not express any theory.

Mr. Ince said he would limit his remarks entirely to the Latin nomenclature of the proposed International Pharmacopœia. He disagreed with the views expressed by the last speaker, for the following reasons:—The proposed Pharmacopœia was to be in Latin, and he believed the time would come when the official Pharmacopœia of every country would again be issued in Latin, though an edition in the vernacular might also be published; consequently, in framing the nomenclature to be employed, the genius of the Latin language should be followed as closely as possible, and no attempt should be made to depart from it. Now, looking at the two lists of names given by Professor Attfield from this point of view, there could not be a shadow of doubt that those which had been adopted in the United States must be followed, whilst those in the other column could not, if the book was to be published with any pretensions to correct Latinity. For instance, the terms Argenti nitras, Calcii carbonas, etc., were precisely what one would expect to find in a work written in Latin, whilst the names contained in the German and Austrian Pharmacopœias were to a considerable extent German and Austrian adaptations. To take the Latin for distilled water: if you followed the English form exactly you would have Destillata aqua, but following the Latin construction it would be Aqua destillata. Looking at the matter simply from this point of view, there was an immense superiority in the names suggested by Professor Attfield, which he hoped therefore to see adopted.

Mr. Martindale desired briefly to call attention to one or two instances of the Berzelian nomenclature; the perchloride of mercury was called Chloretum hydrargyricum, whilst calomel was called Chloretum hydrargyrosum. How was this to be modified to suit prescribers? The same thing occurred with regard to the two chlorides of iron, Chloretum ferricum and Chloretum ferrosum. The question was whether they should adopt a nomenclature with inflexions for such compounds at the termination of the words, or as prefixes. He thought the prefixes were certainly much better adapted to the contractions used in prescriptions, and they were generally used both in England and on the Continent. He quite agreed with what had been said by Professor Attfield as to the nomenclature of Berzelius, which had been used in many continental pharmacopœias. Such names might be given as synonyms, but it would be scarcely possible to adopt them as headings.

Mr. Bland thought this discussion was rather premature, though he appreciated the desire of Mr. Greenish and other gentlemen to be in the first ranks of advanced pharmacy. In fact, he was reminded of the time-honoured direction of Mrs. Glasse with regard to cooking a hare—first catch it. In like manner he would say, first catch your International Pharmacopœia, and then talk about the nomenclature to be adopted. Mr. Greenish said he had had the idea floating before his mind for some time, but he ventured to doubt whether the vision would be realized before the present generation of pharmacists had all gone to that bourne from whence no traveller returned. At any rate, before its realization, there would be plenty of time for new chemical theories to arise, and the present so-called unitary notation, which he could not believe would have a very protracted existence, would doubtless have given place to another. He could also confirm what had been said by Dr. Redwood about the difficulty of inducing medical men to adopt any alteration in the Pharmacopœia; and more than that, there were special types of disease and modes of treatment which seemed indigenous to particular countries, which it would be difficult to transplant to other localities where similar diseases did not prevail.

Mr. Sutton desired to state most unreservedly that the whole question of an International Pharmacopœia was quite open to their discussion, and would so remain for a long time. The Congress had, very wisely in his opinion, arranged that their meetings should only occur at intervals of four or five years, and as to this particular question, Mr. Greenish and himself were simply commissioned to bring it before the Society, in order that all members might express their opinions freely as to the nomenclature which should be adopted. What was agreed to at the Congress was this, that if an International Pharmacopœia were to be formed—for that was not yet settled, and he was not quite certain whether they would be any the better for one—but assuming such a thing should be considered advisable, that it should be as short and accurate as possible, so as to embrace all those things as to which differences of practice might seriously affect the public health. They could not introduce numerous articles which were in common use abroad, but they wanted some universal system of using powerful drugs, so that a prescription would be understood in the same sense all over the world, and that, perhaps, might, in the course of a few years be attained. Foreigners had notions of their own about nomenclature, which were sometimes very different from those current in England; but at any rate, if Latin were used, as Mr. Ince had said, it ought to be as good Latin as possible. To show the prevalent misconceptions about this matter, he might mention that a member of the Congress had stated that the English method was to say Acetas plumbi, whereas he thought they should say Plumbum aceticum, which was more correct because the most important name of the two came first. It was, however, quite new to him (Mr. Sutton) to hear that the English did say Acetas plumbi; and inasmuch as they said Plumbi acetas they were substantially at one with their critic. To show how important it was that they should consider this subject, one very enlightened member of the Congress had remarked that the English were very heterodox, but unfortunately they were so important they could not be shut out. Therefore, if they could arrive at anything like uniformity of opinion, there was no doubt it would be treated with great respect, and very probably adopted.

Mr. Greenish said that one or two of the members of the Congress mentioned the system of Berzelius, and the Permanent Committee at St Petersburg was requested to consider it. When they left that city, it was thought that the determination of this point would be left mainly to that Committee; but since then a letter had been received in which it was particularly mentioned, each society being requested to send an answer as regards the nomenclature. It appeared that the Berzelian nomenclature was mentioned by a delegate from Denmark.

The President, in closing the discussion reminded the members that the Congress had been invited to hold its next meeting in London, before which time he hoped some definite opinion would be arrived at.

The Pharmacy of Amorphous Phosphorus.

Mr. A. W. Postans then read a Paper entitled "Suggestive Notes on the Pharmacy of Amorphous Phosphorus," which is printed at p. 363.

The President said this was a most interesting subject, but they would be in a much better position to discuss it after further therapeutical experiments by the medical profession.

Mr. Mackay remarked that phosphorus was just now a very fashionable remedy, and if this amorphous variety could be used instead of the highly poisonous phosphorus, of which they had known so much, it would be a great boon. He remembered, however, that some time ago a lecturer in the North, when speaking of these very substances, had referred to the amorphous phosphorus as being almost entirely harmless, so much so that he believed as much as an ounce had been given to a dog without producing any bad effect. As far as he knew, it had never been tried therapeutically, and it was therefore much to be desired that experiments should be made. With regard to that terrible disease, necrosis of the jawbone, which used to affect those employed in the manufacture of lucifer matches, he might mention that not long ago he had had an opportunity of going through Messrs. Bryant and May's factory, where he found that not only the red, or amorphous, but the ordinary phosphorus was used in very large quantities, and he therefore inquired whether those engaged in the manipulation were subject to this disease, and if so, whether those who used the amorphous kind enjoyed any immunity. He was surprised to find, however, that, going back for a great many years, there had not been a single case of disease in the manufactory, even in the use of ordinary phosphorus, which was attributed by the manager to the fact that the most complete ventilation was insisted upon at all seasons of the year, so that the men and boys seemed to be really working in the open air instead of in closed chambers, as had formerly been the practice.

Professor ATTFIELD said that amorphous phophorus had been used in medicine some years ago, though not extensively, except by a few practitioners. He was informed by a person engaged in the trade, that though there was a considerable demand for it some ten or twelve years ago, it had lately been seldom required. At that time, however, thereapeutists did not seem to know so much about the peculiar effects of phosphorus as they did now, when it was very generally prescribed, and therefore it occurred to him that with this increased knowledge therapeutists would be in a better position to test the qualities and medicinal properties of amorphous phosphorus. Very contradictory opinions had been expressed as to its physiological effects, and therefore it appeared very important that therapeutists should experiment with this powerful element in this particular form, and give the world the benefit of their experience. All experiments should be with red phosphorus containing no trace of ordinary phosphorus, or resulting observations would be valueless.

Mr. GREENISH said that some time ago a medical man, whose prescriptions he made up, was in the habit of prescribing amorphous phosphorus, but he had since then given it up entirely, and used the ordinary kind. Some time ago there had been an account in the *Pharmaceutical Journal* of a meeting of the Medical Society, at which a preparation, called syrup of phosphorus, was very highly spoken of, and said to contain about one-tenth of a grain of phosphorus in one drachm. It appeared to him that if this answered the name given to it, of an elegant preparation of phosphorus, it would be a desideratum, and he therefore got a small quantity, and asked his son to examine it, which he did very carefully, but out of one or two ounces he was unable to obtain any trace of free phosphorus. Not liking to trust entirely to this investigation, he asked Mr. Plowman to examine some of the same syrup, which he did; but he also was unable to find the smallest indication of the presence of free phosphorus, though it did contain a little hypophosphorus acid. It did, therefore, seem that they were as yet entirely without what might be called an elegant preparation of phosphorus in the fluid form.

Professor REDWOOD said the last remark induced him to say a word on this subject, because he differed entirely from Mr. Greenish. In his opinion, they had a most elegant preparation for the administration of phosphorus in the fluid form. It was one the formula for which he had already published on more than one occasion, being the same he advised about twelve months ago, when the subject came before the Society. It was a form for the convenient administration of the fluid preparation of phosphorus ordered in the Pharmacopœia. In the present Pharmacopœia there were two preparations of phosphorus, the Oleum phosphoratum and the phosphorus pill, and he had never heard any exception taken to the former of these, except that it did not very readily admit of administration in an agreeable and convenient form, and though exception had been taken to the pill, he did not think it was founded on any just ground, and considered both these preparations to be entirely unexceptionable. The solution of phosphorus in oil had been used for many years on the Continent, and when the oil was previously prepared as indicated in the Pharmacopœia it formed an excellent solvent. He had kept phosphorus in solution in oil of almonds for many months, and if not exposed to the light it kept perfectly well. It was luminous in the dark, it smelt strongly of phosphorus, and it had the ordinary disagreeable taste. A few drops formed a dose, and the only question was how it should be administered. The Pharmacopœia did not profess to indicate how medicines should be prescribed, but left that to the physician. He had endeavoured to answer the question, and the method he had indicated would be found in the Journal, and he had also published it elsewhere. He recommended it as an emulsion, and a most perfect, elegant, and agreeable emulsion it formed; a tablespoonful of it could be taken without disgust, it would keep for any reasonable length of time, and it perfectly fulfilled all the requirements of a medicine. It was made by taking a drachm of the phosphorated oil, two drachms of yolk of egg, six drachms of syrup of tolu, a drachm of Liquor potassæ, and sufficient chloroform water to make up to six ounces. There was no doubt a little art in mixing it, because if the yolk of egg and phosphorated oil were mixed together, and the Liquor potassæ put in, it formed a magma, to which the chloroform water and syrup could not be afterwards added with advantage; but if the phosphorated oil, the yolk of egg, the syrup of tolu, and the chloroform water were well rubbed up together, and then the Liquor potassæ added and well shaken up, a good emulsion would be produced which would keep for several months. It had an agreeable taste, the odour was nothing offensive, and no decomposition took place. Of course, if ordinary water were used, the yolk of egg would undergo decomposition and become offensive; but the chloroform water had the remarkable property of preventing such decomposition, and he did not think they yet knew half the extent of its applicability in pharmacy. He had kept an emulsion of this kind for three or four months in a vessel occasionally open, and it was as sweet and good at the end of the time as at the beginning. In fact, he considered chloroform water one of the best vehicles they had for many medicines, and the emulsion thus made with it was an elegant and not disagreeable form for the administration of phosphorus. Something might no doubt be done with the amorphous phosphorus, but they did not know much about it as yet, and therefore he thought it better to keep to the form in which it was known, and in which it might be very easily and effectually administered. The phosphorus pill of the Pharmacopœia had also been referred to, which consisted of a solution of phosphorus in balsam of tolu, hardened with a little wax. This form had been criticized by some gentlemen, simply because they had taken a superficial view of the subject. As with regard to phosphorated oil, they were not to suppose that everything ordered in the Pharmacopœia was just in the form in which it was to be taken. It was left to the physician to prescribe these things, and a hint was given that the pill might be softened with a few drops of spirit. Exception had been taken that it would remain undissolved in the stomach, and pass through the intestines the same as it went in, and he could not question the evidence of the very competent gentleman who had investigated its effects in that way. Still there was great difference in different individuals, and pills were not taken nowadays like the perpetual antimony pill used to be taken generation after generation, never being administered without being searched for again and used repeatedly. It was not intended that this pill should be so used. The form in which it was ordered in the Pharmacopœia was most suitable for its preservation, and it had the great advantage of being in a resin heavier than water, so that it might be readily kept from the air. The specimen on the table had been kept nearly twelve months, and was as good as when first made; but when it had to be administered it could be made easily miscible with the contents of the stomach by adding one grain of soap to three grains of the pill. There was a glass of water on the table in which a pill so prepared had been placed, when it became totally disintegrated and diffused through the water, just as it should do in the stomach. The only thing, therefore, to make this pill perfectly miscible was to add a little soap. It might perhaps be said why was not the soap ordered in the formula given in the Pharmacopœia; but it must be obvious that if it had been the pill-mass could not have been kept excluded from the air by its immersion in water, which was one of the characteristics of this preparation. From the beginning of the process for making the pill-mass to the time at which it was dispensed for administration, the phosphorus and the mass containing it was never exposed to the air, and the phosphorus was thus kept in an unoxidized state. A remark had been made that perhaps a better mode would be to dissolve the phosphorus in suet, and roll the mass out into pills and coat them with gelatine; but he should like to know what would become of the suet pills when put into melted gelatine. If phosphorus were to be administered in solution in tallow or fat (and he was by no means opposed to that mode of administering it, although he preferred the other), he would suggest a means by which the pills could be much more readily formed, and afterwards preserved, namely, by the addition of a little phosphate of lime. He had been accustomed in his lectures to recommend this method of making fatty bodies such as mercurial ointment into pills. If two drachms of mercurial ointment were mixed with one drachm, or a little more, of phosphate of lime, it acquired a perfectly good pilular consistence; and having mentioned this matter in a lecture in that room some twelve months ago, one of his pupils suggested that phosphorus might be dissolved in suet and made into pills in the same way, and a few days afterwards he brought him some so made, which were in every respect perfect. Such pills had also this great advantage, that, being heavier than water, they could be kept immersed in water for any length of time in a state ready for administration.

Mr. Martindale said one objection to the phosphorus pill mass as recommended by Professor Redwood was, that it would require eight grains to be taken for an ordinary dose, and as people did not generally like to take two pills three times a day, he thought it would be much better if the same quantity could be put into one pill.

Professor Redwood said the preparation might easily be made stronger, as the balsam would readily dissolve a larger proportion of phosphorus.

Mr. Martindale said another objection was, there were no means of knowing when the phosphorus was entirely dissolved in the tolu while making it. At the meeting of the Pharmaceutical Conference at Liverpool, he had given a formula—which was, phosphorus 1 per cent., dissolved in cocoa-butter, much in the same manner as the Oleum phosphoratum is directed to be prepared, and, after considerable experience in the administration of this element, he found this the best form in which it could be given. It certainly required a little dexterity in manipulation to roll them out, but this could be easily acquired by a skilful dispenser. He exhibited pills of it containing one-thirtieth of a grain of phosphorus in an unoxidized form; they were varnished, and they dissolved readily at a low melting point, much lower than that of suet. He remembered Mr. Gerrard's formula, but the objection to it was that there was greater chance of oxidation, and the pills could not be well coated.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' ASSOCIATION OF IRELAND.

The winter session of this Association commences on Monday, November 9. It is intended to form classes on chemistry, botany, and materia medica, and the Society is promised the co-operation of Professor Tichborne and Dr. Smith. The funds of the Society are in a very satisfactory condition, and altogether the coming session promises to be one of great success. It is expected that Government will introduce a Pharmacy Bill for Ireland early in the session.

Parliamentary and Law Proceedings.

Four Children Poisoned by "Teething Powders."

Considerable excitement has prevailed in Romford for the past few days, owing to the very painful circumstances under which four young children, ranging from ten months up to just over two years old, have died, after having had administered to them powders obtained from the shop of Mr. J. W. Lasham, pharmaceutical chemist, High Street. The names of the children were Reginald Copsey aged a year and seven months; Sarah Jane Keeble, between ten and eleven months old; Joseph Brazier, aged a year and three months; and Septimus Adams, aged two years and one month. In the case of each of the children the taking of the powders was followed by a stupor, succeeded by convulsions in two of the cases, death supervening in from 12 to 18 hours. Mr. Lasham was from home at the time the powders were procured.

On Thursday, October 29, Mr. H. S. Haynes, Deputy Coroner for the Liberty, opened an inquiry at the County Court. The following particulars were taken from full reports in the *Essex Times*, the *Essex Independent*, and the *Sussex Herald*.

The first case gone into was that of Reginald Copsey, and from the statement of the mother it appeared that on the previous Monday evening, as the child was suffering from its teeth, she sent her little girl to Mr. Lasham's for a teething powder, the deceased having previously received relief from the powders. The powder received was wrapped in pink paper, with directions to give it in jam. This was done, but the child was very sick, and immediately brought it up; a second powder was sent for and put into a feeding bottle with some milk and water, and given to the child, which appeared stupid, and noticed nothing. About two o'clock on Tuesday morning it was restless; but again fell into a stupor, and the mother thought it was asleep; about ten o'clock, however, Mr. Potter, surgeon, was sent for; he thought the child was suffering from croup, and said it would not live, and it died about two o'clock in the day. The child could not take anything, and had not had anything likely to disagree with it.

The second case investigated was that of Sarah Jane Keeble. Mrs. Keeble said the child, which was generally healthy, was on Monday suffering from teething, and she went to Mr. Lasham's for two teething powders (having used them with satisfactory results before), one for deceased and one for her little boy; but as Mr. Urpath, an assistant in the shop, said he did not think it would be strong enough for the boy, who was two years and ten months, she only took one for the deceased, a part only of which she administered in a little of her own milk about half-past nine on Tuesday morning. The deceased was put to bed about ten, and about half-past eleven the mother's attention was called to it by a peculiar noise in the throat. As the deceased did not rouse when she moved it, she let it lie until one o'clock, when she called in Mr. Wright, surgeon, who said he thought the child had croup, and at his direction a warm bath was provided and mustard plasters applied. Mr. Wright said she would not recover, but an hour or two afterwards he said he thought her better. The child, however, never regained consciousness, or moved from the time it was laid down, and died about nine the same evening.

In reply to questions from the jury, Mrs. Keeble said there was no vomiting. From what Mr. Wright said she afterwards asked Mr. Urpath for the prescription of the powders for Mr. Wright, and he said if Mr. Wright would call he would give it to him; the powder given her was one previously prepared.

In the case of the deceased, Joseph Brazier, the mother, Mrs. Ann Brazier, said the child was generally healthy, but as on Monday it was suffering from its teeth she sent to Mr. Lasham's for a teething powder, which she gave to the child about half-past seven, in some tea and sugar. Immediately afterwards the child got down from the chair, sat down before the fire, and seemed to go off in a drowsy state. About eight he was put to bed, but afterwards hearing him make a curious noise, and seeming to be in a fit, she took him to Mr. Davey, surgeon, whose assistant said he was in a convulsive fit, gave her some medicine and two powders, and ordered a warm bath. He managed to get one of the powders down, but it took no effect on the child. Later she managed to give him a little medicine, but with no result, and he did not move all night until nine the next morning, when he moved his eyes; at half-past twelve he moved a little, and died at one. There was no vomiting, but a little froth at the mouth.

In the case of Septimus Adams, Mrs. Adams said the child's health was very good, but on Wednesday, thinking he was suffering from his teeth, she sent to Mr. Lasham's for some teething powders, having had some before which had done the child good. About one o'clock her husband administered the powder in her presence, and about an hour afterwards the child frothed at the mouth; after a time he roused, but went off again about six o'clock. His lips turned black, and he lay in that state until about eleven o'clock.

Mr. Wright was sent for and attended, and was told that the child had had a powder from Mr. Lasham's. Mr. Wright advised a warm bath and mustard plasters, and asked to be informed as to the state of the child at nine o'clock. He was then advised that the child was in the same state, and he stated that he feared there had been some mistake, and that the child had taken morphia in the powder, and he had had other cases. He used the stomach pump, and administered some coffee, but said there was no hope for the child. Mr. Wright came again in the course of an hour, but the child remained in the same state of unconsciousness from six o'clock until it died about four on Thursday morning in strong convulsions. During the afternoon the child had one or two acidulated cough drops, but nothing else.

At this stage the inquiry was adjourned until Saturday afternoon, to allow of *post-mortem* examinations to be made.

On the resumption of the inquiry on Saturday afternoon last, before Mr. Haynes, Mr. W. R. Preston watched the inquiry in the interests of Mr. Lasham and his assistant, Mr. Lawrence, who were also present.

The Coroner, having read the evidence taken on Thursday, said he now proposed to take the medical evidence, when

Mr. Wright stated that he understood that Adams's child had an attack of convulsions before taking the powders.

The father, Mr. Adams, was called, and, in reply to the Coroner, said on Wednesday, about half an hour before he administered the powder, the child had an attack of convulsions, and he had had three or four children who had had the same kind of fits while teething.

The inquiry into the death of Reginald Copsey was then proceeded with, and

Mr. C. Potter, surgeon, said that about half-past eleven on the previous Tuesday he was called to see the child, and found it apparently dying. There was an accumulation of mucus about the throat, and a general lividity of the countenance. Being told that the child had been suffering from cold, he thought it might be suffering from croup or suppressed scarlatina. The pupils of the eyes were contracted, an undoubted sign of poisoning by opium, though he did not think there had been poisoning then, as there was so little life left that he could not say what the sinking proceeded from. On an examination of the stomach he found it empty, except about two teaspoonfuls of the kind of fluid generally found in the stomach; the stomach was healthy; there was slight congestion of both lungs, especially at the back part, in consequence of gravitation, and the right side of the heart full of blood; there was a little effusion of blood on the brain; the congestion of the lungs and the blood on the brain point to the death being caused by opium. The result of the *post-mortem* was doubtful, the appearances deviating so little from the general appearances that no one could say death resulted from opium. No one could say positively from the appearances that there had been any overdose. Examined by Mr. Preston, witness said the symptoms before death were consistent with croup; the appearances of the *post-mortem* were not inconsistent with croup.

Susan Price Copsey proved going to Mr. Lasham's and asking for a teething powder for a baby eighteen months old, and it was supplied to her by Mr. Lasham, sen., and afterwards she went to Mr. Lasham's for another, which was handed to her by Mr. Urpath.

Mr. Urpath, assistant to Mr. Lasham, who was cautioned that he need not answer questions unless he liked, admitted that the previous witness came on Monday evening for a teething powder, and he handed her one from a drawer where they were ordinarily kept. He did not know how long they had been made, nor who mixed them up; the composition of the powders was calomel, Dover's powder, and compound powder tragacanth. Witness here appeared to be in a fainting condition, and his examination was postponed until he had somewhat recovered, when he said there should be one grain of calomel in each five grains of powder, one and a half grains of Dover's powder, and one and a half grains of compound powder tragacanth.

By Mr. Seaward: I have not been in the habit of making the powders up of late, but they were made on the premises.

A Juror: Who makes them?

The Coroner: The witness says he does not know who made these particular powders.

Mr Potter, recalled, said he received a portion of the powder from Inspector Pepper, and handed it to Dr. Medlock for analysis.

Henry Medlock, analytical chemist, said he received a powder from Dr. Potter, with a request to analyze it. The powder was contained in a small paper; there was a trifle under a grain of it. He examined it chemically and microscopically, and found it contained calomel; he could not state the quantity—it was too small. He tested it specially for morphia with two distincts tests, viz., with nitric acid, which gives a brown colour, and with sulphuric acid and chromate of potash, which gives a greenish purple colour. With this second test he obtained a greenish purple colour, but not the brown colour with the first test, which failed to produce that result. The microscopic test was indefinite as far as regards the calomel; there were calomel and organic substances. He made no further test, the quantities were so small; and he could not swear positively that morphia or any constituent of opium was present, but the reaction obtained led him to infer the presence of opium.

Mr. Preston: Supposing there had been three grains of this stuff, would it have been possible to have killed anybody with it?

Witness: I won't say that.

Mr. Preston: Then I understand you won't venture to say that three grains of this stuff you have had handed to you would kill anybody?

Witness: I won't venture to say.

Mr. Preston: If one ingredient in this powder was calomel would another be Dover's powder?

Witness: I cannot say that it was Dover's powder, but I got indications of opium.

Mr. Preston: That would be Dover's powder?

Witness: It might be.

Mr. Preston: Was there any compound of tragacanth?

Witness: It would be impossible to detect it, because there is no chemical test for it.

Mr. Preston: What you found would not be inconsistent with it?

Witness: No, certainly not; but I found what I considered to be morphia.

Mr. Potter, in answer to Mr. Preston, thought that a grain of calomel, one grain of Dover's powder, and one grain of compound tragacanth powder would be an overdose for a child of that age, though he did not think it would prove fatal. There was too much Dover's powder, it containing one-tenth of opium.

In the case of the child Keeble, Mr. A. Wright, surgeon, said when called to it between one and two o'clock on Tuesday, it was supposed to be suffering from croup. It was unconscious, motionless, breathing irregularly, and the pupils were very much contracted, and the skin cold and clammy. From these appearances, he was led to think the child was under the influence of some narcotic poison, and knowing that teething powders contain a certain portion of opium, he was under the impression the child was suffering from an overdose. He made a *post-mortem* examination on Friday; found all the organs free from disease; the lungs congested, right side of the heart full of fluid blood, the vessels of the brain very distended with blood; the stomach contained about a teaspoonful of thickish fluid. He applied the nitric acid test for morphia, but did not find any. He preserved the stomach and remainder of contents of stomach. Judging from the symptoms during life and the negative evidence of the *post-mortem*, he thought death had been caused by an overdose of opium. The death, however, was consistent with convulsions or croup.

Mr. Preston: If a child had been suffering from convulsions or croup, would one of the powders be likely to have some effect on the brain when otherwise it would not have?—Yes; my impression at the time was that the child was in such a state as to make the brain particularly liable to the action of opium.

Do you think one of those powders would hurt a child of that age?—Not under ordinary circumstances.

Mr. Urpath deposed to supplying Mrs. Keeble with a powder from the drawer where they were ordinarily kept. The powders were of different degrees of strength, one class being for children from six to twelve months, and others from twelve to sixteen months; they were kept in the same drawer, but in different boxes. He could not say which class of powder it was he gave to Mrs. Keeble.

In the case of the deceased child Brazier, Mr. Jones, assistant to Mr. Davey, surgeon, was called. Mrs. Brazier brought the child to the surgery on Monday evening, and he found it to be suffering from convulsions. He supplied the mother with two powders and a bottle of medicine. He afterwards heard that the child was dead, and gave a certificate that it died from convulsions, though he did not see it at or after death.

The Coroner cautioned witness not to do so again.

Mr. Wright deposed to the result of the *post-mortem*, and said the internal organs were free from disease, but the lungs and brain were congested. Removed the stomach and part of intestines for analysis if necessary. As to the cause of death, appearances were compatible with opium; three half grains calomel would not produce congestion.

Mr. J. Lasham, sen., said he attended to the business while his son was away. He had no recollection of supplying anyone with teething powders while he was there, but might have done so.

In the case of the deceased child Adams, Mr. Wright said he first saw the child at 7.30 on Wednesday evening, and was told it had had convulsive fits; found it in a convulsive state; looked upon it as beyond hope; went to Lasham's from what the mother said, and returning to Adams's, and hearing it had had a teething powder, applied the stomach pump, but without avail. Next morning took a portion of contents of stomach to Mr. Lasham, who said it evidently contained morphia, and showed witness the test of it. He made a *post-mortem*. The lungs and brain were congested, and the lining membrane of stomach slightly inflamed. From the examination and symptoms preceding death, believed death was caused or accelerated by opium.

By Mr. Preston: Morphia would soon become absorbed in the system.

Mr. Lasham, jun., said he did not know who mixed the powders. Sometimes he did and sometimes the assistants. Could not say who made that particular batch of powders. The description of components of powder given was correct, and he had no reason whatever for supposing that the usual proportions of ingredients were departed from.

Arthur Lawrence, assistant to Mr. Lasham, after being cautioned by the Coroner, said he had been in the habit of making up powders. Description given of ingredients was correct. Could not say who made up that particular batch, nor when or who made up the last lot. Had no recollection of any of the parties calling, but they might have done so.

By Mr. Preston: I made up powders from time to time as required, but none specially.

This being the whole of the evidence the Coroner proceeded to sum up, and after reviewing the facts in each case, said they were nearly identical. One of the mothers had adopted the remedy of teething powders three times before, and with success. There was no evidence that the powders had been tampered with. Then, as to the effect of the powders, in each case they had evidence of narcotic poison. He referred to the symptoms of each child, and read portions of the evidence to show the immediate effect of the powders. Then came the question, Did the powders in each case cause the death of the children? There was no getting from the fact that each child took similar powders, and all were affected in the same way; but they must make exception in the case of Adams, as the child was suffering from convulsions, and had a convulsive fit before taking the teething powder. Thus, it was very difficult to say whether that child died from narcotic poison or a fit. The question was, first, whether the powders had anything to do with the cause of death; secondly, whether these powders were made up according to the ordinary formula, or whether anything crept into them at their composition of a poisonous nature. The evidence as to the making up and selling of the powders was not so complete as they could have wished. Neither Mr. Lasham nor his assistant knew at what time or by whom these powders were made up. If one person had been in the habit of making them up, it would have been an easy thing to have found it out. He then went into the question of what constituted manslaughter, and explained the law on the subject at some length. Negligence or rashness were criminal to that extent, but if a party acted to the best of his judgment in the discharge of a duty he could not be found guilty of manslaughter. They had no evidence of gross negligence, and must not run away from the facts. If from the medical evidence they were satisfied the children died from the effects of the powders, still they had no proof at what time or by whom such powders were made up. In conclusion, he earnestly begged of them to dismiss from their minds anything they might have heard out of the court respecting the cases, and to confine themselves to the questions whether the powders were the cause of death, or of how or in what manner they were sold or administered.

The jury retired for nearly half an hour, when they returned with the following verdict: "We find that Reginald Copsey, Sarah Jane Keeble, Joseph Brazier, and Septimus Adams died from the effects of a narcotic poison, such poison being contained in powders purchased at Mr. Lasham's establishment, but there is no evidence before us as to how or by whom such powders were prepared."

Suicide of a Chemist and Druggist's Apprentice.

The *Stamford Mercury* reports that on the 22nd October, the body of Samuel Goward Bailey, aged 19, apprentice to a chemist and druggist, was found lying on the terrace in the grounds of Nottingham Castle. A note was found in his pocket asking that his dead body might be sent to his uncle, who is also a chemist and druggist. At the inquest medical evidence was given that death had resulted from a dose of prussic acid. No satisfactory evidence was given as to the state of deceased's mind, and the jury therefore returned an open verdict.

Trade Mark Prosecution.—Apollinaris Water.

At the Lambeth Police-court, on Thursday, November 5, Mr. Eugene Fisher, mineral water manufacturer, of Park-road, Camberwell, appeared to an adjourned summons taken out against him by Mr. Stanley Power Wilkinson, secretary of the Apollinaris Company (Limited), for having, on the 8th day of September, with intend to defraud, unlawfully enclosed a certain article—to wit, mineral water—in certain bottles having thereon the trade mark of the Apollinaris Company.—Mr. George Lewis appeared for the prosecution, and Mr. Douglas Straight for the defendant. The particulars of this case have already been reported, but some further evidence was now given.—John Easton, a lad who was formerly in the defendant's employ, said he remembered washing bottles with a large label of the Apollinaris Company. The defendant ordered him to wash the bottles. Sometimes the labels came off, and then they were put on the rack to dry. When they were dried they were given to Donahugh to put on the bottles again. Had seen the same bottles filled and corked.—John George Cantrell said he was in defendant's employ about two years, and left on the 11th August last. He took proceedings for assault against defendant, and the latter afterwards indicted him for perjury. Witness was acquitted. It was after the charge of assault that he made a statement to the Apollinaris Company. Whilst in defendant's employ he saw a great number of empty Apollinaris bottles on the premises, and also saw a great number filled. Defendant gave instructions to wash the bottles, and if the labels were crumpled they were to be taken off and put on straight. He had seen the bottles filled from a machine on the premises, and sometimes by defendant himself. There was a solution put in the bottles. Some further evidence was given as to sales.—Mr. Lewis, replying to Mr. Straight, said if it was admitted that a certain water was put into the bottles which was not Apollinaris Water it would be sufficient for the case.—Mr. Straight said the water was supplied as Apollinaris Water, because Mr. Fisher in good faith believed it was so.—Mr. Ellison said, considering the late period of the day, the case would have to be adjourned. —Mr. Alfred E. Copp, solicitor, said he wished to state that he appeared to watch the case on behalf of E. Fisher and Company (Limited). The defendant, Mr. Fisher, was the managing director of that company, but the offence with which he was charged was anterior to the date of the incorporation of the company, and therefore before he was their servant.—*Standard.*

Obituary.

THOMAS ANDERSON, M.D., F.R.S.E., etc.

We regret to have to record the death, on Monday last, of Dr. Thomas Anderson, late Professor of Chemistry in the University of Glasgow. Dr. Anderson was born in 1819, and was educated at the University of Edinburgh. On leaving college he visited Stockholm, where he studied for some time under Berzelius, and afterwards went to Giessen and studied under Liebig. Returning to Edinburgh, he acquired considerable reputation by teaching chemistry in the Extra Academic Medical School at Edinburgh, and whilst so engaged received the appointment of Consulting Chemist to the Highland and Agricultural Society. In 1852 he succeeded Dr. Thomas Thomson as Professor of Chemistry in the University of Glasgow, and discharged the duties of the chair with great acceptance until 1869, when he was incapacitated for work by a paralytic seizure. Having had another attack of paralysis in May of the present year, Dr. Anderson, under medical advice to remove further south, went to reside at Chiswick, near London. He therefore resigned his professorship in July last, the class having been conducted in the meanwhile by Mr. Ferguson, who was one of his own pupils, and who received the appointment to succeed him. Dr. Anderson remained at Chiswick until his death. He leaves a widow and two sons.

Dr. Anderson was the author of several papers on the organic bases, especially those bases obtained from opium and coal tar and in the destructive distillation of animal substances. In a paper on the "Chemistry of Opium," read before the Chemical Society in 1862, he described a valuable method of extracting the alkaloids of opium, and determining their relative qualities.

EDWIN LANKESTER, M.D., F.R.S.

On Friday, October 30, Dr. Lankester, the Coroner for Central Middlesex, died from diabetes, at Margate. Dr. Lankester was well known as a writer on scientific subjects, and, in former years, upon medical reform. Born in 1814, at Melton, in Suffolk, he entered University College, London, as a medical student in 1834, and three years afterwards became a Member of the Royal College of Surgeons and a Licentiate of the Apothecaries Company. In 1839 he graduated at Heidelberg, and in 1845 was elected a Fellow of the Royal Society. Amongst the appointments Dr. Lankester held at different times were, Lecturer on Materia Medica at St. George's School of Medicine; Professor of Natural History in New College, London; and Examiner in Botany to the Science and Art Department at South Kensington. In 1859 he was President of the Microscopical Society, and for many years he acted as one of the Secretaries of the Biological Section of the British Association.

In 1842, Dr. Lankester delivered a lecture to the Pharmaceutical Society, on the Structure, Affinities, and Medical Properties of the Natural Order Ranunculaceæ, which was reported in the *Pharmaceutical Journal* of that date. In 1859, he lectured to the Liverpool Chemists, Association upon ozone, with experimental illustrations of its nature and properties.

BOOK RECEIVED.

The Worthies of Cumberland.—John Dalton, F.R.S., etc. By Henry Lonsdale, M.D. London: G. Routledge and Sons. 1874. From the Publishers.

Notes and Queries.

[416.] BREWERS' FININGS.—"A Correspondent" would feel obliged to any person for a correct form for making "Brewers' Liquid Finings," not objected to by the Inland Revenue.

[417.] GLYCERINE JELLY FOR MICROSCOPIC MOUNTING.—In the Journal, October 3rd, 1874, Mr. H. Pocklington mentions "Glycerine Jelly" for mounting, or for examining, microscopic objects. Can you inform me how the jelly is made?

[*** Soak any quantity of good clear gelatine in cold water for three or four hours. Pour off the superfluous water, and melt the gelatine at a gentle heat. When melted, filter through flannel, and to the filtrate add an equal quantity of Price's glycerine. The above forms a good firm jelly, requiring little trouble in securing the cover. Other forms of the jelly will be described in an article on the subject which will appear shortly.—ED. PHARM. JOURN.]

NEW APPLICATION OF THE MARSH MALLOW.—According to a statement in the *Garden*, gypsum, mixed with 4 per cent. of powdered marsh mallow root, will harden in about one hour, and can then be sawn or turned, and made into dominoes, dice, etc. With 8 per cent. of marsh mallow, the hardness of the mass is increased, and allows of it being rolled out into thin plates, and painted or polished.

Correspondence.

PHARMACEUTICAL EDUCATION.

Sir,—I see by the Journal of October 31st, that Mr. B. S. Proctor thinks proper to assert that, "a man had better turn grocer than remain for life an Associate of the Pharmaceutic l Society." Now, as this assertion is made without any particular reason being assigned for it, I may perhaps be forgiven if I inquire why the Associates should abandon "an art and a science," and deal in provisions? I may also state that I consider Mr. Proctor's remarks to be a direct insult to a number of gentlemen, who, having obtained the qualification necessary to legally practise their calling, do so in a manner which, if not quite satisfactory to Mr. Proctor, is perfectly so to the public and the medical profession; and many of whom are doubtless as capable of advancing the science as the Professor of Pharmacy to the University of Durham College of Medicine; for, after carefully reading his communication, I have arrived at the conclusion that, far from elevating the pharmacist in the eyes of any person unconnected with the profession into whose hands it may fall, it will only tend to degrade him, and thus prevent the class of men which the increased stringency of the examinations leads us reasonably to expect from entering the profession.

I trust that some abler pen will lend assistance in removing the ill-effects of Mr. Proctor's remarks.

A. RIVERS WILLRON.

Sir,—Lest it should seem that "silence gives consent," I, as a humble member of the drug trade, would like, with your permission, to utter my earnest protest against some of the opinions expressed in Mr. Proctor's letter of the 22nd ult. This gentleman, who dates from a high northern latitude, bears an honourable name, and may be considered in some small degree a representative man. Moreover, unless I am misinformed, he has written a book, and therefore must only be approached with profound respect. But when he speaks of "that improved pecuniary position" which "can only be accomplished by diminishing the number of those entering the trade," I can only say that such "improved position" had better never be obtained at all than secured by means which may be thought dishonest and unjust.

The attempt to bring about a decrease by any indirect artificial restrictions, such as the manipulation of educational demands, with a view to benefit those who are now in the trade, or may hereafter be admitted to it, apart from the supposed interest of the public, is a nefarious policy, which most educated men of mature age and sound judgment would be ashamed to avow. If such be a fair object, on what ground can we condemn Sheffield rattening, compulsory limitation of apprentices, or the heroic efforts now being made by carpet-weaving men of Kidderminster to prevent the employment of women in their craft? What is there to be deprecated in these or other the hatefullest manifestations of trade-unionism? Is the driving away as many young men as possible from any given business a proper object to be aimed at, or even a consummation to be wished for? In this "renowned island" of Great Britain, with its limited area and ever-increasing population, our most pressing need is that more careers should be opened to industry, not that any of those now existing should be blocked up. Anything which tends in this latter direction should be branded as "contra bonos mores," and "contra salutem publicam." If Swift was right in calling him a benefactor to his race who made two blades of corn grow where only one had grown before, what are we to entitle him who would cut off multitudes of men from an accustomed mode of subsistence?

The "status" argument has been pursued until it has become a weariness; the word jars on the ear. Perhaps it will be found that every one of us gets precisely as much as he deserves—no less, no more. Let each one do his work; perform his daily duties (gratefully remembering there are more degrading occupations than selling "perfumery" and "pickles") with what integrity he may; reward will not be wanting in the way of "status," and otherwise. But all unmanly craving and whining after honour, symptomatic of unwholesome ambition and souls ill at ease, all forms of "which is the greatest" contention, had as well be resolutely avoided for the future; most necessary of all, "respice teipsum."

The comfort which Mr. Proctor administers to the employers who have a difficulty in getting assistants will be felt by those employers to be something worse than a mockery.

The paragraph on the "few hundred rejected students" is one that few readers will peruse without pain. The frame of mind which can enable any man to look with indifference, or, still more, with satisfaction, on the unhappiness and disappointment of his fellow-creatures, is not one to be either admired or envied.

SAMUEL FEAVER.

Truro, November 2, 1874.

"AND OTHER CHOICE CONDIMENTS."

Sir,—The origin of the quotation I have placed at the head of this letter will be easily recognized by the readers of the Journal, and the object of putting it there is to examine its merits. It is part of a statement or declaration by an eminent firm, who claim for it the acceptance of truth, and who have attempted to force its acceptance on the bench of justice. Let us see what is the basis on which this policy is founded. What are the condiments that are asserted to be used in the preparation of the article to which the declaration is attached? Are there any at all? Is turmeric a condiment? or can the addition of a few grains of colouring matter to an ounce of another substance be construed by any force of logic to be the addition of "Choice Condiments"? Let us write the sentence in its naked integrity, and see the difference in its significance:

"Take Notice.

"This preparation is an admixture of pure mustard, with farina and turmeric."

It is not my intention to impute any motive to the members of the firm whence this emanates, for they are all honourable men. But I do think members of Parliamentary Committees ought to be gifted with a keener logic, and a better perception of right and wrong. And, in conclusion, I would just ask whether the statement as it stands is not intended to mislead, or at least to veil over a hidden mystery?

F. M. Rimmington,

Public Analyst for the Borough of Bradford.

"*Spes.*"—(1) Either of the books mentioned are good for the purpose. (2) Any trace of phosphorus that might be dissolved or held in suspension would be oxidized very rapidly.

C. Sinimberghi.—We believe that a solution of peroxide of hydrogen is generally used for the purpose.

E. Bevan.—Apply to the Secretary for a copy of the pamphlet entitled "Hints to Students and Apprentices."

T. T.—We do not know.

J. Priestley.—See p. 379.

Aqua.—There will be no precipitate if the water used be free from earthy salts.

"*At Fault.*"—Such a solution cannot be converted into a dry powder.

W. T.—We cannot say to what the development of a fishy taste in such a mixture would be due. Are you sure that the change takes place, or are you trusting to a statement which might be based upon a patient's fancy?

G. A. Keyworth.—(1) The saline contents of sea-water consist chiefly of sodic, magnesic, potassic, and calcic chlorides and sulphates; also about ·3 gram per litre of bromine; very minute amounts of iodine, fluorine, and silica, phosphoric acid, and calcic and magnesic carbonates in small proportion (Watts, 'Dict. Chem.'), to which list must now be added, according to Sonstadt, gold. The gaseous contents are nitrogen, oxygen, and carbonic anhydride. (2) At the temperature of the oxy-hydrogen flame alumina melts into transparent globules, which assume a crystalline structure (Watts, 'Dict. Chem.') (3) Jourdan gives the following formulæ:—*Decoction*—Miseltoe of the oak, 30 to 60 grams; Water, 2 litres: boil till reduced to one half. *Aqueous Extract*—Miseltoe, 1 part; Water, 3 parts: boil, express, clarify with white of egg, and evaporate. *Vinous Extract*—Miseltoe, 1 part; White Wine, 5 to 6 parts. Digest during three days, boil the marc with a fresh quantity of wine, and evaporate the united liquors. Miseltoe appears, however, to have been more usually used in the form of powder, in conjunction with other substances. Gray (Supplement) says, "leaves anti-epileptic, in doses of ℈j to ʒj twice a day."

"*Guardian.*"—The question is one that should be submitted to a solicitor, as the answer would depend upon the exact terms of the indenture.

"*Nemo.*"—Squibs and crackers are not pharmaceutical preparations, and we have no practical knowledge of their manufacture.

"*Spes.*"—(1) The book you have is a very good one, and sufficient for the purpose; but it is not desirable to limit your study upon any subject to the observations of a single author. (2) The last edition of the book you inquire respecting was published before the 'Additions to the British Pharmacopœia.' (3) No books or notes are allowed, and the examination is confined to one day.

W. D. Williams.—Dynamite is a mixture of nitro-glycerine with silicious matter.

"*Theta.*"—The person mentioned in your communication is not on the Register of Pharmaceutical Chemists. Your letter has therefore been handed to the Registrar.

A Candidate.—Translation of Latin into English, Latin Grammar, English Grammar and Composition, the first four rules of Arithmetic, simple and compound, Vulgar Fractions and Decimals, and a thorough knowledge of the British and Metrical Systems of Weights and Measures.

G. H.—It would be impossible to give advice worth having without a better knowledge of your present acquirements and other circumstances. The "finishing your education for the Minor" ought to take rank as a primary necessity.

Godfrey's Laboratory.—We think our correspondent has mistaken the object of our notice, which was merely to call attention to a matter of antiquarian interest to pharmacists.

"*Pharmacist Major.*"—We cannot agree with you in regarding the prescription you have sent a copy of as being an extraordinary one, excepting so far as it constitutes one of those cases where communication with the prescriber is desirable.

J. McK.—The account you give is exceedingly vague; in fact, wanting in all essential particulars. If the case be one which admits of legal proceedings being taken, and if such action be desirable, we still think it is not a matter to be dealt with by the Pharmaceutical Society, but by a special organization for that purpose.

H. C. Druce.—(1) *Juncus supinus.* (2) *Aira præcox.* (3) *Festuca ovina*, var. *vivipara.* (4) *Cerastium glomeratum.*

The Benevolent Fund Election.—We have received a letter from Mr. H. J. Bellingham, requesting to be allowed to express his warmest thanks and heartfelt gratitude for the kind support which placed him at the head of the poll at the late election of annuitants upon the Benevolent Fund.

We have received from Mr. R. Huggins a specimen of his Ozone Paper.

"*Inquirer.*"—(1) If the salts are mixed and dissolved all together, there may sometimes be a slight separation of quinine, owing to the alkalinity of the potassium iodide. This separation will be less if they are dissolved separately and then mixed. (2) Dissolve the iodide and bicarbonate in about five ounces of the water, and add the quinine, slightly powdered and mixed with the remaining portion of water. The spirit to be poured in last; it will not keep long.

A. P. Metcalfe.—We will endeavour to obtain the information you ask for.

Senior.—Before you will be allowed to enter for the Minor examination you must pass the Preliminary examination of the Pharmaceutical Society, or produce a certificate of having passed at one of the Local examinations of the University of Oxford, Cambridge, or Durham, the examination of the College of Preceptors, or that of any legally constituted examining body previously approved by the Council, provided Latin and Arithmetic are included in the subjects of examination.

Vinum.—A stamp is required upon any box or bottle containing a "secret or occult preparation," or one which is stated to be prepared only by the person whose name it bears, or one which is recommended by label, handbill, or advertisement for the cure or relief of any disorder.

"*Apprentice.*"—Apply to the Secretary, 17, Bloomsbury Square, for a copy of the Regulations of the Board of Examiners.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

Communications, Letters, etc., have been received from Mr. Jackson, Mr. Brown, Mr. Anthony Smith, Mr. W. B. Hemsley, Mr. Mount, J. E. M., T. C. B. K., "Inquirer."

The following journals have been received:—The 'British Medical Journal,' Oct. 31; the 'Medical Times and Gazette,' Oct. 31; the 'Lancet,' Oct. 31; the 'London Medical Record,' Oct. 31; 'Medical Press and Circular,' Oct. 31; 'Nature,' Oct. 31; 'Chemical News,' Oct. 31; 'Gardeners' Chronicle,' Oct. 31; the 'Grocer,' Oct. 31; 'Journal of the Society of Arts,' Oct. 31; 'Grocery News,' Oct. 31; 'Produce Markets Review,' Oct. 31; 'Practical Magazine,' for November; 'Educational Times,' for November; 'British Journal of Dental Science,' for November; 'Journal of Applied Science,' for November; 'Canadian Pharmaceutical Journal,' for October; 'Tennessee Pharmacal Journal,' for October; 'Moniteur Scientifique,' for October; 'Pharmaceutische Zeitung,' for Oct. 28 and 31; 'Sanitary Record,' Oct. 31.

CALAMINE POWDER.

BY TILBURY FOX, M.D. LOND., F.R.C.P.,

Physician to the Department for Skin Diseases in University College Hospital.

I wish to offer a few remarks upon the use of calamine powder—a subject referred to in the columns of the *Pharmaceutical Journal* some little time since. In a review which appeared of the University College Hospital Pharmacopœia, the combination of calamine powder with ordinary oxide of zinc powder in lotions was noticed as a strange one. Several writers subsequently referred to the subject from a therapeutic point of view, and also to variations in the physical characters of calamine powders in general use in dispensaries. Now, as regards the first point—the combination of calamine powder with other zinc preparations—I will only say that its propriety is, of course, a matter for the prescriber to determine. Mr. Martindale sufficiently explained that there was a special reason for this combination, and I therefore say no more about this point, because I am anxious to deal particularly with the other matter, viz., the characters of calamine powders. I desire to define from the point of view of the prescriber what the qualities of the powder are which he regards as most desirable. I have a particular interest in this little matter, for I suppose I use calamine powder more largely than any one else, now that Mr. Startin is no longer with us. My object is to induce pharmaceutists to come to a common understanding to employ for the future, in all prescriptions, calamine powder of a certain colour, of special physical characters, and to discard once and for ever the old-fashioned dirty red, gritty powder of the shops.

I find that sometimes my patients get from the same prescription, made at different places, a pale-coloured and soft lotion, and sometimes a brick-dust coloured, gritty, and irritating lotion, the latter compound now and then doing harm.

The following should be the properties of the calamine powder of which I approve:—

1. Its colour should be very pale salmon, or pale flesh-coloured. This kind of calamine powder will vary somewhat in shade, but with care it can be prepared of the desired hue. This colour should not be artificially induced.

2. It should not be coarse, nor gritty, nor sandy feeling *in the least degree*, when rubbed between the fingers. I remember being shown a sample of calamine powder at one of the best pharmaceutical establishments in London, which had been prepared with great care and some expense, and I gave some offence on saying that it was not so fine as I liked it. But so it was.

3. It should be such a powder as will not leave behind in the mortar, on making up a lotion with it, any gritty particles.

Now, calamine powder possessing these characters must be real calamine powder, as I have before hinted. It must not be oxide of zinc, coloured with iron or bisulphuret of mercury. It can be prepared from the rougher, or common calamine powder, by repeated incinerations, levigations, and subsidences. It may take a long time to prepare, but I know it can be made.

I may just say, however, that in making up a lotion with calamine powder in it, it is important to rub up the powder with the other ingredients in a mortar carefully, so as to be quite sure no lumps or sandy particles get into the lotion.

Lastly, in regard to the character of the lotion when made up, it should be such as to leave behind, when dabbed on to the skin, a very fine, soft, powdery layer. If the lotion be not of this nature, then it will, in many cases, act as a positive irritant, in consequence of the action of the gritty particles upon the delicate and sensitive surface—mostly of an inflamed face—to which it is applied.

All this is quite well known to some pharmaceutists, but not to all, and those who know it will, I feel sure, be only too desirous to second the attempt to bring about a common understanding as to what is meant by calamine powder by the prescriber. There is a practice in vogue of naming particular pharmaceutists for this or that particular drug, for which I think little reason ought to exist. I hope pharmaceutists will take away every vestige of excuse for it, touching calamine powder, by adopting my suggestion to discard the ordinary red gritty powder, which is more fit for use as "ruddle," or the facial adornment of itinerant "fire-eaters," than anything else.

*** In reference to this subject see a note read by Mr. R. Reynolds at the British Pharmaceutical Conference in 1870 (*Pharm. Journ.* [3], vol. i., p. 434). It will there be noted that the defect pointed out by Dr. Fox arises more from the nature of the material used as calamine than from any imperfection in its preparation. If Mr. Martindale's explanation of the use of calamine be sufficient, probably the physician's object would be best attained by using an artificial carbonate of zinc, with just enough "red oxide of iron" to give it the correct tint.—ED. PH. JOURN.

WHAT ARE THE QUALIFICATIONS WHICH CONSTITUTE A GOOD DISPENSER?

BY A. F. HASELDEN, F.L.S.

This may at first seem a very simple question and easily answered, but a little consideration may probably show that the qualifications of a good dispenser, from a business point of view, are not so readily set down, or so easily acquired. My object is not to contest any opinion, but from my own experience to shadow forth the qualifications which should be possessed by a good practical pharmaceutical dispenser, and at the same time to advert to some of the difficulties he will have to contend with. I will not say that he must have passed his Minor Pharmaceutical Examination, for that alone will not stamp him a practical dispenser, although many justly attach considerable importance to the fact of having done so.

As soon as a prescription is placed in the hand of a pharmaceutist, whether it will be his duty to dispense it himself, or give it over to *the* dispenser of the establishment, a quick eye should readily scan it over and perceive whether it is for mixture, draught, liniment, lotion, ointment, suppositories, or pills. A ready reply should be forthcoming to the questions such as how long it will last, how long keep good, and how long take to prepare? for upon the replies frequently depend the quantity to be made up, whether it will be waited for, or whether it must be sent, and not less often, whether it is to be made up at all. In addition, it is not uncommon that the pharmaceutist is supposed to know for what complaint the prescription has been written, and if it is likely to be beneficial. With this as a dispenser he has really nothing to do; nevertheless, as a man of business, he must be able to reply without indifference, and at the same time without committing himself to a possible error. I may quote the advice given by a physician to myself upon this very point, "*Say enough, but in reality tell nothing*; but it would scarcely do in these enlightened times to reply to an inquiry concerning some drug, *that it came from foreign parts.*

Having disposed of any preliminary of this nature, he will place the prescription before him, read through the whole, even to the name of the patient, the date, and the initial, or name in full, as the case may be, of the prescriber, and this, for obvious reasons. Should there be draughts (though now few and far between), the direction of how often will imply how many; equally so with pills, should the number not be stated; also he will see if they are to be coated or silvered. If single-handed, he will then write the direction and copy the prescription. I have said he will read over the prescriber's name or initials, because, if conversant with his style of prescribing, he will the more readily know what he requires; whether, for instance, in mixtures the exact quantity of fluid menstruum ordered is to be put in (making sometimes an uneven measure), or made up to 4, 6, or 8 ounces, as the case may be. The same remarks apply to liniments and lotions, and sometimes whether they should be strained or filtered, or sent out thick, or with particles floating about. The next point he will observe, if he be practical as well as careful, is the order in which he intends to mix the several items in a compound. This is often very important, as experience teaches that the order of mixing ofttimes much influences the appearance. He will be particular in reading the labels of the bottles, etc., from which he takes the articles, not trusting to the bottle or jar being in a particular spot; and if there be any precaution of fastening or tying over, will attend to it before replacing the bottle or pot. He will not put preparations of ether, ammonia, hydrocyanic acid, and the like into the bottle before the other ingredients forming the mixture, lotion, or liniment. He will naturally count the pills before boxing them, to ascertain that he has divided the mass into the proper number, and has not dropped one or more upon the floor—such a thing has happened and may happen again. After reading and affixing the labels he will re-read the prescription, to be sure that all is correctly done. If there be anything of an unusually potent nature in the prescription he will bear the dose in mind. Should suppositories or pessaries form part or the whole of the prescription, he will know that, unless they are of a character kept in stock, they cannot be prepared in a quarter of an hour; that in summer weather it is necessary to have ice upon which to place the mould, in order to cool them, and that soft soap is the best thing to smear upon the mould to prevent them sticking. In addition to the care, etc., attending the preparation of the medicines, he will also have to arrange for sending them out as to time, and this is often no slight matter, if the distance be far and the time short. [Here let me say that porterage should in many instances be charged for, when we reflect that a commissionaire never moves under sixpence.] Where two or more assistants are employed it is an excellent arrangement that one should prepare the medicines and another write the directions, check the articles, and send them out, thus reducing the liability of error and relieving to some extent the anxiety of the compounder.

Thus far, supposing the medicines prescribed to be tenants of the B. P., it has been pretty plain sailing, which a careful, thoughtful, practical young man with a head upon his shoulders will have no difficulty in carrying out. Let us now turn to some of the difficulties he has to contend with. It frequently happens, and generally when most occupied, that some preparation forming part of the prescription is not in the B. P., nor in the late P. L., and without being a Pil. Philip., or the established preparation of some well-known firm, with, as is often the case, the name attached, it really hails from our neighbours across the Atlantic; as, for example, see the following:—

℞	Tinct. Guaiaci C.	ʒiij.
	Potas. Iodidi	℈j.
	Tinct. Gelsemini	ʒiij.
	Mucil. Acaciæ	ʒiij.
	Aquæ ad.	℥iij.

Sit dosis coch. j parv., ex aquæ cyatho.

Here in the Tinct. Gelsemini is an American preparation of the *Gelseminum sempervirens*, popularly known as yellow jessamine, wild jessamine, woodbine, etc., the part used being the bark of the root; an account of it will be found in the *Pharmaceutical Journal*, p. 998, vol. iv., present series. Now, supposing the dispenser reads as he should, and probably does, the notes upon new remedies and preparations, he can scarcely be expected to remember them all; but the good practical man will think, and in all probability search the 'Journal of the Pharmaceutical Society' (to which Society it is hoped he belongs), where he is more likely to find the required information than in any other book within his reach. Without multiplying examples of these preparations, which might readily be done, or enlarging upon unusual English prescriptions, many of which present great difficulty in dispensing, specimens of which may be found under the heading "Dispensing" plentifully scattered through the last three or four volumes of the Journal. The following, coming from foreign sources, may be put forward as explanatory of what also a dispenser may be expected to know:—

℞ Flor. Anthem. . . . . . . 2 decagrammes.
Aq. Ferventis . . . . . . 1 litre.
Macera donec frigid. sit tunc cola et adde
Magnes. Calcinat . . . . 4 grammes.
" Sulphat . . . . . 3 decagrs. M. & Sit.

Or thus—

Mistura :—
℞ Tinc. Chinæ Comp. . . . . ℥iv.
Capiat coch. min. 4^tis horis ex aquâ.

The translation or preparation of this is as follows:—

℞	Cort. Chinæ fusci	partes 6.
	" Fruct. Aurant	" 2.
	Rad. Gentian.	" 2.
	Cort. Cinnamomi Cassiæ	" 1.

E contusis et concisis
Spiritûs diluti. . . . . partes 50.

A tincture is now to be prepared by digestion, but if required quickly it may be made by percolation. Again:—

℞ Tinct. tonico-nervinæ Bestuscheffii . . . ℥iv.
Capiat guttas xv., ex aquâ 4^ter indies.

The meaning of this is an ethereal tincture of chloride of iron. There is no difficulty in these if it is known where to look for the information; but, on the other hand, highly inconvenient if it is not readily obtained. One word of advice upon this question. If there be a doubt which cannot be solved, say so to your customer; but never substitute one thing for another. Honesty in this as in other affairs is the best policy, and will endure the longest. Having so far expressed my views of the qualifications necessary and expected in a good dispenser, may I suggest one other question, and here 's the rub—how is a good dispenser made? Not by mere bookwork; not by three or four years' apprenticeship; but by time, diligence, instruction, opportunity, and practice; these will accomplish the end. One word for the young who are not yet practical dispensers. Let them be cautioned against the assumption that, because they did not fail at the examiner's dispensing counter, *ergo* they are good dispensers. Let them work carefully as juniors, and gradually take the higher place, remembering from day to day that there is always something to be learnt, and that now, as in the days of the Athenians of old, the cry is still "Something new! something new!"

ACTION OF SUNLIGHT UPON IODIDE OF POTASSIUM.*

BY M. VIDAU.

Early in the morning of the 14th August, the author, having to prepare for use in the pharmacy a ten per cent. solution of iodide of potassium, placed 50 grams of the iodide in a glass funnel plugged with cotton, and poured upon the salt about 500 grams of water taken from a cistern supplied by rain water. The liquid filtering through the cotton plug ran perfectly limpid into a flask placed by chance upon the ledge of an open window strongly lighted by the rays of an African sun. After a short time it was noticed that the liquid contained in the flask formed into two layers, very distinctly marked by the difference in their colour: the lower composed of a concentrated solution of iodide of potassium, and already perceptibly coloured yellow; the upper, occupying at least three-fourths of the total volume, consisting of a dilute saline solution, and quite colourless. When these layers were mixed by agitation a perfectly colourless liquor was obtained, which had no action upon starch mucilage.

The circumstances suggested that solar light might be the cause of this difference of colour, produced by the setting free of iodine through the decomposition of the iodide, and led to the following experiments:—

Two white 60-gram phials were filled with a ten per cent. solution of iodide of potassium (phials 1 and 2). Into a third phial was poured a solution of twenty grams of iodide in twenty grams of water. Both the solutions were very alkaline. Phials 1 and 3, carefully closed, were, at 8 a.m., placed in full sunlight near to a whitened wall facing the sea; phial 2 was wrapped in ordinary yellow paper, and placed in the shade. At 8·30 the contents of phial 3 had already become perceptibly yellow, but at 10·30 no change was apparent in phial 1. At 2 p.m. phial 1 was tinged very slightly yellow; 2 was quite colourless; 3 was of a yellow colour similar to that of almond oil. With recently prepared starch mucilage the liquid in No. 3 gave a violet colour, and formed almost immediately a very deep violet coloured precipitate. Seen under the microscope some starch grains were coloured deep violet with the contents of No. 3. With the contents of No. 1 starch mucilage showed no very appreciable change; with the contents of No. 2 it gave no coloration.

* Read before the Paris Société de Pharmacie. See the discussion reported on p. 393 of the present number.

The liquid in all three phials was then rendered slightly acid by the addition of a few drops of acetic acid (which caused an evolution of carbonic acid gas), and Nos. 1 and 3 were at 3 p.m. again exposed to the action of sunlight; No. 2 was enveloped in a double wrapper of blue and yellow papers, and placed in a kind of recess, but kept at the same temperature as the others. At 4 p.m. No. 3 had browned very perceptibly. No. 1 had acquired the colour which No. 3 had when the acid was added; No. 2 was unaltered. The next morning the yellow colour of No. 1 was very manifest, and the liquid gave immediately a violet precipitate with starch mucilage. The yellow colour in No. 2 was not very evident, but the commencement of decomposition was shown, though very slightly, by starch mucilage. No. 3 was of a deep brown colour, and the free iodine was detected with facility with starch mucilage or carbon bisulphide.

The action of sunlight upon the solution of iodide of potassium would appear to be thus placed beyond doubt. It seems evident that if atmospheric ozone alone caused the decomposition of the iodide there would be no reason why this action should not have occurred with equal intensity in the phial kept in the shade and that exposed to the sunlight. The action of the sunlight appears the more energetic in proportion as (1) the solution is more concentrated, and (2) the solution is less alkaline. It is advisable, in fact, in making these experiments to use a neutral solution, since any iodine set free by the action of sunlight in an alkaline solution enters afresh into combination with the excess of alkali, and so is not manifested by the colouring of the liquid or detected by the reagents. In a very concentrated solution, however (equal parts of iodide and water), the alkalinity does not prevent a partial decomposition.

Experiments with Paper saturated with Iodide of Potassium and Starch.

Experiment 1.—Three slips of white paper were steeped in a solution of neutral iodide of potassium, then in fresh starch mucilage; the slips were enclosed, while still damp and quite white, in three carefully-washed phials, which were then hermetically sealed.

Phial No. 1, white glass.—Exposed to the sun's rays during one hour, the paper took a rather dark violet colour.

Phial No. 2, white glass.—Enveloped in two papers, one white and the other blue, and kept in the shade; at the expiration of an hour there was no trace of coloration of the paper.

Phial No. 3, blue glass.—Placed in the same conditions as No. 2, and gave the same negative result.

Experiment 2.—A square of white paper, upon which had been spread a coat of iodide solution and a coat of starch mucilage, was put while still wet into a kind of photographic frame between two papers blackened on the outside. From the side exposed to the light, designs of a cross and a circle were cut. After a short exposure, the iodized paper presented the designs of the cross and the circle in violet, whilst the remainder of the paper remained white.

Experiment 3.—The iodized paper, instead of being exposed to the sun's rays, was placed where only a faint light reached it. In this case the iodide of potassium was decomposed much less energetically than in any of the other experiments.

Experiment 4.—White filtering paper was dipped in a dilute solution of tartaric acid, then dried, and afterwards made to absorb successively starch mucilage and solution of iodide of potassium. It was then again dried in a cupboard well closed from the sun's rays. The paper so prepared was extremely sensitive to the action of light. When dry, it was cut into slips and put dry into three phials, under conditions similar to those in the previous experiments. The result was nearly identical, except that the bands in Nos. 2 and 3 were no longer quite white at the conclusion of the experiment, but had acquired a slight violet tint, whilst the slip in No. 1, exposed to the light, became of a deep violet colour.

Experiment 5.—The dried bands impregnated with a solution of tartaric acid and starch mucilage were moistened by dipping them into a solution of iodide of potassium, and put wet, and quite colourless, into three phials. No. 1 was exposed to the light, Nos. 2 and 3 were covered and kept in the shade. In No. 1 the band became intensely coloured, in Nos. 2 and 3 the colouring was scarcely perceptible.

From these experiments the author concludes that iodide of potassium is rapidly affected by sunlight under the most diverse conditions. M. Cloez has already published results of experiments tending to show that in certain circumstances the change in the colour of paper saturated with iodide of potassium and starch ought not to be attributed to the action of ozone, but rather to that of sunlight. It would appear, therefore, that all testings for atmospheric ozone by the setting free of iodine from iodide of potassium,—indicated either by the colouring of a paper saturated with iodide of potassium and starch, or the alkaline reaction on litmus paper, showing the decomposition of the iodide,—are liable to be vitiated by grave causes of error, for in thus estimating the ozone contained in the air the operator at the same time measures the intensity of the sunlight in the medium surrounding the test papers, which are affected by both causes.

ORGANIC BASES.*

Although bodies having the properties of acids—as, for instance, tartaric, citric, and malic acids—had long been known to exist in certain vegetable and animal substances, it was reserved for our century to discover bodies of alkaline or basic properties in the organic world. A chemist, Sertürner by name, first succeeded in isolating morphine from opium, the long-known juice of the poppy, obtained by making incisions in the capsules, and afterwards drying the product in the air.

Little attention was at first paid to this discovery, because all the energies of chemists had been turned to the study of inorganic chemistry; it was out of the regular line of research at the time, and, therefore, remained isolated and unappreciated. When, however, several years later, Gay Lussac showed the importance of Sertürner's discovery, and proved himself, in a dissertation published in 1816, that morphine acted like an alkali in regard to vegetable colours and acids, his work became the incentive to a search for similar bodies in such plants as were known for their sanative or poisonous effects. In many cases their active principle was found to consist in an alkaline substance, combined with an organic acid, and hence called an alkaloid.

Pelletier and Caventou found alkaloids in Peruvian bark and in the Strychnaceæ, and in 1826 Unverdorben succeeded in artificially preparing several alkaloids or organic bases by the dry distillation of horn, bones, and other animal substances. These discoveries gained for organic bases a place among the most important and interesting bodies in chemistry, and many chemists devoted themselves exclusively to their study. Theoretical considerations concerning the nature of organic bases caused their more extended investigation. These theoretical considerations were founded upon the interesting fact of the similarity of all these bases to ammonia. In the natural alkaloids the similarity consists chiefly in the chemical equivalents, but in the artificial bases lately discovered it is also exhibited in their physical properties.

These facts have led to the supposition that there exists an intimate relation between the organic bases and ammonia. Berzelius, indeed, suggested the probability of the pre-existence of ammonia in all these bases; while Liebig, in the first volume of his 'Dictionary of Chemistry' ('Handwörterbuch der Chemie'), developed a theory concerning their constitution, which forms the basis of our present views as to this interesting branch of chemistry. He assumed that ammonia was the type of all organic bases, and that it was itself such a base, of the simplest composition. Ammonia consists of only two elements, containing one atom of nitrogen and three of hydrogen in one molecule. Liebig assumed that, in the organic bases, a part of the hydrogen was replaced by other radicals, composed of several elements; these bases might therefore be considered as made up of a compound radical and a combination of one atom of nitrogen with only two of hydrogen, the other atom of hydrogen being replaced by the new radical. The compound thus formed is called amid.* Such a base is called an amid base.†

Liebig developed this idea in the clear and ingenious manner peculiar to himself, and expressed his views concerning the probable nature of compounds which could be formed from amid and the alcohol radicals. Ten years later his ideas were verified by experiment. Ethylamine, and a whole series of similar bases, were produced by Würtz, in Paris, in 1849.

These discoveries of the celebrated French scientist justly excited unusual attention, which was still increased when A. W. Hofmann and Würtz demonstrated that not only one atom of hydrogen in ammonia could be replaced by an alcohol radical to form amid bases, but that compound radicals could be substituted for two, and even for all three, atoms of hydrogen. These bases might be designated as primary, secondary, and tertiary amid bases, according as one, two, or three atoms of hydrogen of the ammonia have been replaced by compound radicals. (In English treatises on chemistry they are usually designated as amid, imid, and nitril bases.—*The Translator.*) Their chemical formulæ are represented by the following table, in which A, B, C stand for the compound radicals:—

Ammonia base.	Amid base.	Imid base.	Nitril base.
$\left.\begin{matrix}H\\H\\H\end{matrix}\right\}N$	$\left.\begin{matrix}A\\H\\H\end{matrix}\right\}N$	$\left.\begin{matrix}A\\B\\H\end{matrix}\right\}N$	$\left.\begin{matrix}A\\B\\C\end{matrix}\right\}N$

As Hofmann has shown later that there is a series of compound radicals which may replace two atoms of hydrogen in the doubled formula of ammonia, producing a second extensive series of bases, whose composition is expressed in the following table, where A_1 B_1 and C_1 represent the compound radicals:—

$$\left.\begin{matrix}H_2\\H_2\\H_2\end{matrix}\right\}N_2 \qquad \left.\begin{matrix}A_1\\H_2\\H_2\end{matrix}\right\}N_2 \qquad \left.\begin{matrix}A_1\\B_1\\H_2\end{matrix}\right\}N_2 \qquad \left.\begin{matrix}A_1\\B_1\\C_1\end{matrix}\right\}N_2$$

If we suppose only 52 such compound radicals capable of replacing one atom, and 32 of replacing two atoms of hydrogen, we obtain 35,000 millions of possible compound organic bases.

This enormous number shows how impossible it is, in spite of the most persevering labours, to become acquainted with more than a very small proportion of these com-

* Lecture delivered by Professor A. Bauer before the Vienna Society for the Diffusion of Scientific Knowledge. From the Report of the Smithsonian Institution.

* The chemical formula of amid is therefore: H_2 N.

† The formula for an amidogen base is: $A+H_2N$, in which A stands for a compound radical.

pounds. This very number urges us to study only the prominent representatives of whole series, and to give to them our whole time and energies.

From what has been said in regard to the composition of organic bases, it was thought evident that nitrogen would appear to be the component on which their properties depend, for they all contain nitrogen. But we know now whole series of analogous bases containing, instead of nitrogen, some other element of similar properties. These also have the characteristics of ammonia. As early as 1846, Paul Thenard had made phosphorus bases, which were more thoroughly investigated in 1855 by Hofmann and Cahours. Analogous arsenic bases have been known much longer. In 1760 Cadet prepared one, the composition of which he could not, of course, explain. The investigations of Bunsen, from 1837 to 1843, shed more light on this remarkable class of organic bodies, and the constitution of the arsenic bases was finally completely made clear by the researches of Cahours, Kolbe, Riche, and especially Baeyer, in Berlin. In 1850 Löwig discovered antimony and bismuth bases, so that we now have four other elements capable of forming whole series of basic combinations like those of nitrogen. Compare these with the above-mentioned number of possible nitrogen bases, and we must be convinced that the chemist as well as the astronomer is able to astonish us with magnificent numbers, and to call up before the mind's eye endless series of possible combinations, all producing bodies having special qualities.

However much these researches have extended our knowledge, they have but slightly improved our acquaintance with the bases and alkaloids spontaneously formed in nature. The constitution and the relations of these natural alkaloids to the other bases and to other chemical compounds are much less understood than the foregoing statement would lead us to suppose. The causes of this are that the natural alkaloids are mostly very complex bodies, and that they suffer such complete changes in most reactions, that it is difficult to study them, or to form any conclusions as to the constitution they had before they were decomposed. It must be left to the future to shed more light on the nature of these bodies. Let us hope that it will be possible to make those alkaloids synthetically which have hitherto been found only in nature. We must not forget in this connection that most of the natural bases contain oxygen, which is not found in the ammonia bases. Although the discovery of the so-called ammonium bases, and Würtz's beautiful discovery of the behaviour of oxide of ethylene to ammonia, have indicated the way of preparing such oxygen bases artificially, there is nevertheless a difficulty, which seems almost insurmountable. It is the fact that most of the natural bases have optical properties, while we cannot succeed with the aid of the above processes in preparing compounds possessing similar properties from substances not originally possessing them. The discovery of methods for the artificial or synthetic preparation of the alkaloids would not only be of high scientific interest, but it would also greatly advance our material interests, for there is scarcely another group of bodies of such manifold uses as the organic bases.

Many of these alkaloids play an important part in the arts, others are known as the active principles of stimulating articles of food, while the great number of them are valuable as medicines. Many of them are extremely violent poisons, and have acquired an unenviable reputation from cases in which they have been employed.

Poisoning by means of vegetable bases is rendered doubly dangerous, because it is often difficult to prove with certainty the presence of the poison in the corpse or the secretions by chemical analysis, while the presence of mineral poisons can generally be detected with ready certainty. The reason of this is not difficult to understand. We are but imperfectly acquainted with the properties of the natural alkaloids. They resemble each other very much. In cases of poisoning, they are mixed up in the stomach or other parts of the body with many other organic substances, all containing carbon and having certain properties in common with them. These organic substances are of course more akin to the vegetable bases than to inorganic substances, such as the compounds of arsenic, which are not found in any part of the human body. Metals are present only in insignificant quantities, and those which are present are not at all similar to arsenic. Now, the organic bodies present all contain nitrogen, and may have basic properties, both characteristics of alkaloids. It is obvious that the detection and separation of very similar bodies are much more difficult than the separation of dissimilar ones, where the detection of a single property often suffices to prove their presence with certainty.

If we consider furthermore that the alkaloids are very easily decomposed, and that in legal chemical investigations the bodies in which they are to be sought for are generally in a state of putrefaction—*i.e.*, of continual active change—we shall understand how impossible it is frequently for chemists to separate the poisons in a state of purity from parts of the body, and to prove their presence with certainty. It is indeed sometimes possible to inject the substances which in cases of poisoning must contain the vegetable base, into the blood of living animals, or to mix it with their food, and then to judge, from the physiological effects on the animals, which poison was present. The changes produced by certain alkaloids on the beating of the heart, on the general action of the muscles, and on the nervous system are frequently so characteristic that we can judge of the presence of one or other alkaloid with as much certainty from these effects as from pure chemical reactions. Such proofs, however, have not the full force of evidence in court, for in such cases the separation of the pure poison must always be the chief aim of the chemist.

Dangerous as our organic bases may become in the hands of the murderer, they are highly salutary in the prescriptions of the physician, who employs them with great success in the treatment of severe and otherwise unyielding diseases. Peruvian bark owes its efficacy to the alkaloid *quinine* which it contains, together with *cinchonine* and *chinidine* in varying proportions. Formerly, before these facts were known, there was no standard by which the value of different specimens of Peruvian bark could be correctly judged. Sometimes a certain kind of bark, whose dose had been fixed by experience, acquired a much greater value than others whose efficacy far surpassed it. Now the value depends on the amount of bases contained in the bark, and not on the colour, shape, or other external signs. Not the smallest piece of the bark is now allowed to be lost on gathering it, because processes are known by which even the smallest quantity of quinine contained in it can be obtained.

The same is true of different kinds of opium. Their medicinal value depends on the amount of alkaloids they contain. These are *morphine*, *codeine*, and *narcotine*, three beautiful crystallizable bodies, the latter of which is distinguished by the peculiar property of furnishing another base, *trimethylamine*, when mixed with soda-lime and subjected to dry distillation. Chemists have proved the presence of trimethylamine in the pickle of herrings. It is the cause of their peculiar odour. Urine contains it also in small quantities, hence the smell of herrings when much of it is evaporated down. The *belladonna* and the *Datura strammonium* contain the alkaloid *atropine*, whose terribly poisonous properties are generally known, but which plays a very important part in treating diseases of the eye. Applied to the eye in a dilute state, or rubbed into the skin near the eye, it powerfully dilates the pupil, and greatly facilitates certain operations on that organ. From all parts of the hemlock a colourless, transparent oil, of penetrating odour, can be obtained, which is known under the name of *coniine*, and is one of the most poisonous alkaloids. Either this or *cicutine*, contained in the water-hemlock, was the cause of the tragical death of Socrates. In the St. Ignatius bean and the nux vomica, *strychnine* is found along with *brucine;* it forms a beautiful crystallizable alkaloid, distinguished by its extremely bitter taste, and by its producing tetanic spasms when injected into the blood.

To this class of organic bases belong also those poisons which savages use for steeping the points of their arrows. There are undoubtedly several such poisons. It seems that the one used by the savages of India and Africa is essentially different from that used by the natives in the northern part of South America. The former, called *antia*, immediately stops the beating of the heart, while the latter, called *curare*, first palsies the general muscular action, and then stops the heart. *Curare* is the better known of the two; it was first brought to Europe by Sir Walter Raleigh, in 1595. According to Humboldt, the preparation of this poison resembles our vintage feast. The savages collect poisonous vines in the forest, while the women prepare an intoxicating fermented liquor, of which they all partake. When all are intoxicated and lie in deep sleep, the master of the art prepares the poison by extracting the juice of the vines, and evaporating it down. Different travellers agree that they also add poisonous ants and fangs of snakes. It would seem, therefore, that *curarin*, the active principle of the arrow-poison, or curare, was a constituent of the juice of vines; but there is no certainty on this subject, since travellers do not agree in their accounts of the preparation of this interesting substance. Curare can be taken into the alimentary canal without the slightest danger, and even the meat of animals poisoned by it is innocuous, while it is certainly and often suddenly fatal when injected into the blood even in small quantity. When introduced into a wound, this poison occasions no pain whatever. The symptoms preceding death are very remarkable, as can be seen when a very small quantity is introduced into the blood of a large animal. There is an immediate relaxation of the muscles, all voluntary motion ceases, the animal sinks down powerless, but with its consciousness unimpaired, and finally the respiration ceases and death ensues, without the presence of any symptoms which would indicate excitement or a death-struggle. It is a progressive palsy, ending in the brain.

A whole series of organic bases is esteemed on account of the pleasant stimulating effect they exert on the body when in small quantities and diluted with other substances. They belong to the category of luxuries. Among them, *nicotine*, the active principle of tobacco, takes the foremost rank.

Pure nicotine is a liquid, which becomes brown in the light, has a tobacco-like smell, and possesses very poisonous properties. The amount of nicotine contained in different kinds of tobacco varies. Although it is not exactly in the inverse, it is by no means in direct proportion to the excellence of the tobacco. Fine brands, such as Havana and Maryland tobaccoes, contain but very little; the former not quite two and the latter from two to four per cent. Kentucky and Virginia brands contain as much as from six to seven per cent., and some of the domestic brands of Germany contain considerable quantities.

Besides nicotine, there are some other bitter principles contained in tobacco, which are the chief cause of nausea in young smokers. These are kept back by smoking pipes with long stems, which only allow the gaseous bodies to reach the mouth. Besides carbonic acid and carbonic oxide, tobacco smoke often contains as much as 3 per cent. of carbonate of ammonia (which causes the increased secretion of saliva), and also butyric acid, empyreumatic oils and resins, traces of sulphuretted hydrogen, and even prussic acid, but no *creosote*.

Pepper owes its pungent taste to *piperine*, a crystallizable alkaloid. Tea and coffee both contain the same organic base, theine or caffeine, which are easily obtained from them in silky needles. A solution of this alkaloid neither has the taste nor the pleasant stimulating effect of an infusion of tea or coffee. In these beverages, as in tobacco, the value of the article used depends on other substances which accompany the alkaloid.

Chocolate owes its value to *theobromine*, an alkaloid contained in cacao. It has been lately found that iodide of methyl digested with theobromine for some time in a sealed tube, at the temperature of boiling water, will convert it into theine.

The excellent effect of pure meat broth on the system is due to kreatine and kreatinine, two bases contained in meat. Broth, therefore, belongs to the same class as tea, coffee, and chocolate, and it certainly deserves the preference when the system of the sick person requires a stimulating and strengthening beverage.

Some organic bases have obtained a prominent place in the chemical arts. It is only necessary to mention *kyanole* or *aniline*, which is obtained in large quantities from coal-tar, and is used in the manufacture of the finest colours. Aniline red is the chloride or acetate of rosaniline, a colourless base obtained from aniline. Aniline violet must also be considered as an aniline base.

Two artificial bases, the amid bases of ethyl and methyl, which but lately had merely been preserved in chemical collections as interesting and rare substances, are now used instead of ammonia, in Carré's ice apparatus, in the artificial production of ice.

The description of the individual members of this extensive series of organic bases or alkaloids could be considerably extended.

As mentioned in the introduction, organic bases were a *terra incognita* to chemists half a century ago. As has probably been gleaned from these remarks, chemists have since diligently laboured to explore this region; but whenever they had succeeded in scaling a height, from which they hoped to obtain a general view of what they had investigated, new and ever greater fields opened to their astonished eyes—fields whose exploration will require the most diligent efforts of chemists for many years.

Just as in the discovery of a new country, the value of which the people realize only when the ploughshare has turned the new soil, and when its treasures have begun to circulate in the great commercial veins and arteries of the world, so it happens with our organic bases, which are generally appreciated only as far as they are useful to commerce, the arts, or medicine.

Let us not forget, however, that as the treasures of the mountains of California and the products of India would never have enriched our country if it had not been for indefatigable travellers, who wandered through unknown countries, impelled by a pure love of knowledge, so we also owe our acquaintance with the organic bases to purely unselfish and scientific investigations, which have taught us that nothing is useless in science—a truth written in conspicuous letters on every page of the book of nature, and which can only fail to be read by the grossest ignorance.

COMMON WILD FLOWERS CONSIDERED IN RELATION TO INSECTS.*

(*Concluded from p.* 348.)

Let us pass on to the genus Primula, which offers a most interesting case of dimorphism. The cowslip and primrose resemble one another in many respects, though the honey they secrete must be very different, for while the cowslip is habitually visited during the day by humble-bees, this is not the case with the primrose, which in Mr. Darwin's opinion is fertilised almost exclusively by moths. This, however, is a digression. If a number of specimens of primroses or of cowslips are examined, we shall find that about half of them have the stigma at the top of the tube and the stamens half way down, while the other half have,

* Abstract of an Address by Sir John Lubbock, Bart., F.R.S., at the Belfast meeting of the British Association.

on the contrary, the stamens at the top of the tube and the stigma half way down. Corresponding differences occur in the polyanthus and auricula, and had long been known to gardeners, and even to schoolchildren (by whom the two kinds of flowers are known as "pin-eyed" and "thrum-eyed"); but it was reserved for the genius and perseverance of Mr. Darwin to explain the significance of this curious phenomenon, and the important part it plays in the economy of the flower. Now that Mr. Darwin has pointed this out it is sufficiently obvious: an insect thrusting its proboscis down a primrose of the long-styled form would dust its proboscis at a part which, when it visited a short-styled flower, would come just opposite the head of the pistil, and could not fail to deposit some of the pollen on the stigma. Conversely, an insect visiting a short-styled plant would dust its proboscis at a part further from the tip, and which, when it subsequently visited a long-styled flower, would again come just opposite to the head of the pistil. Hence we see that by this beautiful arrangement insects will carry the pollen of the long-styled form to the short-styled, and *vice versa*. There are other points in which the two forms differ from one another—for instance, the stigma of the short-styled form is globular and rough, while that of the short-styled is smoother, and somewhat depressed. The pollen of the two forms is also dissimilar, that of the long-styled being considerably smaller than the other—7-7000ths of an inch in diameter, against 10-11-7000ths, or nearly in the proportion of three to two, a difference the importance of which is obvious, for each has to give rise to a tube which penetrates the whole length of the style, from the stigma to the base of the flower; and the tube in the long-styled form must, therefore, be nearly twice as long as in the other. Mr. Darwin has shown that much more seed is set if pollen from one form is placed on the pistil of the other than if the flower is fertilized by pollen of the same form, even if taken from a different plant. Nay, what is most remarkable, such unions in Primula are more sterile than crosses between distinct, though nearly allied, species of plants have in some cases been found to be. The majority of the species of the genus Primula appear to be dimorphic, but not all.

Let us now consider the manner in which the bees are adapted to the flowers. Although we may, in one respect, say that the general organization of the insect is modified with reference to these relations, still the parts which have been the most profoundly modified are the mouth and the legs. If we are asked why we assume that in this case the mouth part and legs have been modified, the answer is that they depart greatly from the type found in allied insects, and that between this type and these modified examples various gradations are to be found. The mouth of an insect is composed of:—1, an upper lip; 2, an under lip; 3, a pair of anterior jaws or mandibles; and 4, a pair of posterior jaws or maxillæ. These two pair of jaws work laterally, that is to say, from side to side, and not, as in man and other mammalia, from above to below. The lower lip and maxillæ are each provided with a pair of feelers, or palpi. In the different groups of insects these organs present, however, almost infinite variations. There are several flowers which are inaccessible to hive bees and to Bombus terristris, which has a shorter proboscis than some of the other species belonging to that genus. Hermann Müller mentions, for instance, that he has seen Bombus terristris endeavouring in vain to suck the flowers of the oxlip (*Primula elatior*). Having satisfied themselves that they were unable to do so, but not till then, they proceeded to cut a hole in the base of the tube, and thus arrived at the honey. This seems to show, he observes, that they act upon the results of experience, and not by what is called mere instinct. Indeed, any one who has watched bees in greenhouses will see that they are neither confined by original instinct to special flowers, nor do they visit all flowers indifferently. Müller mentions several cases in which he has seen honeyless flowers visited by insects; *Genista tinctoria*, for instance, is frequently visited by insects in search of honey, although it does not contain any. Certain insects, on the other hand, confine themselves to particular flowers.

It would also appear that individual bees differ somewhat in their mode of treating flowers. Some humble-bees suck the honey of the French bean and the scarlet runner in the legitimate manner, while others cut a hole in the tube, and thus reach it surreptitiously; and Dr. W. Ogle has observed that when he followed any particular bee she always proceeded in the same manner; some always entering by the mouth, others always cutting a hole. He particularly mentions that this was the case with bees of the same species, and infers, therefore, that they differ from one another in their degrees of intelligence, and his observations—though, of course, not conclusive—are interesting and suggestive. If, again, we examine the hind legs of bees we shall find similar gradations. In Prosopis they do not differ materially from those of genera which supply their young with animal food. Portions of the leg, indeed, bear stiff hairs, the original use of which probably was to clean these burrowing insects from particles of sand and earth, but which in Prosopis assist also in the collection of pollen. In some bees the pollen is collected on the body; and here also we find a remarkable gradation from Prosopis, which has only minute and simple hairs, like a wasp; through Specodes and Nomada, in which the longer hairs are still few, and generally simple, though some few are feathered, to Andrena and Halictus, where the hairs are much more developed; a change which is more marked in Sarapoda, Colletes, and Megachill; still more so in Osmia and Anthophore, until we come to the humble-bees, in which the whole body is covered with long, feathered hairs.

One other peculiarity of flowers is explained if we take this view of the relations of insects to flowers. Many flowers close their petals during rain, which is obviously an advantage, since it prevents the honey and pollen from being spoilt or washed away. Everybody, however, has observed that even in fine weather certain flowers close at particular hours. This habit of going to sleep is surely very curious. Why should flowers do so? In animals we can understand it; they are tired and require rest. But why should flowers sleep? Why should some flowers do so, and not others? Moreover, different flowers keep different hours. The daisy opens at sunrise and closes at sunset, whence its name "day's eye." The dandelion (*Leontodon taraxacum*) opens at seven and closes at five; *Arenaria rubra* is open from nine to three; *Nymphæa alba* from about seven to four; the common mouse-ear hawkweed (*Hieracium pilosella*) is said to wake at eight and go to sleep at two; the scarlet pimpernel (*Anagallis arvensis*) to wake at seven and close soon after two; while *Tragopogon pratensis* opens at four in the morning, and closes just before twelve, whence its English name, "John go to bed at noon." Farmers' boys in some parts are said to regulate their dinner-time by it. Other flowers, on the contrary, open in the evening.

Now, it is obvious that flowers which are fertilized by night-flying insects would derive no advantage from being open by day; and, on the other hand, that those which are fertilized by bees would gain nothing by being open at night. Nay, it would be a distinct disadvantage, because it would render them liable to be robbed of their honey and pollen by insects which are not capable of fertilizing them. It is probable, then, that the closing of flowers has reference to the habits of insects, and it may be observed also in support of this that wind-fertilized flowers never sleep; and that some of those flowers which attract insects by smell emit their scent at particular hours: thus, *Hesperis matronalis* and *Lychnis vespertina* give forth their odours in the evening, and *Orchis bifolia* is particularly sweet at night. Although flowers present us with all these beautiful and complex contrivances, whereby the transfer of pollen from flower to flower is provided for and waste is prevented, yet they are imperfect, or at least are not yet perfect, in their adaptations.

It is, of course, possible that these cases may be explained away; nevertheless, as both insects and flowers are continually altering in their structure and in their geographical distribution, we should necessarily expect to find such instances. Animals and plants constantly tend to adapt themselves to their conditions, just as water tends to find its own level. Many small insects obtain access to flowers, and rob them of their contents. *Malva rotundifolia* can be, and often is, sucked by bees from the outside, in which case the flower derives no advantage from the visit of the insect. In *Medicago sativa* also insects can suck the honey without effective fertilization, and the same flower continues to secrete honey after fertilization has taken place, and when apparently it can no longer be of any use. Fritz Müller has observed, that though *Posoqueria fragrans* is exclusively fertilized by night-flying insects, many of the flowers open in the day, and consequently remain sterile.

In couclusion, the lecturer said he had been good-humouredly accused of attacking the little busy bee because he had attempted to show that it does not possess all the high qualities which have been popularly and poetically ascribed to it. But if scientific observations do not altogether support this intellectual eminence which has been ascribed to bees, they have made known to us in the economy of the hive many curious peculiarities which no polt had ever dreamt of, and have shown that bees and other insects have an importance as regards flowers which had been previously unsuspected. To them we owe the beauties of our gardens, the sweetness of our fields. To them flowers are indebted for their scent and colour, nay, their very existence in its present form. Not only have the brilliant colours, the sweet scent, and the honey of flowers been gradually developed by the unconscious selection of insects, but the very arrangement of the colours, the circular bands and radiating lines, the form, size, and position of the petals, the arrangement of the stamens and pistil, are all ordered with reference to the visits of insects, and in such a manner as to ensure the grand object which renders these visits necessary. Thus, then, an attempt has been made to point out some of the relations which exist between insects and our common wild flowers; the entire subject is one, however, which will repay most careful attention, for, as Müller has truly said, there is no single species the whole history of which is yet by any means thoroughly known to us.

THE TRADE IN DRUGS, ETC., WITH TURKEY.

The trade records of the most important Turkish ports, made up to the latest period, give incidentally some information of interest to the readers of this Journal. Beginning with Aleppo, we find that, as regards the imports of drugs into that port, there has been very little change of late. Somewhat strange to say, however, the largest quantities have been received from Russian and French vessels, while the amount received from British ships is very small. The same remark also applies to the imports of cochineal, very little having been received from British ships: those from Egypt conveyed the largest quantity of the article. The imports of olive oil into Aleppo have not increased, neither have the exports. The exports of scammony roots in British vessels amounted to 465 cases for the year, while only two cases were exported in French ships. The exports of scammony extract were 18 cases in British vessels, and two in French, while the only exports of opium from Aleppo were five cases in Turkish vessels. The export of drugs was very inconsiderable. With regard to the imports of drugs into Aleppo, it is stated that this trade in 1872 felt the influence of a local rush to a new line of business, which appeared to be promising, and the market was soon overstocked. Only a sixth part of the quantity then imported was bought during the past year, and the sale of the articles has subsequently been slow and disadvantageous, over a thousand cases from England, France, and Germany, weighing 135,668 lbs., only fetching £1,080, and a good deal remaining unsold. With regard to olive oil, it is stated that the produce of the olive trees in the province of Aleppo is so badly refined that a small quantity of fine oil has been lately imported from France and Italy for the use of European residents, but it is hoped that the refining will be improved. The exports of castor oil seed from Aleppo remain about the same as usual, being chiefly sent to France, Italy, and Germany; but the trade does not appear to be a very profitable one. The price has fallen on account of the successful competition of the castor oil seed imported from Egypt. Scammony roots are exported from Aleppo exclusively to England, where resin is extracted, drawn from them without that adulteration which renders the exportation of the extract drawn on the spot so unsatisfactory to the consignees, and so unprofitable to the consigners. Little scammony, indeed, is now exported, in consequence of its mixture with other substances. The few shipments made have been sent to England. This line of business is reported to be greatly falling off, through the dishonesty and rapacity of those connected with it. The exportation of opium from the province of Aleppo has been tried, but it could not compete with that from Asia Minor, and its exportation will probably not be tried again.

The chief articles of exportation from the district of Rhodes are sponges, olive oil, sesame seed, storax oil, etc., in all to the value of about £245,000 annually. The exports to Great Britain, which may be estimated at about £90,000 a year, consist principally of sponges. It is stated that the sponge fishery has been rather abundant this year, and the prices paid have been from ten to fifteen per cent. higher than those of the previous year. All sponges sent now to England are packed in boxes, containing generally, it is said, the proportion of one pound of sponge to eight or ten pounds of sand. This system was formerly adopted in other markets of Europe, but experience has shown that it was preferable to forward sponges in their genuine state, viz., without sand, and thus avoid the expense of ten or twelve per cent., which arises out of the operation of sending them. The sponge fishery of late has been carried on very actively, and, in view of the quantity of yield, very successfully. The agricultural produce of the Island of Rhodes, with the exception of olives, is scanty. During the last few years a great number of olive trees have been planted, and they will certainly be, in a few years, a source of considerable wealth to the island. Opium is one of the most valuable productions in Asia Minor. Turkey opium contains a higher percentage of morphia than Indian or Persian, and consequently is in such great favour for medical purposes in Europe and America. In former years the crop of Asia Minor annually averaged from 2,000 to 3,000 baskets or cases of 150 lbs. each. A large quantity was consumed in England; America took a very small portion. The Dutch East India Company, also, for many years, have purchased a considerable quantity to send to the islands of Java, Batavia, and Sumatra. Of late years the consumption has largely increased, especially for North and South America and the West Indies. The crop now averages from 4,000 to 6,000 baskets or cases, and of this quantity the United States require about 2,000 cases. The price has much increased, averaging lately £1 per lb.; fifteen years ago, it averaged 15*s.* per lb. Owing to the late high prices, some persons at Smyrna have recently adulterated the pure drug by mixing it with spurious matter, but, as the fraud has been discovered, purchasers have been very careful from whom they obtain the drug.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 14, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W Envelopes indorsed "Pharm. Journ."*

EARLIER CLOSING.

THE well-worn topic of earlier closing is the subject of another letter which appears in our correspondence columns this week. Having so recently and so often advocated this movement, we should have felt disposed just now to content ourselves with an acknowledgment of the receipt of this letter had it not evidenced that the writer possesses a clearer perception than many of his fellow-assistants of the position they ought to take in the matter. Hitherto most of the complaining has come from one side, and all the performance from the other. There can be no doubt that the majority of employers crave for shorter hours of labour as much as their assistants do, and in illustration of this we may refer to the remarks of Mr. C. B. BELL in his recent address to the Hull Chemists' Association (see p. 392). But the greatest stumbling-block in the way of earlier closing among pharmacists has been the want of unanimity. We think, however, their hands may be considerably strengthened in exercising a gentle pressure upon the recalcitrant minority, by assistants taking up definite ground, and causing the question of hours of labour to enter into the terms of any fresh engagement. Such terms as those laid down in our correspondent's letter—namely, limitation of active duty to twelve hours daily—seem almost to err by not asking enough, and yet we have reason to believe that in many cases they would be a real boon.

On the whole, there has grown up during recent years a much more healthy tone of feeling amongst pharmacists as to the number of hours during which they are to be at the call of the public. It is true, as our correspondent says, that in some cases the movement has utterly failed. But there is a considerable residuum, scattered through the provinces, who now reap the benefit of earlier closing, and we are gratified to learn that several pharmacists in Bond Street, Piccadilly, Conduit Street, and Oxford Street, in the West End of London, as well as others in the City and elsewhere, are now closing their pharmacies earlier (that is, the window shutters at 7 o'clock, and the door shutters at 8 o'clock), thereby indicating their desire to induce the public to send earlier for their medicines. Provision, of course, must always be made for the dispensing of any medicine that may be required, and in making the necessary arrangements employers are entitled to, and will no doubt receive, the active co-operation of their assistants.

PHARMACEUTICAL INSTRUCTION IN FRANCE.

THE report presented to the National Assembly of France on the creation of new faculties of medicine and pharmacy has just been issued, and a very interesting report it is. Instruction in these subjects has hitherto been provided by twenty-one preparatory schools scattered over the provincial towns; by the two faculties of Paris and Montpellier, with which are connected superior schools of pharmacy; and by the mixed faculty of medicine and pharmacy founded in 1872 at Nancy, as a substitute for the faculty of medicine and the Superior School of Pharmacy at Strasbourg.

Diplomas of doctor, of sage-femme of the first class, and of pharmacist and herborist of the first class, can be granted only by the faculties and the superio schools—one qualifying body, that is to say, to th twelve million inhabitants; the faculty of Paris alone absorbing nine-tenths of the candidates. This disproportion between the student class and the qualifying bodies has been keenly felt, and a proposal has been submitted to the National Assembly for the creation of new faculties of medicine at Lyons, Bordeaux, Toulouse, Nantes, Lille, and Marseilles. The claims of these cities to form the seats of qualifying faculties were made the subject of a commission of which the report has been recently published; and after a careful estimate of them, those of Toulouse, Nantes, Lille, and Marseilles are disallowed, while those of Lyons and Bordeaux are admitted. At Lyons and Bordeaux, therefore, there will shortly be instituted mixed faculties of medicine and pharmacy, similar to that already in working at Nancy.

The grounds on which the commission has come to this decision are highly interesting, but are too lengthy and too exclusively French in their tenour to be discussed in our columns. Suffice it to say, that the multiplication of qualifying bodies at central points of the country will not only have the salutary effect of diffusing high-class education over a wider area, but it will lessen the inconvenience and expense hitherto felt by the provincial student in having to resort to distant towns to obtain his diploma; and it will have the further happy result of diminishing the pressure under which Paris has hitherto laboured. More than 5,000 pupils now throng the lecture-rooms and wards of the Parisian school, and of these many have to put up with difficulties in the way of observation and research which reduce the instruction from a system available for all to one in which "the surviva of the fittest," or at least the most pushing, is the dominant principle. What holds good of Paris holds good in a minor degree of Montpellier, the pressure on whose teaching apparatus will be relieved by the schools at Lyons and Bordeaux.

One feature of the new system is its extension of the principle inaugurated at Nancy—that of creating a mixed faculty of medicine and pharmacy. Up to a certain point, of course, the instruction of both is common, and the student of the one must inevitably profit by daily intercourse with the student of the other. It is possible that such a system may thus have the effect of promoting a more genial understanding between doctor and pharmacist, as well as of heightening the intellectual standard of their common vocation—the healing art. But it certainly has its disadvantages.

PUBLIC ANALYSTS AND PRIVATE CERTIFICATES.

A DISCUSSION which has recently taken place at a meeting of the City Commission of Sewers presents some interesting points in respect to the granting of certificates by public analysts. The discussion had its origin in the quotation by the *Times* of a paragraph from Messrs. SILLAR and Co.'s Tea Circular, stating that about 150 half-chests of re-dried tea, which had been under water in the Thames, had been publicly sold in Mincing Lane, and that the catalogues of sale declared that the "kiln-dried teas" had been analysed by Dr. W. S. SAUNDERS, the Public Analyst for the City of London, and pronounced by him fit for sale in the market. One of the members of the Commission having called attention to the paragraph, and produced a sample of "tea-dust" which was alleged to have been taken from the parcel so certified by the public analyst, the matter was investigated by the Sanitary Committee, who, after conferring with Dr. SAUNDERS and inspecting a sample of tea which he produced as a portion of that examined by him, reported that it was "serviceable and good," and had not the slightest resemblance to the sample produced before the Court. The Committee also expressed an opinion that the Medical Officer should be very careful in giving certificates in such cases unless the whole bulk was examined, and not merely a sample.

Dr. SAUNDERS, on his part, described to the Court the circumstances under which the certificate was given, saying that, having been requested by Messrs. HAWES and HERTZ, of Mincing Lane, to analyse some tea which had been accidentally wetted with Thames river water, and afterwards carefully re-dried in a kiln, and having ascertained that the firm was of respectable standing, he proceeded to analyse the tea, and found that it was perfectly sound and fit for human food—an opinion in which he was confirmed by Mr. WANKLYN; he therefore certified accordingly.

Had the matter dropped here, the mild reprimand for want of caution suggested by the Committee might have dispensed with further comment. But Dr. SAUNDERS went on to say further that he gave no authority to Messrs. HAWES and HERTZ to make any use of his certificate, and had no knowledge of their having done so until he saw the reference to it in the *Times*. This brought a retort from the brokers, which portrayed in rather coarse lines the consequences of what we believe to be a very objectionable practice. "Having paid a fee of three guineas "for this document," said they, "we naturally felt at "liberty to mention the favourable result of Dr. "SAUNDERS's analysis at the top of our sale catalogue. "Why Dr. SAUNDERS should be surprised at our "having made this use of an analysis which he had "signed, *even adding his official designation, 'Public "Analyst for the City of London,'* we are at a loss to "conceive."

Now, whilst fully admitting the claim of a Public Analyst to such advantages in fame and purse as the reputation of holding a public office may bring him, we entirely deny to him the right of giving a *quasi* official stamp to certificates issued in a private capacity, by attaching to them any designation or description suggestive of their being issued from a public office. The public are not always apt to discriminate between things that differ, and although nothing might be further from the intention of the analyst than to mislead by appending his title to his signature, it is evident that such an association would very often enter largely into the calculations of the person paying for the certificate, who would consider it a portion of the equivalent for his purchase-money.

MUNICIPAL HONOURS TO PHARMACISTS.

THE list of gentlemen who have this year been elected to municipal honours includes the names of several connected with pharmacy. Amongst them we have noticed those of Mr. SAMUEL RALPH ATKINS, Pharmaceutical Chemist and Local Secretary, elected Mayor of Salisbury; Mr. CHARLES TUCKER, Pharmaceutical Chemist and Local Secretary, re-elected Mayor of Bridport; Mr. JOHN CHING, Chemist and Druggist, elected Mayor of Launceston; Mr. Alderman W. MALTBY, Chemist and Druggist, elected Mayor of Lincoln; Mr. G. PORRETT, Chemist and Druggist, elected Mayor of Scarborough; and Mr. WILLIAM MOUNT, Pharmaceutical Chemist, Canterbury, a Town Councillor. In Glasgow, Mr. JAMES HAMILTON has been elected a Commissioner of the Kinning Park Burgh, by a large majority.

THE INDIA MUSEUM.

DR. BIRDWOOD, whose name will be familiar to our readers in connection with his valuable memoir on the Genus Boswellia, has been appointed by Lord SALISBURY Assistant Reporter on the Products of India and Curator of the India Museum. Dr. BIRDWOOD was for many years Professor of Botany in the Grant Medical College, Bombay. Mr. MOORE, Dr. COOKE, and Lieutenant BOYLE have received appointments as Assistant Curators in the Museum.

THE ROYAL SOCIETY MEDALS.

THE Copley Medal for the present year has been awarded by the Council of the Royal Society to Professor LOUIS PASTEUR, for his researches on Fermentation and on Pébrine. The Rumford Medal has been awarded to Mr. J. NORMAN LOCKYER, F.R.S., for his spectroscopic researches. One Royal Medal has been awarded to Professor WILLIAM CRAWFORD WILLIAMSON, F.R.S., for his contributions to zoology and palæontology, and another to Mr. HENRY CLIFTON SORBY, F.R.S., for his researches on slaty cleavage and on the minute structure of minerals and rocks, for the construction of the microspectroscope, and for his researches on colouring matters.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, October 20, a lecture was delivered before the members of the above Association by F. T. Mott, Esq., F.R.G.S., on "Cryptogamic Botany." There were a large number of the members of the society present. The lecture was of an unusually interesting and instructive character, and was illustrated by some beautifully-executed diagrams. In introducing the subject of the lecture, Mr. Mott said that whether the study of the cryptogamic orders of plants was the first or the last which the student of botany undertook depended in a great measure on the system which was pursued, some botanists beginning with the lower orders of plants, and gradually ascending to the higher, while others began with the higher, and gradually descended to the lower. There were advantages connected with either method, but, perhaps, it was best for the student to obtain a knowledge of the principles of botany by studying those plants in which the organs were plainly developed, rather than those which, from the small size and indistinctness of their various parts, required much closer investigation. The lecturer went on to describe that the whole vegetable kingdom was divided into two great classes, the Phamerogamia, or flowering plants, and Cryptogamia, or flowerless plants, and said that in all probability there were upwards of 200,000 species of plants in these two classes: of these about two-thirds belonged to the class of Cryptogamia, which class was subdivided into ferns, mosses, lichens, and fungi. Mr. Mott then described the distinctive characteristics of these classes, and concluded by showing how these lower orders of plants play their part in the economy of nature, forming by their death and decay soil on which larger and more imposing plants might grow. He urged all his hearers to study some of the subjects he had brought before them, so that the lecture they had heard might prove the germ from which should spring a tree of knowledge. At the conclusion of the lecture, a hearty vote of thanks to Mr. Mott for his services brought the meeting to a close.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second meeting of the session of this Society was held in Anderson's University, on Wednesday, October 28. There was a very large attendance of members, and the President, Mr. Currie, occupied the chair. The Secretary of the Assistants' Section (Mr. Foster) placed several volumes on the table which had been presented to the Society for the library, and proposed a hearty vote of thanks to the donor, which was seconded by Mr. Murdoch, and agreed to unanimously. Mr. Fairlie (Secretary) then announced the receipt of several donations in money, and proposed the election of several new members, which was also agreed to. The other preliminary business having been gone through, it was agreed that the annual festival should this session take the form of a supper and ball.

The Chairman afterwards introduced Mr. William Gilmour, Pharmaceutical Chemist, of Edinburgh (President of the North British Branch Pharmaceutical Society), who delivered an admirable lecture on "Chromatic Phenomena of Crystallization." The lecture was rendered most interesting and instructive by a large number of diagrams and illustrations, shown by the aid of the oxyhydrogen light. Mr. Gilmour was frequently applauded in the course of his lecture, and at the close was awarded a hearty vote of thanks.

Some arrangements were then made for the Tutorial and Practical Pharmaceutical Chemistry Classes. The meeting having been prolonged to a late hour, some other matters of business were postponed.

HULL CHEMISTS' ASSOCIATION.

The Committee of the above Association has arranged that a sixth winter course of twenty lectures, comprising elementary chemistry, materia medica, pharmacy, etc., shall be delivered by Mr. H. J. Parson, in the Society's room, at the Church Institute, Albion-street, on Thurday evenings, at 8.15. Fee for the course, £1 1s., due in advance. The course of instruction will have special reference to the requirements of the Minor examination of the Pharmaceutical Society, which it is now incumbent on all chemists and druggists to pass before commencing or taking charge of a business. Each lecture will be fully illustrated by experiments. At the close of the session it is intended to offer four prizes for competition, viz., Senior and Junior, materia medica and pharmacy; and Senior and Junior, chemistry.

Intending students are requested to send in their names as early as convenient to the Honorary Secretary, Mr. Charles B. Bell.

The commencement of the session was held on Tuesday, October 29, when the Honorary Secretary, Mr. Chas. B. Bell, delivered the following.

Address.

"It is a pleasant custom, and one which is, or ought to be, productive of kindly relations between the students of this and similar institutions, and those under whose direction they are to pursue their course of instruction; that they should meet face to face at the beginning of each session, on the broad ground of a common fellowship, dictated by a common interest. Were any other relation than this implied, I could not have appeared before you this evening in the character of mentor; but yielding to no man in affectionate regard to my younger brethren entering a laborious and ill-paid trade (or, as some designate it, a profession), I could not lightly decline to accept the duty laid upon me by my colleagues, though I might secretly doubt the fitness of the selection.

"If I have any claim upon your attention beyond that which an abiding sympathy confers, I must lay it to the fact that I have endeavoured, ever since the Society was established, to advance the cause of provincial pharmaceutical education, and I sincerely hope that my endeavours have not been in vain. I hope all of you will embrace the study of pharmacy in its highest sense, and intend setting to work with brave, earnest, and honest hearts. The knowledge you will thus have acquired will last you all your lives, and never evaporate like the temporary makeshift of the 'crammer;' and let me most earnestly implore of you to give 'cram' a very wide berth; but work honestly and earnestly, with the determination of being master of all you have undertaken. Let me for a moment call your attention to the inaugural address recently delivered at Bloomsbury Square by Mr. Giles, and notice what he says about 'cram.' 'I express my deliberate conviction that a compulsory curriculum must sooner or later be adopted, and the sooner the better.' And I would advise my young friends to carefully read and digest the earnest and thoughtful expressions therein contained.

"Above all, be true each one to himself in this respect, that he feels and acts as if he knew that it is necessary to keep up the stock of knowledge already gained by the maintenance, more or less, of habits of investigation and study; for at the present time it is impossible for anyone to take his true position as an educated pharmacist unless he diligently keeps himself well posted in all that pertains to chemistry. I know that in many cases the opportunities for self-improvement are few, and the means for cultivating the scientific department of our business so meagre, that it is almost impossible to gain more than a little smattering of it.

"I cannot, therefore, impress too strongly upon all of you the great importance of a just appreciation of the value of time; every person is apt to waste or mis-spend time, and we know, if once lost, it can never be regained;

we can measure its flight, but cannot for a moment arrest its onward progress.

"Much has been said and written, and a very strong feeling exists in the youthful mind, in regard to a subject which I will just mention—viz., early closing. I have always been, and still am, an advocate for this, where it can be accomplished. There is no denying the fact that late hours in our business are in many instances the result of bad habits, and we know how difficult they are to eradicate. One great cause for this in my opinion is that so many people have been brought into the trade who were not sufficiently educated, and from shortness of capital were of necessity compelled to be in their shops from early morn till near upon midnight. The aspect of many things has changed of late years, and as education increases that evil may be lessened more than it is at the present time. In some towns and districts the general public have become educated to a change in this bad custom, and therefore many dispensing chemists now close at a much earlier hour than formerly, although there may be, and are, many exceptions. Still, I hope that with the chemist and druggist the Iron Age of late hours and slavish attention to business is rapidly passing, and that we are gradually approaching the Golden Age. I would, however, say to all my hearers that there may be particular districts and special reasons for some places of business keeping open till a late hour in the evening; and where, from a calm and dispassionate view of these circumstances, it is found to be a necessity, there should not be the expressions of disappointment, irritation, and vexation which I know are now and then forcibly expressed; but rather let there be an attempt made by constitutional means to bring about, if possible, a better state of things.

"I suppose that all of you are anxiously looking forward to the time when, in after life, you will realize the results of the present teaching and training.

"Everything in this life, if neglected, will naturally retrograde and decline into sterility. God has given us minds, and intrusted them to our care, and if we do not cultivate them, and thereby widen the sphere of thought, we most assuredly neglect a solemn duty, and prove ourselves unworthy of the gift:

"'A little learning is a dangerous thing;
Drink deep, or taste not the Pierian spring;
For shallow draughts intoxicate the brain,
But drinking largely sobers us again.'

"And now, gentlemen, in conclusion, we must approach the more serious part of the subject for which you have entered yourselves, viz., that of preparing yourselves for passing those examinations which are necessary ere you can take the responsible and very important position of a chemist and druggist. You have now placed within easy reach for those who are intended for the trade facilities for instruction and study which twenty years ago were almost, if not utterly, unknown in the provinces; London alone had better facilities. At that period very little time indeed was allowed for study, the time being entirely occupied by work 'from early morn till dewy eve.'

"Let me advise you to take for your motto, 'Labor omnia vincit;' let it be your watchword; and when you have passed through your Minor examination, let me as a friend advise you still to persevere, prosecute your studies with renewed vigour, and rest not satisfied till you pass the Major with honours. The expenses incurred in these examinations I feel certain you will never regret, for when you come to take your position as a pharmaceutical chemist, your learning and intelligence will make you superior to the class of men who now are chemists and druggists. If any of you are so unfortunate as to be unsuccessful in passing, forget not that Englishmen have a character for never knowing when they are beaten, but go up again before the examiners, smiling.

"In Mr. Parson I firmly believe you have a gentleman who is fully qualified for giving you the necessary instruction: the Committee have every confidence in him. Let me therefore beg of you to be attentive and respectful to your lecturer, and assiduous in your studies; leave the pleasures of the world for a time, so that you may be the better able to compete for the prizes which are so liberally offered for competition; use every spare five minutes; you will never know till you try what a large amount of work can be performed in a few odd moments. Do not think because you cannot have a couple of hours at a time that you are debarred from study. 'Where there is a will there is always a way.'"

The Committee earnestly requests members of the trade in Hull to use every effort to induce those in their employ to attend these lectures, and suggests to students the great advantages that will accrue to them by so doing.

CHEMISTS AND DRUGGISTS' SOCIETY OF IRELAND.

The first meeting of this Society for the session 1874-5 was held on Monday evening, the 9th inst., at 44, Molesworth Street. Mr. E. M. Hodgeson, President, in the chair. The attendance was very large. In opening the proceedings the President said the first business of the meeting was the election of office bearers for the ensuing year, which was then proceeded with. The President, Vice-President, Secretary, and Treasurer were re-elected unanimously, and each of whom in suitable words acknowledged the compliment. The meeting then proceeded to elect by ballot the committee, when the following gentlemen were declared elected:—Messrs. J. T. Holmes, Robert Simpson, Stanley Oldham, W. Ledger Erson, John O'Brien, and Wm. Allen. The following gentlemen were admitted to membership:—Mr. R. Watson, Mr. Thos. Gillespie, Banbridge; Mr. English, Cahirciveen; Mr. M. J. O'Sullivan, Kingstown. The President then proceeded to state that the most important business to be promoted was the formation of classes, a step he strongly urged in view of pending legislation. A long discussion ensued, and eventually it was decided that classes be at once formed. Professor Tichborne has undertaken the classes in chemistry and practical pharmacy. It is not yet decided who is to be the professor in botany and materia medica. The fee fixed is extremely moderate, viz., £2 2*s.* for two evenings per week for six months. Several, both employers and assistants, at once joined the classes.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The following scheme of prizes for the session 1874-5 offered for competition among the Associates of the above Association, has been issued by the Council:—

Chemistry.

Inorganic,—

A prize (value one guinea) to the student who passes the best examination in the *Elementary Grade.*

A prize (value one guinea) to the student who passes the best examination in the *Advanced Grade.*

Organic,—

A prize (value one guinea) to the student who passes the best examination in the *Elementary Grade.*

A prize (value one guinea) to the student who passes the best examination in the *Advanced Grade.*

Botany.

Elementary and Systematic,—

A prize (value one guinea) to the student who passes the best examination in the *Elementary Grade.*

A prize (value one guinea) to the student who passes the best examination in the *Advanced Grade.*

The examinations in Chemistry and Botany will be those of the Science and Art Department, ordinarily held in May, and only those students who obtain a *first class* in their respective grades will be eligible for the above prizes.

Hills' Prize Fund.

The Council have determined to apply a portion of this fund in the following manner. They offer three prizes, viz.:—

1st prize . . . Value two and a half guineas.
2nd „ . . . „ one and a half guineas.
3rd „ . . . „ one guinea.

To be competed for at an examination on the Chemistry, Botany, Materia Medica, and Pharmacy of the Pharmacopœia; and on the reading and comprehension of prescriptions.

This examination will be held, under the auspices of the Council, in the month of September of next year, and will be open to all Associates who have not passed the Minor or Modified examination of the Pharmaceutical Society.

The Council hope by this scheme to encourage young men to make diligent use of the opportunities which the ordinary routine of shop duties may be made to afford. Consequently, they intend that the examination shall be a thoroughly practical one, based on the syllabus of the Minor examination, for which it should prove a valuable preparatory training. Intending competitors may procure a copy of the said syllabus, with any further information they may require, on application to the Honorary Secretary.

The Council reserve to themselves the right of withholding either or all of the above prizes in the event of the candidates failing to reach the examiners' standard of proficiency.

The prizes will be presented at the first monthly evening meeting in October, 1875, and will consist of books, apparatus, or instruments, at the option of the successful candidates.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, Nov. 4, 1874.—Professor Odling, President, in the chair. After the ordinary business of the Society had been transacted the following papers were read:—1. "On Methylhexyl Carbinol," by Dr. C. Schorlemmer. 2. "On the Action of Organic Acids and their Anhydrides on the Natural Alkaloids," Part I., by Dr. C. R. A. Wright. 3. "Action of Bromine in the Presence of Water on Bromopyrogallol and Bromopyrocatechin," by Dr. J. Stenhouse. 4. "Action of Baryta on Oil of Cloves," by Professor A. H. Church. 5. "Observations on the Use of Permanganate of Potash in Volumetric Analysis, and on the Estimation of Iron in Iron Ores," by Mr. E. A. Parnell. 6. "Further Researches on Bilirubin and its Compounds," by Dr. J. L. W. Thudicum.

The meeting was finally adjourned until Thursday, 20th November, when the following papers will be read:—1. "Action of Organic Acids and their Anhydrides on the Natural Alkaloids," Part II., by G. H. Beckett and C. R. A. Wright, D.Sc. 2. "On the general Equations of Chemical Reaction," by W. K. Clifford, F.R.S. 3. "On Propionic Coumarin and some of its Derivatives," by W. H. Perkin, F.R.S. 4. "Action of Bromine on Pyrocatechnic Acid, Gallic Acid, and Tannin," by Dr. Stenhouse.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of this Society was held on Wednesday, October 7, under the presidency of M. Regnauld.

A note from M. Stanislas Martin was read, accompanying a specimen of leaves of the *Jacarandi bresiliana*, Persoon. These leaves are employed in Brazil as a stimulant, and are popularly called "caroba."

A letter from M. Clanet, jun., a wax manufacturer, residing at Lavelanet (Ariége), was read, asking for information respecting the blue colour which is developed upon the contact of oleic acid with colophony.

M. Poggiale presented a memoir by M. Gault, of Nancy, upon the preparation of "monobromide of camphor," the use of which compound in medicine he said was extending. [A translation of this memoir has appeared on p. 321 of this Journal.] M. Bourgoin remarked that the expression "monobromide of camphor," employed by M. Gault, is incorrect, and that the substance should be called "monobromated camphor." He added that the first fine crystals were obtained, in France, at any rate, by M. Clin

Action of Solar Light upon Iodide of Potassium.

M. Poggiale also presented a memoir by M. Vidau, Pharmacien-Major in Africa, entitled, "The Action of Solar Light upon Iodide of Potassium." [A translation of this paper at p. 383 of the present number of this Journal.] The author reports that he has found that a ten per cent. solution of iodide of potassium acquires a yellow colour under the influence of sunlight, in consequence of the decomposition of the salt. M. Poggiale, after giving a *résumé* of the paper, said that the result would appear to have an important bearing upon the estimation of ozone by means of paper saturated with iodide of potassium and starch.

M. Buignet asked whether the iodide of potassium used in the experiment was chemically neutral, or whether, like most commercial iodide of potassium, it contained more or less carbonate of potassium, as the presence of the foreign salt might affect the stability of the iodide.

M. Méhu thought the coloration might in a certain measure be attributed to the action of chloride of lime remaining from the bleaching process in the cotton used for filtering.

M. Poggiale said this could not be the case, as several of the experiments were made without the use of cotton.

M. Guichard referred to former experiments in which paper saturated with iodide of potassium and starch, placed in a tube and exposed to the sun, acquired a blue colour.

M. Poggiale said that in several of M. Vidau's experiments the iodide of potassium was not mixed with starch mucilage.

M. Latour asked whether the author had made any experiments on solutions sheltered from contact with air, for he had himself noticed, while investigating the conditions of the transformation of nitrates into nitrites, in an acidulated solution containing starch mucilage and iodide of potassium, an indication that the presence of air was indispensable to the production of the characteristic blue colouring of the starch. He would also ask whether the iodide employed was not alkaline, because when it contained no more than one per cent. of carbonate the salt would become yellow spontaneously, and it required an addition of three per cent. of alkaline salt to keep well.

M. Poggiale thought that the objections raised would not affect the validity of the conclusions of M. Vidau, who had experimented comparatively in sunlight and darkness, and with solutions not containing starch.

M. Bourgoin presented to the Society two products, one liquid, perbromide of acetylene; the other solid, which the author designated the hydride of tetrabromated ethylene. He said that a close investigation had shown that these two bodies are isomeric.

Reaction of Acetic Acid on Oil of Peppermint.

M. Roucher exhibited to the Society a coloured liquid presenting a very marked dichroism, obtained by adding to acetic acid (sp. gr. about 1·070) one-twentieth of its weight of oil of peppermint, and agitating the mixture. After about half an hour a faint blue colour appears, which augments gradually in intensity. In proportion as the colour is dark the dichroism is more marked, the liquid appearing of a pure blue colour by transmitted light, and of a fine cinnabar red colour by reflection. The appearance is similar to that of certain aniline compounds in alcoholic solution. The colour is not stable, but passes gradually to green and then to yellow, under the influence of light. Water throws down a very pale blue precipitate from the acetic liquor, and upon filtration there remains upon the paper a portion of the blue colouring matter, which rapidly turns red, and is decolorized in the air. Potash decolorizes the liquid instantaneously.

In order to ascertain whether this reaction was due to the solid or crystallizable portion (menthol) of oil of peppermint, or to the liquid hydrocarbon associated with it, the author dissolved some menthol in acetic acid, but no coloration was produced. Neither oil of turpentine, camphor, nor oil of citron gives with acetic acid a reaction similar to that observed with oil of peppermint.

M. Méhu read a note by M. Patrouillard upon a specimen of white ginger, adulterated with a grey ginger of less value, whitened with starch and carbonate of lime. [Mr. Garside recently called attention to this practice in this Journal, vol. iv., p. 831.]

The President inquired of M. Méhu, the delegate from the Society to the late International Congress at St. Petersburg, whether he was prepared to present his report. M. Méhu replied, that not having yet received some necessary documents, he wished to defer his report until the November meeting.

SOCIETY OF ARTS.

Carbon and certain Compounds of Carbon.*

BY PROFESSOR BARFF.

(*Continued from page* 356.)

Lectures II. and III.

Carbon has the power of combining very readily with oxygen gas. It will combine with it directly, and also indirectly. It is advisable to use this term indirectly, because, only under very peculiar circumstances, hydrogen combines directly with carbon. Carbon combines directly with oxygen, sometimes at the ordinary temperature of the air, and sometimes above the ordinary temperature of the air.

Although it is doubtful whether carbon has ever been vaporized, as soon as carbon comes in contact with oxygen, under suitable conditions, it forms one of two transparent and colourless gases.

If some leaves or sawdust be put into a bottle, and the bottle stoppered up and kept for a time, that bottle will become filled with carbonic acid, whereas it was first filled with air, showing that carbonic acid is formed by oxidation of the carbon in the substance at the ordinary temperature of this air. The temperature in the tube would not be the same as that outside, because chemical action goes on, and there is a slow burning. Therefore the temperature inside the tube would be greater than the temperature outside. If a stack of hay be put up green the chances are that the haystack will take fire, because its carbon, the hay being moist, will unite with the oxygen in the air, heat will be evolved, and at last the temperature will rise so high that it will set fire to the grass or hay. Here by the oxidation of the carbon there is evolution of heat. For the same reason there is evolution of heat when fuel is lighted in a grate, because the carbon in the fuel, as the carbon in the grass, is oxidized by the oxygen of the air.

Our own bodies have a certain animal heat, below which if the temperature of our bodies fall we die. It is not simply, but in great part, owing to the burning or combustion of the carbon and of the hydrogen of the food which we eat, and the products of combustion in all instances are the same.

Underneath the surface of the earth there is much more carbonic acid than above its surface. Four parts in 10,000 is the proportion in the air in a city, or over the great Atlantic, for the proportion varies very little indeed when the air is taken from different places. But underneath the surface of the earth there is a very large amount of carbonic acid. The influence of this carbonic acid there is very interesting. The mineralogist will see that the consideration of it is very important. The botanist will see that it will, in fact, be to him of far greater importance even than to the mineralogist, for it is a very striking thing, that only four parts in 10,000 of the carbonic acid is the quantity in the air, and yet all vegetation takes its carbon from carbonic acid. But there is a much larger quantity of carbonic acid under the earth, and therefore in the water that impregnates the earth. Now, it is not difficult to understand that there is an accumulation of carbonic acid which goes to support the plant, and to enable the plant to build up its structure, and to afford those products which are useful for the support of animal life. This point is not irrelevant, because it is from this source that we get our fuels, and it is of importance and of great interest to know how it is that plants get the material which builds up their structures, and where they get it from.

Carbon and oxygen unite together directly at high temperatures or at low temperatures. In the presence of moisture, carbonic acid gas is the product in almost all cases, because the air is in excess of the carbon acted upon at the time. But another product of oxidation is formed, in which the carbon is in excess of the oxygen. By oxidizing common black lead—plumbago—by means of chlorate of potash and nitric acid, a substance is formed which has properties different from the graphite from which it was formed. This substance was discovered by Sir Benjamin Brodie. From it may be got graphitic acid. It contains oxygen, hydrogen, and carbon. If it be heated it will swell, and if thrown into a flame it will readily burn. Now, the graphite will not burn, so that the graphite has been converted into a form of ordinary charcoal. Let us now connect this with the diamond. If a diamond be heated by the electric current in a vessel from which air has been excluded, first of all it increases in size, and instead of being transparent it becomes opaque; if, at this stage, the specific gravity be taken it will be found that it is much less than the specific gravity of the diamond. Continue heating the diamond, and it turns out a black mass, which is identical with graphite.

Another physical property of this carbonic acid gas is of considerable importance. It can be condensed to a liquid, but under a considerable pressure. This gas extinguishes a light; substances will not burn in it, neither will animals live in it.

Carbonic acid gas has been used as the material in the fire-extinguisher. Carbonic acid gas under pressure is used there. If carbonic acid gas were condensed to a liquid, as a liquid it would occupy a much less space than the gas occupies, so that a very large quantity of carbonic acid gas could be condensed into the liquid state and held in a small vessel. At all fire-escape houses bottles containing this liquid carbonic acid gas should be kept. Of course, they must be of iron, and strong enough to bear a heavy pressure, for the pressure is about 40 times 15lb. to the square inch. In order that the gas might escape readily when thrown into the burning building, these vessels should be made of a cylindrical form, drilled with holes, and those holes filled in with a fusible metal. Then directly the apparatus was thrown into the fire the fusible metal would melt, and the liquid carbonic acid would escape and become gaseous, and of course its volume would increase far beyond the volume it had while condensed; and probably in some of those unmanageable fires, where human beings are not in the burning houses, these vessels thrown into the fire would extinguish the fire almost immediately. The experiment has never been tried in

* Abstract of a course of Cantor Lectures, delivered before the Society of Arts.

this form, but it is one in which it is perfectly reasonable to expect would produce the result.

If a small piece of potassium be heated in a tube in a current of dry carbonic acid gas, the potassium will catch fire and burn, for the potassium acts violently upon the carbonic acid gas, takes away the oxygen from it, and causes a deposition of carbon.

If carbonic acid gas be passed over charcoal heated to redness in an iron tube, it will take up some more carbon, and we get CO and CO. When carbonic acid has taken up this extra weight of carbon, it has lost many of the properties which it possessed as carbonic acid. As carbonic acid it would not burn, but when the carbonic acid takes up these 12 parts by weight more carbon, and becomes carbonic oxide gas, then we have a gas which will burn with a pale blue flame. Suppose CO_2, 44 parts by weight of carbonic acid gas, occupies a definite volume, and suppose CO occupies a volume equal to it, then it is quite manifest that twice CO will be double the original volume, and the consequence is that when CO_2, 44 parts by weight of carbonic acid gas, are passed over carbon, they take up 12 parts by weight of carbon, and form double the volume of carbonic oxide gas. This is a thing also of importance to be remembered.

In what respect does carbonic acid differ from carbonic oxide? It differs in density, for carbonic acid is 22 times as heavy as hydrogen. Carbonic oxide is 14 times as heavy as hydrogen, therefore it differs in density. If 14 times as heavy as hydrogen, it is a little lighter than atmospheric air; if, then, it is formed in any process that goes on in fireplaces, the tendency of carbonic oxide to rush up the chimney will be greater than that of carbonic acid.

Thoroughly to understand how to be able to economize heat, it is necessary to consider the action which goes on in the burning of an ordinary fire, or the burning of an ordinary gas flame. When a fire is lighted a draught is created. The paper is lighted first, because it burns at a lower temperature than wood. The wood is lighted next, because it burns more easily than coal; it is so because the carbon in these are in such a condition that they will more readily unite with the oxygen of the air at the temperature to which they are exposed. The heat evolved by the burning of the paper and the wood in a well-constructed chimney causes a draught. The air gets rarified, and the cold air rushes in to take its place. If air is in excess when it comes in contact with red-hot coal or red-hot wood or paper, the gas formed will be that which contains the largest amount of oxygen. That is to say, carbonic acid will be formed. Now, as the coal gets hot, this carbonic acid gas passes through the heated coal, and takes up twelve parts by weight more carbon. It becomes then carbonic oxide gas, and the carbonic oxide gas comes up to the top of the fire to the upper part of it, and if it is hot enough it unites with the oxygen of the air and forms carbonic acid gas again. On a clear winter's night, when the fire has burnt to a bright glow, a pale blue flame flickers over its surface: that blue flame is caused by the combustion of the carbonic oxide into carbonic acid. The same thing takes place in a gas flame, and will be considered in treating on illuminating substances. What is necessary to notice now is this, that in order that this carbonic oxide gas may be burnt it must be heated. See what happens, then, if too much coal be put upon the fire. The carbonic oxide is formed by the carbonic acid passing over red-hot coal beneath; but the coal on the top of the fire is not hot, and the gas being light, lighter than the air, the tendency is to go up the chimney, and so a large amount of the heating power of the coal is lost. An enormous amount of the heating power of coal is lost in this way, and probably with $\frac{1}{2}$, or $\frac{1}{3}$, or $\frac{1}{4}$ of the quantity of coal we now daily use, we might be able effectually to produce all the benefits now produced by this enormous consumption. This is a scientific reason why fires should not be built up with a large quantity of coal.

Carbonic acid gas contains exactly the same volume of oxygen that the carbonic acid itself measures; whilst carbonic oxide gas contains only half the measure of oxygen which the carbonic oxide itself measures. These are very important facts, when we consider what takes place in the burning of fires. For example, carbonic acid gas is formed in the bottom of the fire; while it passes through the fire the carbonic acid becomes converted into carbonic oxide. Here the volume is doubled, so that in the middle of the fire there is double the volume of gas formed of carbon and oxygen that there was at the commencement. Then, again, when it burns at the top, the carbonic acid is formed again, and double the volume there was at the bottom, because carbonic oxide is burned into carbonic acid.

Now, suppose we take C to be 12 grammes by weight of carbon, then O_2 will mean 32 grammes by weight of oxygen, and the whole of them together will make 44 grammes by weight of carbonic acid gas. At what is termed the normal temperature and pressure—that is, at a temperature of zero Centigrade, and under a pressure of 30 inches of mercury, or 760 millimetres of mercury—that weight of carbonic acid gas will occupy a definite measure; as nearly as possible it is that of twice 11·2 litres.

The 28 grammes of carbonic oxide, under the same conditions of temperature and pressure, will occupy the same volume, viz., twice 11·2 litres. This is true of all the compound gases.

Marsh gas is represented by CH_4. If we add 12 and 4 together we get 16. If we take 16 grammes of this marsh gas, they will occupy the same measure as 44 grammes of carbonic acid, or 28 grammes of carbonic oxide, under the same conditions of temperature and pressure. Compared with the other gases, these two are the principal gases of coal gas, and they are set free whenever coal burns. They are most important substances themselves to consider in a course of lectures like the present, and the changes they undergo in burning are of immense importance to the understanding of the subject, and to the formation of suitable and useful apparatus for our fires and gas for the illumination and warming of our rooms. Marsh gas is also called carburetted hydrogen, because it contains carbon and hydrogen. The other, olefiant gas, is also called carburetted hydrogen, and we distinguish between the two by calling the marsh gas light carburetted hydrogen, and the olefiant gas heavy carburetted hydrogen. Because, although they occupy exactly the same volume, the one contains 12 parts by weight of carbon, whilst the other contains twice that quantity by weight. This marsh gas has also acquired another name, from its extremely dangerous properties, and from the explosions it gives rise to, producing loss of life, in coal mines. It is known by miners as fire-damp, from an old word *damp*, meaning gas or air. It is produced in marshes by the decomposition of vegetable matter, and all vegetable matter that occurs in marshes contains carbon and hydrogen. When this vegetable matter decomposes, certain other things besides marsh gas are formed; but marsh gas is formed by some of the carbon and some of the hydrogen of the vegetable matter. Marsh gas burns with a pale blue flame, probably showing a slightly yellow tint. The flame is not luminous, very little more so than the flame of hydrogen gas. Marsh gas is always set free when substances containing carbon and hydrogen are decomposed slowly or rapidly. Therefore, when coal is decomposed slowly or rapidly marsh gas is set free. When a quantity of this gas gets into a coal mine an explosion takes place, but there are limits as to the quantity of marsh gas and atmospheric air which will produce an explosion. In order that it may burn perfectly there must be sufficient oxygen to form carbonic acid with its carbon and water and with its hydrogen. The carbon in CH_4, or 16 grammes of marsh gas, will require twice 16 grammes of oxygen, or twice 11·2 litres of that gas for their complete combustion; and 4 grammes of hydrogen H_4 will require the same quantity of oxygen, because H_2 requires O or 16 parts by weight of oxygen to form water with them; therefore H_4 will want 32 parts by weight of oxygen, or twice (11·2) litres for their perfect combustion. Now, the product in the first case will be 44 grammes of carbonic acid, which will measure twice (11·2) litres, and in the second four times (11·2) litres, or 36 grammes of water vapour or gas; this action is represented by equation, as follows:—

$$CH_4 + 2\ O_2 = CO_2 + 2\ (H_2O).$$

But inasmuch as in mines we have not to do with pure oxygen, we want to know how much air must be used to burn marsh gas. Now, inasmuch as in one volume of air there is about ⅕ its volume of oxygen, it is quite clear that five volumes of atmospheric air are required to yield one volume of oxygen, and therefore we shall want ten volumes of atmospheric air to yield two of oxygen, and if we want to burn a volume of marsh gas we must have two volumes of oxygen, or ten of atmospheric air. Therefore, when marsh gas is mixed with ten times its own volume of air it makes the most explosive mixture. If it is mixed with only three times its own volume of atmospheric air it will explode, and if it is united with eighteen times it will not explode, but will go on burning quietly. A knowledge of these facts has made possible the construction of a lamp that can be used in otherwise unworkable mines. The principle of Sir Humphrey Davy's safety lamp is this—the iron wire gauze, which is a good conductor of heat, provided it be perfect (and there are about 800 wires in the square inch), and provided it be not oxidized or broken, will conduct away the heat, and the lamp may be put lighted into an explosive mixture of marsh gas and air, and yet the mixture will not explode. The marsh gas and air that are inside will burn inside, but they will not ignite the mixture that is outside the lamp, simply because the iron wire conducts away the heat, and it does not rise to a sufficiently high temperature to explode the mixture of marsh gas and oxygen, or marsh gas and air, which require a very high temperature for their ignition. Of course when the miner sees the flame burning inside the lamp, he ought to withdraw from the workings, because there may be some imperfection in his lamp, and if there were any, even minute ones, when the mixture is in these proportions, if the temperature be high enough, an explosion will take place.

Olefiant gas consists, as has been already said, of a much larger quantity of carbon; in fact, twice 11·2 litres contains 12 grammes more carbon, and the effect of this increased quantity of carbon is, that it makes the gas give more light, it makes it more luminous. When speaking upon coal gas and its impurities and its purification, it will be shown that olefiant gas, which exists largely in coal gas, and is one of those gases which give it its illuminating properties, is an extremely interesting body. It burns with a very different kind of flame from marsh gas, and deposits black soot upon the white porcelain held in the flame, showing that it contains a very considerable quantity of carbon. This deposit of carbon may be utilized to increase the illuminating power of petroleum oils, hydrocarbon oils, and coal-gas. When olefiant gas is passed through a red-hot porcelain tube it deposits half its carbon, and marsh gas is formed; thus it is represented in symbols—

$$C_2H_4 = C + CH_4.$$

The volume of the marsh gas is the same as that of the olefiant gas, for C_2 and H_4 occupy each 2 volumes; but if the marsh gas be passed through a white hot porcelain tube all its carbon is deposited, and hydrogen passes on thus—

$$CH = C + H_4,$$

but H_4 occupies 4 volumes, and CH_4 only 2 volumes; therefore the hydrogen is double the volume of the olefiant or marsh gas, from which it is obtained. The decomposition of these gases takes place in the burning of an ordinary gas flame, and they take place in the burning of a fire, and a knowledge of this decomposition of the gases and the change of volume in the decomposition is a subject of considerable importance.

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act.

Adulteration of Mustard.

At the Greenwich Police Court, on Tuesday, Mr. H. Parr, grocer, of the Trafalgar Road, Greenwich, appeared to an adjourned summons at the instance of the Greenwich District Board of Works, charging him with selling mustard adulterated with starch. Mr. Spencer attended in support of the summons, and Mr. J. B. Smith, solicitor, of Greenwich, for the defence. The case was originally heard on the 8th of October (see before, p. 316), when a certificate, signed by Mr. G. W. Wigner, the District Medical Officer, was produced, setting forth that the sample of mustard, bought at the defendant's shop and submitted for analysis, contained 30 per cent. of starch. At the time this sample was purchased it was averred that the manager, hearing it was purchased for public analysis, took another packet out of the same drawer, which had been submitted to Dr. Tidy, who certified that no starch was to be found in the sample submitted, and upon this difference of opinion it was agreed on both sides that an independent analysis of a portion of that analysed by the district analyst should be made by Dr. Heisch, of Middlesex Hospital. The certificate of Dr. Heisch was now produced, stating that the analysis proved a great admixture of oatmeal, and more than one-third of starch, a greater adulteration than that certified by the district analyst. In answer to questions, Mr. Wigner said the seed of mustard did not contain starch, only something analogous. As a condiment, mustard containing such an admixture of starch would not be injurious to health, but if used as a drug, such as for making a mustard plaster, it would be ineffective. Mr. Smith, for the defence, said that the mustard was considered as pure, and was sold as received in bulk. Mr. Patterson imposed a fine of 10*s.* and £5 8*s.* costs, the latter including £5 5*s.* fee to Dr. Heisch, which were paid.—*Times.*

Alleged Adulteration of Butter.

At Marlborough Street, Brown Webb and Horatio Webb, 69, Great Titchfield Street, cheesemongers and butter merchants, were on Wednesday summoned before Mr. Newton, at the instance of the authorities of the parish of Marylebone, for selling adulterated butter. Mr. Greenwell, Vestry Clerk of Marylebone, prosecuted; Mr. Straight defended. Dr. John Whitmore, public analyst of Marylebone, received a portion of butter from the Inspector of Nuisances for analysis. He found the constituents were 15 per cent. of water, 4·9 of salt, and 8·5 per cent. of casein. In his opinion the article he received did not properly constitute "butter," which meant the "fat of milk." In his opinion the butter was adulterated with water. In the manufacture of cheap butter, cheese matter, or casein, was ordinarily used. Replying to Mr. Straight, witness said the price of butter charged by West End dealers varied. Best butter was charged 22d. or 2s. He considered that more than 10 per cent. of water in butter constituted adulteration. He had analysed many samples of genuine butter, and had always found less than 10 per cent. of water. He was not aware that the quantity of water varied according to the nature of the feed. A different quality of butter was got from the best feeding counties from that obtained from other feeding counties. In the samples of butter obtained from the defendants there was nothing injurious to health. The microscopic test was a very good test, and was used by the most experienced analysts. He had found not more than 1 per cent. of casein in English fresh butter. Mr. Newton asked Dr. Whitmore if the caseine in the sample had been put in or was left in. Dr. Whitmore said the butter when made was washed, in order to wash out the casein. The more completely it was washed the less casein there would be. Mr. Newton said that after this it appeared the butter had not been sufficiently washed, and therefore the casein was left in. Dr. Whitmore said possibly that was so. Mr. Greenwell would remind the magistrate that Dr. Whitmore stated there was 15 per cent. of water in the butter. Mr. Newton asked if Dr. Whitmore would swear that the water was added. Dr. Whitmore would not, but his impression was that the water must have been added after manufacture on account of the quantity. Mr. Straight said the butter was purchased at 1*s*. 2*d*. and 1*s*. 4*d*. per lb. It could not be expected that everyone was able to buy best butter at 22*d*. and 2*s*. per lb. His instructions were that the butter in question was a fair and wholesome butter, and though yielding water and some amount of casein, it was unadulterated. Mr. Greenwell said he did not impute fraud to the defendants. His argument was that butter containing water and casein was not pure butter. The public who bought butter did not expect to find it mixed with water and cheese matter. Mr. Straight said if all the casein was washed out and all the water squeezed out a higher price must be asked for the butter. How then could butter be brought within the reach of the working public? Mr. Greenwell said the question was a most important one. If ingredients were left in butter after it was supposed to be made pure, the Act would be rendered to some extent nugatory. He contended that not to take out the water and the casein was, in fact, an adulteration. If this were not so, then imposition of a dangerous character, such as in drugs, might be practised with impunity. Mr. Newton said that in such state of things a door would be opened to fraud. Mr. Straight read several decisions of the Judges, and quoted the opinions of analysts of eminence to show that there were differences of opinion as to the amount of water and casein to be found in the best butter. Mr. Newton asked Mr. Greenwell if he was inclined to ask for a case. Mr. Greenwell said no. He would be satisfied with the decision of the Court. Mr. Newton said had the evidence of Dr. Whitmore been one tittle stronger he should have convicted; as it was, he would dismiss the summons, with this advice, that the defendants should continue to conduct their business so as to maintain a high character. Mr. Webb wished to know if he was to understand the magistrate to say he was not to sell butter with more than 10 per cent. of water in it. Mr. Newton would give no opinion on that point; all he said was that he must not sell manufactured butter.—*Times*.

An Infatuation for Laudanum.

On Tuesday, Annie Payne, 19, a strange-looking female, was charged on remand, at the Lambeth Police Court, with stealing from inside the shop No. 6, Bird Street, a small bottle containing one ounce of laudanum, the property of John Middleton, chemist. Prisoner on Monday week went to prosecutor's shop and asked for one ounce of laudanum. He declined at first to serve her, but ultimately put the quantity into a bottle and placed it on the counter. She then asked for another article, and while his back was turned ran out of the shop with the laudanum. She was followed and given into custody. Another chemist, carrying on business in Blackfriars Road, stated that about a fortnight back the prisoner asked for sixpennyworth of laudanum, and he served her. Whilst his back was turned for a moment she ran out of the shop with it. Dr. Charles Corbett Blades, of Kennington Park Road, examined her, and gave his opinion she was an habitual laudanum drinker. She told the doctor that she would sooner have laudanum than her dinner. The prisoner now denied intending to steal the laudanum, and Mr. Chance fully committed her for trial.—*Standard*.

Robbery of Drugs.

At Lambeth, on Wednesday, George Charles Wittey and Benjamin Besford, both 16, were charged with breaking and entering a warehouse in York-street, Walworth, and stealing various articles to the value of £10 10*s*., the property of Messrs. Bush, wholesale druggists. On the 28th ult. the prisoners were seen by a police-constable loitering about. Wittey was carrying a brown paper parcel, and on being stopped and questioned he said it contained "scented hair oil." He threw down the parcel and ran away, but was captured. Several bottles were found on him. The other prisoner, when apprehended, denied all knowledge of Wittey, but he afterwards said he had gone with him to Mr. Bush's premises, York-street, Walworth, made an entry, and taken several articles. On Besford was found a large chisel. Mr. W. Bush, the prosecutor, said he was a manufacturing chemist. He identified the articles produced as his property. He found the premises had been forcibly entered, and an attempt made to open an iron safe. Detective Sergeant Ranger said Besford told him that Wittey asked him to do some work for him at 4 o'clock in the morning; he met him, and they went to Mr. Bush's premises. Wittey returned with a number of articles and asked him to carry them, but he refused. The prosecutor said it was the third time his premises had been broken into and plundered. Wittey reserved his defence, and Besford protested his innocence. Mr. Chance committed both prisoners for trial.

Review.

Pharmacographia: a History of the Principal Drugs of Vegetable Origin met with in Great Britain and British India. By Friedrich A. Flückiger, Phil.Dr., Professor in the University of Strasburg, and Daniel Hanbury, F.R.S., Fellow of the Linnean and Chemical Societies of London. London: Macmillan and Co. 1874. (8vo, pp. 704.)

We must preface our notice by at once saying that the book before us is one of the highest character, and fully answers the great expectations which had been formed when it was announced. The authors are so eminently distinguished in the special researches connected with the origin, composition, and characters of drugs, and their observations have already in so many cases conspicuously helped forward our knowledge of these substances, that one is prepared to find in the work upon which they have for several years been closely engaged a masterly treatment of the subject, appreciative reference to the writings of others, and much original matter.

Perhaps, in endeavouring to give an account of this treatise—which may be fitly characterized as an Encyclopœdia—we cannot do better than quote the authors' estimate of their book, as given in the preface. They describe it as "a record of personal researches on the principal drugs derived from the vegetable kingdom, together with such results of an important character as have been obtained by the numerous workers on materia medica in Europe and America," and this well describes its character. The book is not a treatise on medical botany or chemistry, on pharmacy or therapeutics, but is a history and description of the vegetable drugs commonly used by pharmacists in this country. The scope does not seem a large one, and, in the hands of writers of less knowledge, perseverance, and literary ability than the authors, the subject would probably prove of but little interest. Treated, however, in the pages of 'Pharmacographia,' each substance is made the centre of a crowd of facts of interest. The history and traditions of ancient or barbarous nations and of our own land are elucidated, and curious points in geography, medicine, and natural science have been culled from a thousand sources. State papers and ancient MSS., Chinese herbals written long before the Chistian era, Spanish accounts of the wonders of the New World, the classical literature of Greece and Rome, the Arabic writings of the Middle Ages, modern scientific papers, trade returns of the colonies, books of travels, floras and herbaria, all give help, and no source of information seems to have been too recondite or too trivial to find an appropriate place.

The 228 substances included in the volume are arranged under the Natural Orders to which the plants that have been ascertained or are suspected to yield them respectively belong. The Orders follow the sequence usually adopted in England, as represented in the 'Genera Plantarum' of Bentham and Hooker, so far as that comprehensive work has yet gone, and in other publications of the same botanists. Besides the drugs of the British Pharmacopœia a considerable number of those contained in the Pharmacopœia of India are included, as well as several of a chiefly historical interest. We think it would have been desirable to have clearly distinguished the substances which are official in Britain from the others. The materia medica of the United States is not included, not even the plants of the "Primary List" of the United States Pharmacopœia. *Cortex Pruni serotinæ* is one of the very few specially American drugs noticed. Care has been taken in designating the drugs to give an accurate indication of the exact plant-organ of which they consist, a proceeding which, though desirable in itself, has resulted in a few changes of old-established and familiar names. Food-substances, as such, unless also drugs, find no place in the work. Selected synonyms follow the name, and the French and German appellations of the substance. Notes on the origin of some of the names are not infrequently given; Castor Oil takes its name from a strange confusion of *Ricinus* with *Agnus Castus* in Jamaica, and Matico is said to be so called after a Spanish soldier who accidentally discovered its styptic properties.

Under the head *Botanical Origin* much valuable information is given, usually in a few lines. From the known acquirements of one of the authors in this department of botany the determinations here given possess exceptional weight. It will therefore be well to allude to some of importance. In accordance with the views of Miquel and Baillon, the Japanese *Illicium religiosum*, Sieb. is not considered distinct from the Chinese tree (*I. anisatum*, Lour.), yielding star-anise fruits. The sources of Calumba, *Jateorhiza palmata*, Miers (*J. Miersii*, Oliv.), and *J. Calumba*, Miers, are no doubt wisely combined (under the name *J. palmata*). The origin of the drug which has so long done duty for Pareira brava in the shops, and was regarded as derived from *Cissampelos Pareira*, L., remains still unknown. True Pareira brava, as conclusively shown by Mr. Hanbury in this Journal recently, is the woody root of *Chondrodendron** *tomentosum*, Ruiz & Pav., whilst *Cissampelos Pareira* seems to have never been an object of export to Europe. The source of Savanilla rhatany is determined to be *Krameria tomentosa*, St. Hil., and the Lignum Vitæ of the Bahamas is furnished by *Guaiacum sanctum*, L. *Boswellia Frereana*, lately described and figured by Birdwood as one of the olibanum-producing trees of the Somali country, is here considered to be the source of the Oriental or African elemi of the old writers; the exudation differs essentially from olibanum in containing no gum. The source of the elemi of the British Pharmacopœia remains still uncertain; it is the produce of a tree growing in the Philippines, but the statements referring to the plant on pp. 130, 131 of the book under notice seem to be somewhat contradictory. Eight species of *Astragalus* are enumerated as known to yield gum tragacanth to a large extent in Asia Minor, Persia, and Luristan, and the product is known to be obtained in less quantity from others. The authors are not inclined to restore Linnæus' genus *Toluifera* for *Myroxylon*, on the ground of the inconvenience of the change, a plea of no great weight in this instance where so few species are involved; neither can they follow Baillon in combining *M. Toluifera* and *M. Pereiræ* into a single species; indeed, they give distinguishing characters derived from the pod and the inflorescence. A list of four species of *Copaifera* is given as furnishing copaiba balsam; *C. multijuga* is discarded, there being no sufficient evidence to show even the genus to which it belongs. *Acacia Verek* has been shown by the celebrated traveller Schweinfurth to be the exclusive source of the best African gum arabic. True catechu is a product of *Acacia Suma*, Kurz, in India, as well as of *A. Catechu*, Willd.; and Gambier, or pale catechu, of *Uncaria acida*, Roxb., as well as of *U. Gambier*, Roxb. The puzzles of materia medica are still found in the Umbelliferæ; the true origin of Galbanum, Sagapenum, and Opoponax is stated to be still unknown, whilst, in spite of all the study devoted to the two "asafœtida" plants, *Narthex Asa-fœtida*, Falc. and *Scorodosma fœtidum*, Bunge, the authors consider that it is still unproved that either yields the drug, or is certainly the same as Kaempfer's *Asa-fœtida disgunensis*.* A useful table of the species of *Cinchona*, with references to figures, native country, and products, is given at p. 318. The origin of Santonica is shown to be *Artemisia maritima*, var. *α. Stechmanniana*, Besser (*A. Lercheana*, Kar. & Kir.), found near the Don and Lower Volga, and the Kirghiz steppes of Turkistan: *A. Cina*, Willk., does not quite correspond with this. The long pepper of commerce is chiefly obtained from *Piper officinarum*, Cas. DC. (*Chavica officinarum*, Miq.), of Java. *Maranta arundinacea*, L. and *M. indica*, Tuss., both of which yield arrowroot, are combined into a single species; but the species of *Canna* whence Tous-les-Mois starch is extracted, has not been determined. The species of *Smilax* affording the Sarsaparillas of commerce are *S. officinalis*, H.B.K., which yields Jamaica, and *S. medica*, Schl. and Cham., which gives Vera Cruz Sarsaparilla: the sources of the other kinds are doubtful. Grass oils are the products of three Indian species of *Andropogon*; *A. Nardus*, L., affords citronella oil, *A. citratus*, DC., lemon grass oil or oil of verbena, and *A. Schœnanthus*, L. rusa oil, oil of ginger grass or oil of geranium. *A. Calamus-aromaticus*, of Royle, is referred by Gen. Munro to the last species.

The native countries are very carefully determined, a matter often of great difficulty in the case of plants so extensively cultivated as are many of these. Botanical descriptions were not within the scheme of the authors, but we think a more systematic quotation of the books where such can be found and of published figures would have been very useful.

The *history* of the substance follows. It would be rash indeed to attempt any criticism of this portion of the book. In few words, only possible to writers who are complete masters of their subject, the intricate collection of scattered information is reduced into an orderly and interesting narrative, the copious references at the foot of the pages to books, papers, and MSS., many obscure, rare, and difficult of access, in every department of literature, giving us an indication of the immense amount of work which must have been necessary before the short account could have been penned. These references are very full (dates are always given), and show a thoroughness and determination to get to the very fountain-head of information, which is certainly admirable. The articles, for example, on rhubarb, pepper, cinnamon, camphor, and attar of rose, may be cited as showing a wealth of information and knowledge on recondite branches of research, and a power of putting the important facts forward in a terse narrative which is not often met with.

Under the head of *Collection*, *Preparation*, or *Manufacture*, we have information about the mode in which the product is obtained. Most of this is from the accounts of travellers, ancient and modern, and some has not been before published. At p. 450 is an interesting account of

* Mr. Hanbury prefers to spell it *Chondodendron*, as found in Ruiz and Pavon's 'Prodromus'; but it seems probable that the omission of the *r* was an accidental misprint.

* The *Ferula Assafœtida* of Linnæus, not of Hope.

the preparation of English rhubarb near Banbury, where *Rheum Rhaponticum* has been in cultivation since 1777; and at p. 642 Mr. Spruce, the Brazilian traveller, describes the collection of sarsaparilla.

After this comes a full and careful *description* of the drug, pointing out its salient characters and the minute marks of distinction. Great care has evidently been bestowed here, and as scientific descriptions of materia medica they are models. A section on *Microscopic Structure* follows, which is not very full; indeed, as the authors state, and as we are convinced is the case, long descriptions, without figures, of microscopic structure leave but little definite impression upon the mind of the reader.

The *Chemical Composition* is treated more fully, yet with great brevity. The researches of very numerous chemists are shortly alluded to, but scarcely ever detailed. All the important constituents are mentioned, and references are given to the original sources of information in many cases, though not in all; the date, however, is usually afforded. Descriptions of the chemical processes and products were no part of the authors' plan.

The section on *Commerce* gives trade information, and consists of statistics of the values and quantities imported in recent years into this country, or exported from foreign countries or the colonies, and often similar information with regard to other lands. A brief indication of the medicinal *uses* follows, and concludes the plan upon which each substance is treated. Appended, however, to many is a section headed *Adulteration* or *Substitutes*, in which is given information about other products which are found under the same name in the trade, or are accidentally or intentionally substituted. Here the authors have trusted to actual observation, and have not swollen their book by information taken second-hand. Under some drugs, elemi, kino, manna, camphor, etc., there is much additional matter in this section, including the history and description of products of almost equal interest with the main subject of the article.

Such is the scope and substance of this remarkable book, which, so far as we know, is unlike any other existing, and must be held to fix the period of a distinct advance in the subject to which it is devoted. Doubtless there will be some who regret the omission of certain substances, and of course the list might have been almost indefinitely extended. In nearly the earliest English* work of at all a similar kind, the 'Pharmacologia' of Samuel Dale, the friend and neighbour of the great Ray, printed so long ago as 1693, a list of as many as 519 substances, animal, vegetable, and mineral, commonly on sale by the druggists of London, is given, and a supplement was published in 1705, containing very many more. But what is gained in the way of an extensive list is small compared with the loss of other information, and little indeed is told us by Dale of the substances so fully treated by the authors.

The 'Pharmacographia' is not, and never can be, a text-book; it is essentially a reference-book. Its influence on the progress of our knowledge of the materia medica can therefore never be estimated by the number of its readers. The persons to whom it will be useful at first hand must be few, but to those few it will be indispensable. The trustworthy and authentic matter it contains will, however, in due course, percolate through to the general mass of students, and, embodied in lectures and text-books, become the property of all, and thus the science of Pharmacology will be helped forward in no slight degree.

A word in commendation of the get-up of the volume. Clear and well-arranged type, very few typographical faults, and a neat, handsome binding are good points, and the single copious index a practical convenience not to be underrated.

* The book is written in Latin, in accordance with universal practice at the period.

BOOKS RECEIVED.

TINNITUS AURUM; or, NOISES IN THE EARS. By LAURENCE TURNBULL, M.D., etc. Philadelphia. Lippincott and Co. 1874.

ON DEAF-MUTISM, and the Means of Educating the Deaf and Dumb. By LAURENCE TURNBULL, M.D. Philadelphia. 1874.

Notes and Queries.

AN EXPLOSIVE MIXTURE.—A mixture of chromic acid and glycerine having been recommended in the United States for affections of the mouth, scrofula, etc., Dr. Mascarel takes occasion to warn dispensers that if these substances be rubbed vigorously the result will be an explosion, an accident that may be averted by adding the glycerine drop by drop and rubbing slowly.

MOSQUITO BITES.—Mr. D. De Berdt Hovell states (*Brit. Med. Journ.*, Oct. 31) a mixture of carbolic acid and olive oil, in the proportion of one fluid drachm of the acid to an ounce or an ounce and a half of the oil, applied to mosquito bites, relieves the irritation and promotes the healing; moreover, it will effectually keep off other mosquitoes. He has also found a weak solution of carbolic acid (1 in 100), applied to the face and neck, efficacious in preventing gnat bites.

PHARMACEUTICAL EDUCATION.

Sir,—I have read with considerable pleasure Mr. Giles's inaugural address, and I hardly know which to admire most, his philippic against "cram" or the judicious and carefully considered letter from Mr. Barnard Proctor, in your last number.

The subject of pharmaceutical education is one which in Ireland causes us considerable uneasiness and anxious thought. In fact, outside its general bearing it is a subject of vital importance to the chemist and druggist at present in business in Ireland, who hopes to maintain his position as advanced guard against the inroad of any forthcoming army of pharmaceutical students.

There was a movement made last year to extend the action of the Pharmaceutical Society to this country, and there can be little doubt that had the Council shown a greater desire to promote the "object of the Pharmaceutical Society" (*vide* Charter of Incorporation), the movement would have been received with much more favour.

The attitude of the Society on that occasion was antagonistic to pharmaceutical education. It meant commercial death to the existing chemists and druggists in Ireland, utter sterility as regards the production of students, and stagnation to the development of the art generally. Of all the contending interests at stake it only presented a possible advantage to the Society itself by an extension of its sphere of action.

I sincerely hope the Council will see fit to practically endorse Mr. Giles's condemnation of "cram;" firstly, by the institution of compulsory education. As a public teacher in a medical school where attendance upon lectures is the order of the day, I can bear testimony to the satisfactory way in which it bears fruit. If the said school is not numerically the strongest, it is second to none in turning out the men who are the workers in their profession. Secondly, the Council can do a great deal by the development of the practical examinations which they seem to have adopted. Dependence upon examination papers may facilitate the examination of a large number of students, but will also as certainly play into the hands of the man who works to pass, but not to know.

C. R. C. Tichborne.

40, *Mary Street, Dublin, November* 4, 1874.

[*** Our esteemed correspondent seems to labour under some misconception as to the attitude of the Pharmaceutical Society in relation to the movement he speaks of for extending the action of the Society to Ireland. It is with amazement we note his opinion that the attitude of the Society was antagonistic to education, and that the extension of the Society's sphere of action presented even a possible advantage to the Society. Of course we do not affect to dispute the proposition that there should be in Ireland the same kind of provision for ensuring the qualification of all who practise pharmacy, nor do we attempt to deny that the Pharmaceutical Society would view with entire sympathy the adoption in Ireland of any measures calculated to bring about so desirable an object. It is with this feeling we believe that the movement lately instituted in Ireland has been regarded by the Council, and if that movement has, so far, miscarried, this result must be attributed, not to the antagonism of the Pharmaceutical Society, but to the bewildering multiplicity of the projects by which the good of Irish Pharmacy was to be provided for, and the determined energy with which the projectors seemed to seek the fate of certain cats of their own country.—Ed. Ph. Journ.]

Earlier Closing.

Sir,—Speaking for myself and my fellow-assistants, I think I may say one of the greatest grievances we have to complain of is the long day behind the counter, leaving us so little time for study, and none at all for outdoor recreation, which is so necessary for physical health, unless our studies are neglected.

Many letters have appeared in the Journal, lamenting the state of affairs, but the writers are slow in proposing a remedy. The general impression seems to be that when the pharmacist becomes a better educated man there will be a corresponding improvement in his position. To hang our hopes on that seems very much like setting the cart to draw the horse. It is evident that only the assistants of the present can become the pharmacists of the future, and whilst no opportunities are afforded them of accumulating useful knowledge, it is equally evident that the next race will not be much in advance of the present.

Much has also been written about raising the status of the British pharmacist to a level with that enjoyed by his continental compeer. Great things usually have small beginnings; therefore, I would suggest that he be first raised on a level with his neighbours—I mean the draper, ironmonger, etc. When the latter point is reached, we may with confidence aspire to the former.

The remedy I have to propose is simple, and I believe practicable. 1st. Let every assistant be determined not to take a situation where the time of active duty exceeds twelve hours daily. 2nd. Let him stipulate with his employer that he shall be allowed to study works on pharmacy and the allied sciences during business hours, when he would be otherwise unemployed.

Employers in many towns have attempted to unite in adopting the early (?) closing system, but in most cases have completely failed. Let the assistants unite, and, if necessary, form a society, which would doubtless be successful in bringing about a reformation, and by so doing they would deserve the thanks of their employers, if they did not receive them.

Just a word respecting the Bank holidays. In some towns it is the good fortune of the favoured chemists residing there to close their establishments; in such cases it is usually necessary for the assistant to be indoors half the day, and in some instances hard at work, whilst the better paid assistant at the hatter's opposite is at liberty to go wheresoever he will. Now, what is there to prevent the chemist giving his assistant a half holiday the next day, to compensate for the necessary denial on the first? But if an assistant made such an unusual request he would be considered a most unreasonable man, and more fit for a lunatic asylum than to undertake the responsible duties of a dispenser of medicine.

An Examined Assistant.

Therapeutic Use of Amorphous Phosphorus.

Sir,—In reference to the discussion on the therapeutic uses of the preparations of phosphorus, it may be of interest to some to know that in 1853 the amorphous phosphorus was administered to animals by Dr. R. M. Glover, and his experiments led him to the conclusion that this substance was without either the deleterious or the active physiological properties of ordinary phosphorus. *Vide Lancet*, 1853, p. 34.

I have myself frequently prescribed phosphorus with great advantage, and have been perfectly satisfied with the gelatine capsules of the phosphorated oil, each one of which contains one-thirtieth of a grain of phosphorus.

In many cases of neuralgia, and of nervous exhaustion with sleeplessness, the effect of one capsule three times a day is most successful.

John C. Thorowgood, M.D., F.R.C.P.

61, *Welbeck Street, W., November* 10, 1874.

Sir,—The lateness of the hour at the conclusion of the last evening meeting prevented me from replying to two or three observations elicited in the discussion on my paper on amorphous phosphorus. Professor Redwood asked with regard to the recommendation to prepare phosphorus pills by dissolving phosphorus in suet, and coating pills from it with gelatine, what would become of the suet pills when put into melted gelatine? I answer, provided the solution of gelatine was *not* used hot, and the pills were taken out again and allowed to harden, it would be found that they were coated with a material which would dissolve again very rapidly when taken into the stomach.

Mr. Greenish observed that some time ago a medical man of his acquaintance was in the habit of prescribing amorphous phosphorus, but that he gave it up. Will Mr. Greenish favour me and your readers with the information as to what dose was ordered, how frequently, and for what length of time it was given, also in what form? My object in asking these questions is simply to bring out all the information I can relative to this form of the element, and then leave it to therapeutists to decide whether or not it has value in medicine.

Mr. Mackay instanced one ounce being given to a dog without any injurious result. This, however, was not the best method of eliciting truth. Had the experimentalist who gave one ounce to a dog, and then looked for injurious results, given only a few grains twice or three times a day, for a month, probably the brilliancy and luminosity of his dog's coat would have been such as to cause Ethiop's mineral for ever to sink into obscurity, when compared with the efficacy of amorphous or allotropic phosphorus.

J. E. M.—We believe the name is intended to represent an extract of the herb *Galium Aparine*.

"*Pilulæ.*"—The formula for varnishing pills was given by Mr. Haselden in the *Pharm. Journal* for Dec. 9, 1871, p. 467.

"*Minor.*"—Formulæ for cod-liver oil emulsions were given a few months since in vol. iv., pp. 466 and 581.

"*Alpha.*"—Probably the books used by you in preparing for the Minor examination would suffice for the Major. We believe the purchase of second-hand scientific books is, as a rule, false economy, and frequently leads the student to attribute undue importance to obsolete theories. It is best to obtain the latest editions, and these are seldom found on second-hand bookstalls.

J. J. H.—If you refer to p. 368 of our last number you will perceive that your wish has been anticipated.

D. D. D.—No.

"*One who has passed the Major.*"—(1) We do not think it advisable to revive the discussion by the publication of your letter. (2) The word which puzzles you probably represents a customer's peculiar way of pronouncing "unguentum."

W. Wilson.—We are not aware that magenta crystals would be poisonous unless they contained arsenic.

Communications, Letters, etc., have been received from Messrs. Steele and Marsh, Mr. Rimmington.

THE MICROSCOPICAL USE OF GLYCERINE JELLY.

BY HENRY POCKLINGTON.

Various attempts have been made at different times to devise a "medium" which shall possess the enormous advantage of glycerine as a mounting medium, and also the "setting" properties of such a substance as Canada balsam, and various formulæ for the preparation of such media have been published at different times during the past twenty years. The earliest of these were, I think, published by the late lamented Mr. Deane — whose gelatine medium is peculiarly adapted for certain classes of objects, but is not, to my mind, in any way an efficient substitute for glycerine —and Mr. Farrants, whose "medium" appears to have nearly fallen out of use, having been quite superseded by one form or other of glycerine jelly. The first formula for this with which I became acquainted was that published by Mr. Lawrence, in the *Quarterly Journal of Microscopical Science*, in 1859.* It is a very good formula, as I can testify from personal experience, having objects in my cabinet that were mounted in the medium in 1862, without the use of any cement for securing the cover, and now nearly as good as when first mounted. The formula is this:— "Take any quantity of Nelson's gelatine, and let it soak for two or three hours in cold water; pour off the superfluous water, and heat the soaked gelatine until melted. To each fluid ounce of the gelatine add one drachm of alcohol and mix well, then add a fluid drachm of the white of an egg. Mix well while the gelatine is fluid, but cool. Now boil until the albumen coagulates and the gelatine is quite clear. Filter through fine flannel, and to each fluid ounce of the clarified gelatine add six fluid drachms of Price's pure glycerine, and mix well." Mr. Lawrence also suggests the substitution of a mixture of two parts of glycerine and four parts of camphor water for the glycerine. Two other formulæ, used by myself for some years, differ from the above in omitting the alcohol, and in the quantity of glycerine employed. For dense tissues or objects requiring a somewhat unusually "strong" medium to counteract their elasticity, I use a medium containing about half a drachm less glycerine than that devised by Mr. Lawrence, the alcohol being entirely omitted. The jelly usually used by me for wood sections, and the coarser preparations generally, is made as follows:—I take an ounce of the soaked gelatine before described, using the French clear gelatine in preference to Nelson's—which requires extra care in filtration on account of its "opaque" element—and add to it an equal quantity of the best glycerine, Price's by preference, in which I have dissolved a few grains of arsenic (or added a few drops of carbolic acid solution), filtering and clarifying the whole as before.† A very good jelly for fine tissues is made with double this quantity of glycerine. For very fine tissues, where it is of great importance to secure as little change as possible, a greater proportion of glycerine still may be used, either with or without the addition of gum arabic.

Mounting in glycerine jelly is not without its difficulties. I have had, in "another place," many inquiries on this point, and complaints that in the best of mounts air bubbles appear after the lapse of a short time, and gradually extend, so as to utterly spoil the preparation. These, however, are not air bubbles but vacuoles, and are caused either by the elasticity of the specimen, which when released from the pressure of the mounting clip slightly raises the cover, forming little vacuolor spaces in the gelatine medium, or by the absorption of some of the glycerine from the jelly by the object. This latter is, I think, a very frequent source of trouble, and can be obviated in either of two ways. What these are may best be shown by describing the two methods somewhat in detail.

The first plan is the older plan. The objects are soaked for some time in glycerine until thoroughly permeated with it, and all air bubbles removed. If the tissue be of that class which includes many air spaces, such as sections of herbaceous stems, it will be found desirable to place it in alcohol for several hours before transferring it to glycerine. When the tissue has been in the glycerine sufficiently long, it is removed to a glass slip, and all superfluous glycerine removed. A little melted jelly is dropped upon it, the slide and cover having been previously warmed, and any air bubbles that may appear removed by the point of a needle. The cover is now to be slightly moistened by being breathed upon and carefully lowered into the fluid jelly on the slide, and a little gentle pressure applied until the jelly sets, when all waste jelly should be removed, and any ornamental varnish desired may be applied to the edge of the cover. This method of mounting is specially adapted for very delicate tissues, as it enables us to transfer the tissue gradually from one fluid to another, and so obviate changes in the arrangement of cell contents by endosmose or osmose, such as certainly will occur if a delicate tissue be transferred from a fluid such as water to dense glycerine or glycerine jelly, and it alone is applicable to starches when these are mounted in jelly, and to the spores of certain minute fungi. But it is a very tedious method in the case of wood sections and dense tissues generally. For these I adopt a method I devised originally for mounting these tissues in dammar and balsam, and which was published by me in 1871 or 1872. The section, if of unusually dense tissues, should be placed on the slide in a drop of glycerine, covered with a thin glass held down by a small spring clip,* and boiled for a few seconds over a spirit lamp, great care being taken to allow ebullition to occur for only a fraction of a second at a time. As much of the superfluous glycerine as possible should be removed from under the cover, not moving it if the object be fragile, and the jelly applied in a drop at the edge of the cover opposite to that by which the glycerine is removed. When the jelly has replaced the glycerine the slide is to be carefully heated until the jelly boils under the cover (still held down by the clip), when the slide should be removed from the lamp, the clip slightly raised, to allow bubbles to escape from under the cover, and replaced, and the slide re-heated till the jelly *nearly* boils. The whole is now to be set aside to cool. When the jelly has set the slide may be cleaned and the cover cemented down. This method, carefully applied, is adapted for a much greater range of objects than would be at first supposed, and even

* Carpenter, "The Microscope," 3rd Ed., 775.

† Since this went to press my friend, Mr. James Abbott, has informed me that he follows with advantage a formula published in *Science Gossip*, for March, 1874, by Messrs. Underhill and Allen, in which chloride of barium is substituted for arsenic. I regret not having seen this article before, for it is of great value.

* Spring clips which answer this purpose exceedingly well may be bought of Fields, of Birmingham, W[illegible]pear, of Hull, and other opticians.

such delicate preparations as sections of growing tissues, or embryos of phanerogams, may be treated by it with slight distortion of their outline, and no disarrangement of the tissues. It has the great advantage to busy men of permitting the whole preparation and mounting of wood sections from green wood to be done in a very few minutes, the natural colours of the endochrome being nearly always retained for a considerable time; and, furthermore, objects thus prepared seldom, if ever, become disfigured by the appearance of the so-called air bubbles.*

ALKALOIDAL COMPOUNDS WITH IODINE.†

BY HARRY S. BAUER.

Of the chemical constitution of the majority of the alkaloids little more than their elementary composition is yet known. Berzelius, upon the ground of their evident similarity to ammonia, put forward the theory that they contained ammonia, combined with various atom groups, which in some cases were hydrocarbons, but in most consisted of carbon, hydrogen, and oxygen, and were generally associated with nitrogen. From another point of view it was asserted that one portion of the nitrogen is in closer combination with the oxygen, and it has also been suggested that it exists as cyanogen. Liebig has expressed the opinion that the organic bases are amido-compounds, *i.e.*, ammonia, in which an atom of hydrogen is represented by an organic radical.

According to the latest experiments of A. W. Hofmann and Wurtz, which have made known numerous artificial organic bases, it is put beyond doubt that every alkaloid may be considered as a partially or wholly substituted ammonia (amine, or amidamine).

The alkaloid forming plants belong with few exceptions to the dicotyledonous class. Of the monocotyledons only the colchicum family is known with certainty to produce vegetable alkaloids. Many families of plants are free from alkaloids, as the Labiatæ and Compositæ. Several families contain an alkaloid that is common to others, as berberine, in the Anonaceæ, Berberidaceæ, Menispermaceæ, Papaveraceæ, Rutaceæ, and Ranunculaceæ. Others contain two or three alkaloids, as the Cinchonaceæ and the Solonaceæ.

Nearly all the alkaloids are stable at ordinary temperatures; the greater part are not volatile, and are soluble in water with difficulty. Alcohol dissolves all, and ether many of them; chloroform, benzol, and carbon bisulphide are occasionally also good solvents. Phosphomolybdic acid, nitropicric acid, tannic acid, and metawolframic acid form with nearly all the alkaloids salts that are difficultly soluble in water and acids.

The author considered it would be specially interesting to investigate the action of iodine in solution of iodide of potassium upon the different alkaloids. Serullas, Pelletier, and others had already investigated their iodic salts. The following are the compounds of alkaloids with iodine which are described by the author. Full details of the experiments upon which the formulae are based are given in the original paper.

Compounds of Quinine with Iodine.

Iodoquinine.—$4 (C_{20}H_{24}N_2O_2) 3 I_2$.—The vapour of iodine acting upon quinine colours it superficially yellow. Pelletier stated that by triturating together one part of iodine and two parts of iodine, with the addition of alcohol, at first iodoquinine is formed, and afterwards hydroiodoquinine, in spongy crystals, and that if this latter were removed by hot water the iodoquinine would remain as a saffron-yellow friable mass, softening at 25° C., and melting at 80° C. In one hundred parts he found 69·69 quinine, and 30·31 iodine, from which data Gerhardt constructed the formula—$2 C_{20}H_{24}N_2O_2, I_2$. This statement by Pelletier the author is unable to confirm. He rubbed together the proportions of iodine and quinine stated, then poured the alcohol upon the mass, of which but very little was dissolved. The mass was of a uniform red brown colour; nothing was removed either by hot or cold water. The small portion that was soluble in alcohol was thrown down upon the further dilution of the alcoholic solution with water. After the precipitate had been dried it lost the property of dissolving in alcohol; it was, however, easily soluble in solution of iodide of potassium. The compound had evidently undergone some change, and in order to ascertain whether it had lost either iodine or quinine, the filtrate was tested with delicate tests for iodine, but none was discovered. Upon the addition of caustic soda, however, quinine was immediately precipitated. The substance precipitated from the alcoholic solution was amorphous, and of a deep yellow. Analysis indicated the formula, $4 (C_{20}H_{24}N_2O_2) 3 I_2$. The estimation of the iodine was made by precipitating with nitrate of silver, with which the reaction very readily takes place.

Very accurate results were obtained in estimating the alkaloid (after the removal of the iodine) with iodohydrargyrate of potassium. This reagent was suggested for the qualitative detection of alkaloids by Winkler in 1820, and recommended by Planta-Reichenau in 1846; F. F. Mayer employed it for quantitative analysis. The solution contains 13·456 grams of chloride of mercury, and 49·8 grams of iodide of potassium to the litre. The method is a very delicate one, in many cases excelling even the phosphomolybdic acid test. Distinct evidence is obtained with a solution containing 1 part in 2,500 of morphia, 1 in 2,500 of nicotine, 1 in 7,000 of atropine, 1 in 8,000 of coniine, 1 in 15,000 of strychnine, 1 in 5,000 of narcotine, 1 in 50,000 of brucine, 1 in 50,000 of quinine, 1 in 75,000 of cinchonine, or 1 in 125,000 of quinine.

Iodoquinine.—$4 (C_{20}H_{24}N_2O_2) 5 I$.—The residue which was not dissolved by alcohol in the preparation of the above iodoquinine was of a deep brown colour, and nearly resinous consistence, and contained isolated dark brown acicular crystals. Analysis showed it had the composition $4 (C_{20}H_{24}N_2O_2) 5 I$.

Quinine Hydriodate.—$C_{20}H_{24}N_2O_2,HI$.—Obtained from the acid and the base. It is necessary, however, that no excess of hydriodic acid should be used, otherwise an acid hydriodate of quinine will result.

The hydriodate of quinine crystallizes in slender, brilliant yellow needles, hardly soluble in cold water, readily soluble in alcohol and ether. Winkler also

* In the face of the numerous recipes that have been published for the preparation of jelly, and published methods for mounting in the same, I do not claim priority for anything written here. A very good preparation of glycerine jelly is prepared by Mr. Rimmington, of Bradford, and by Mr. White, of Letcham, Norwich; the latter puts it up in a very convenient form.

† Abstract of a Paper in the *Archiv der Pharmacie*, for October.

has described this compound, but he says that it is not crystalline. He prepared it by mixing 240 parts of hydrochlorate of quinine with 460 parts of iodide of potassium in aqueous solution. After it had cooled a colourless turpentiny mass subsided, which in a water bath melted like a resin.

Acid Quinine Hydriodate.—$C_{20}H_{24}N_2O_2$, $2\ HI+5H_2O$.—Prepared by dissolving quinine in an excess of hydriodic acid. It crystallizes in golden yellow flakes. This salt has already been described by Hesse.

Quinine and Cinchonine Iodide.—$(C_{20}H_{24}N_2O_2)\ (C_{20}H_{24}N_2O)\ 2\ I_2$.—Equal parts of quinine, cinchonine, and iodine were rubbed together. The mass was uniformly coloured red-brown, the iodine reacting energetically. Treated with alcohol, only a trace of iodine, together with quinine and cinchonine, was dissolved. The residue not dissolved by the alcohol was insoluble in water also, slightly soluble in ether, and soluble in alkalies and acids. Under the microscope this double iodide of quinine and cinchonine showed a crystalline structure. The compound was readily decomposed by nitrate of silver, by the aid of which reaction the above formula was constructed.

Quinine Biniodide.—$C_{20}H_{24}N_2O_2HI_2$.—If solution of iodine in iodide of potassium be added to acid sulphate of quinine a voluminous kermes brown precipitate is produced, having the above composition. It is decomposed by long washing with water. Biniodide of quinine is soluble in alcohol and in iodide of potassium solution; also in ether, chloroform, and carbon bisulphide. It is especially soluble in boiling benzol. If it be dissolved in hot alcohol, and the alcohol be left to cool spontaneously, crystals are deposited, having a pretty bronze lustre. When dissolved in nitric acid the solution at first has a red colour, but afterwards becomes colourless. Is this due to an oxidation of iodine to iodic acid?

By a slight variation of the process the author obtained a body which in appearance was identical with the above quinine biniodide, but in relation to its solubility was essentially different. In this case the quinine salt was dissolved in alcohol, and to it was added an alcoholic solution of iodine. No precipitate was produced at first, but after long standing it threw down a flaky crystalline body, having a bronzy lustre. In form of the crystals, colour, and proportion of iodine it resembled the biniodide. On the other hand, it was slightly soluble in water, alcohol, ether, and carbon bisulphide; insoluble in benzol; difficultly soluble in chloroform. The alcoholic solution, heated for some time to 112° C., acquired an acid reaction. (Decomposition into hydriodic acid and some compound containing less iodine.)

Quinine Pentiodide.—The quinine biniodide was dissolved in alcohol, and thrown into an excess of alcoholic solution of iodine. After several days there was a non-homogeneous crystalline formation. Red-brown, almost black, prisms were surrounded by dark-coloured substances of almost pitchy consistence, from which, as far as possible, the crystals were separated mechanically; but attempts to separate the two bodies by different solvents entirely failed, both being soluble in alcohol, ether, and chloroform. The crystalline body exhibited interesting properties in polarized light.

The colour of quinine pentiodide in alcoholic solution is entirely changed by carbon bisulphide and potassium cyanide. Analysis indicated the formula $C_{20}H_{24}N_2O_2,HI_5$ (or 66 per cent. of iodine). The author, however, was unable in any way to prevent the formation of the pitchy product, and therefore looks upon the foregoing estimation, obtained by precipitation with silver nitrate as very imperfect, the crystals always retaining some portion of the impurity. But he considers there is proof that quinine can form a compound containing a large proportion of iodine, and he suggests that the constitution of this compound may be—

$$\overset{+}{Q}-I\begin{array}{l}\diagup I-I\\ \quad\ |\quad\ \ \|\\ \diagdown I-I\end{array}$$

Compounds of Cinchonine with Iodine.

Cinchonine Hydriodate.—$C_{20}H_{24}N_2O,\ HI+H_2O$.—Two parts of cinchonine were triturated with one part of iodine. The mass was coloured red-brown, the iodine reacting violently. Treated with 93 per cent. alcohol a portion was dissolved. Evaporation of the alcohol gave pale yellow crystalline needles, which were soluble in water, alcohol, and ether; traces were soluble in benzol and in chloroform. Analysis showed that the body so obtained was the hydriodate of cinchonine, already described by Von Regnault, v. Planta, Winkler, and Hesse.

Cinchonine Biniodide.—$C_{20}H_{24}N_2O,\ HI_2+2H_2O$.—When the mass formed by rubbing together two parts of cinchonine and one of iodine yields nothing further to alcohol, there remains a saffron-yellow body, crystallizing in scales, which is slightly soluble in absolute alcohol, ether, and chloroform, insoluble in water, cold and boiling benzol, and yields only traces to carbon bisulphide. The solution in absolute alcohol upon dilution with water throws down the body unchanged. From these properties the author considers this compound identical with Pelletier's cinchonine iodide.

Cinchonine Tri-iodide.—$C_{20}H_{24}N_2O,\ HI_3$.—Sulphate of cinchonine was mixed with solution of iodide of potassium containing iodine; it immediately yielded a voluminous red-brown precipitate. To this as much alcohol was added as was necessary to dissolve the precipitate. Upon evaporation the solution deposited red-brown crystalline prisms, which by exposure to light became brown-red. Cinchonine tri-iodide is insoluble in cold or hot water, very slightly soluble in ether, insoluble in cold and slightly soluble in hot benzol, insoluble in absolute alcohol and chloroform, and only yields traces to carbon bisulphide. It dissolves in sulphuric and nitric acids, with a red coloration. It is readily and entirely decomposed in the cold by nitrate of silver, the products being iodide of silver and nitrate of cinchonine; this reaction was used in calculating its formula.

(To be continued.)

THE DISPENSING OF MONOBROMATED CAMPHOR.

In an article in the *Practitioner* for the present month, entitled "Camphor and its Monobromide," Dr. Robert Lawson, of the West Riding Asylum, remarks upon the want of convenient forms of administering this compound. He says:—

"To begin with, it must be observed that the very limited solubility which characterises camphor is present to even a more marked extent in its monobromide. Not only so, but the high diffusive power which in camphor appears to compensate, in some measure, for its meagre solubility, seems to be much less characteristic of the monobromide. In sufficient quantities for the production of any marked result, camphor cannot be dissolved so as to remain in solution and be at the same time sufficiently bland for administration in anything but milk, and milk is a most inconvenient dispensing medium. In pills it is so bulky that scarcely more than two grains can be given in each, so that eight or ten pills require to be administered in a dose before much physiological effect can be looked for. Though an enthusiastic experimentalist might find no difficulty in overcoming the nausea which physic, quite as much in the abstract as the concrete, generally creates, and in swallowing ten large pills in succession, the performance would not recommend itself to a patient with a diminished appetite and a fastidious palate. Again: in mucilage, or in oils and fats, the drug would become most uninviting, and would most probably be rejected either before or after an attempt at deglutition. The same objections apply equally to the monobromide of camphor. In fact, it appears to me that in the case of the new drug they are intensified. The solubility of the monobromide in spirit is much less than that of the pure camphor; and as the monobromide is at once precipitated in an artificial gastric juice, there is every reason to believe that in any mode of administration it assumes the undissolved form in the stomach. Consequently, it must produce all those bad effects upon the mucous membranes which have been ascribed to camphor. With a candour which shows his desire to reach the truth, Dr. Bourneville admits that it does so when he concludes that 'the monobromide of camphor brings on in guinea-pigs and in cats a loss of flesh which, when the experimentation is carried on, soon occasions, in turn, a fatal termination.'

"Also with regard to hypodermic injection, it must be observed, as an important matter when determining the practical utility of the drug, that the marked insolubility of the monobromide of camphor renders it necessary to use so pungent an injection, and to make so many punctures, that unless some new bland solvent can be discovered for it, its use in medical practice must be deferred. Though I have not seen a single sign of suppurative or erysipelatous inflammation from the use of the injection prepared according to Dr. Bourneville's formula (and I have made fifteen consecutive hypodermic injections into one animal), yet it would be impracticable to use a hypodermic injection of a pungent character, of which several and perhaps numerous consecutive new insertions would be demanded before any beneficial result could be hopefully expected."

Dr. Lawson concludes the article by expressing a doubt whether either camphor or its monobromide will ever be favourite medicines, owing to their limited solubility, unless some means should be devised of introducing them into the stomach in a manner calculated to lessen their tendency to produce gastric irritation. *Dragées*, such as Dr. Bourneville refers to, are elegant preparations, but he thinks, as far as the tendency to irritation is concerned, they have no advantage over pills, and he is afraid that for hypodermic injection a more concentrated and more bland solution will require to be devised before the monobromide can come into general use. Still, the preparation is one which, in his opinion, possesses a value that will reward any reasonable amount of ingenuity expended in determining convenient methods of administering it.

THE PHYLLOXERA AND A NEW INSECT POWDER.*

M. Dumas has made a communication on this subject to the Paris Academy of Sciences, announcing the scientific solution of the question, and the approaching practical method of destroying this terrible insect.

In the meantime the pest continues its progress towards the north. M. Maurice Girard has reported to the Academy its ravages in the two departments of the Charentes; it is found everywhere in the environs of Cognac. Libourne is attacked in the most serious manner, and the pest has reached Châteauneuf and Angoulême. The progress of the creature is, however, capricious; one district of vineyards is attacked, while another, where the soil and kinds of vines cultivated are the same, escapes entirely. The insect is also reported to have appeared in Champagne, in Lower Austria, and in the environs of Geneva.

M. Dumas, noticing the unusual development of the winged phylloxera, remarks that it coincided with the holding of the insect exhibition in Paris, and complains that it was a very injudicious act to bring vines infected with the insects to Paris, and that it may cause the pest to appear in the vineyards around Paris and in the great grape-growing establishments in the Forest of Fontainebleau. Up to the present time, he says, the annual flight of the creatures has not exceeded 12 or 15 miles. They took two years to reach Burgundy, and much longer to arrive in Champagne. If Paris were infested by them, Burgundy would be placed, as it were, between two fires, Champagne would be seriously menaced, and all the grand *crus* of France would be compromised.

M. Lichtenstein believes that the vine phylloxera attacks and flourishes on the kermes-bearing oak, but M. Balbiani considers the oak insect a different one. Four varieties indeed are mentioned—those found respectively on the pedunculated oak, the white oak, the kermes oak, and the vine, but all but the last are considered harmless.

The period of hibernation of the phylloxera differs in hot and cold countries. M. Girard has observed near Cognac the influence of temperature on the insect. In the early days of October, when the weather was rainy at intervals, and rather cold, with white frost in the mornings, no eggs were to be found, but the warmer weather which followed caused their reappearance. In this they resemble other insects. It seems probable that the slower progress in northern vineyards may be due solely to a more prolonged hibernation, but without warranting the assumption that the cold will kill them completely.

The sulphocarbonates suggested by M. Dumas for the destruction of the insects are said to give certain results. He made experiments in his laboratory, first on the plants, and, secondly, on the insects themselves, and found that plants did not in any way suffer from being syringed with weak solutions of these salts, while the insects which were placed near the substances impregnated with the solution invariably perished.

M. Girard made experiments at Cognac with sulphocarbonate of potassium, prepared by the old costly method, and found that when some of this salt was placed at the bottom of a jar, and the insects introduced into the air in the upper part of the vessel, they soon died. As an insect powder he considers this salt as at least as effective as cyanide of potassium.

The next step was to procure it by a less costly method; and M. Dumas found that without the use of alcohol, hitherto believed to be necessary, the sulphide of potassium, dissolved in water, and the sulphide of carbon would mix when certain pains were taken. A wholesale manufacture of the salt was undertaken on this principle by M. Dorvault, and the necessary cheap materials procured for further experiment.

M. Monillefert undertook the experiments at Cognac. Vines in pot bore for a long time the effect of the solution without any injury, and, where phylloxera were present, they were all dead in a few days. The experiments were then extended to the open air, and it was found that plants of very different kinds were entirely unaffected by the solution. In the vineyards the effects were the same, or rather they were *nil*; and in the cases of infested vines the destruction of the insects was so complete and so rapid that M. Monillefert, who is well acquainted with all known insect-destroying substances, declares this solution to be the most powerful he has ever met with. It remained to be ascertained how deeply the solution would penetrate the ground; whether aged vines would support its application as well as those in full vigour; and, lastly, to find out the best method of applying the solu-

* From the *Gardeners' Chronicle*.

tion. It was found that from 30 to 40 grammes (1 oz. to 1¼ oz.) of dry sulphocarbonate of potassium, dissolved in water and poured into holes around the stem of the vine, destroyed the insects in the case of vines more than a century old without harming them in the least.

Another series of experiments had been made by M. Petit de Nismes, and others—namely, the application of coal tar, and with various results, when M. Balbiani took up the subject, and arrived at the conclusion that the tar which he used, obtained from the coal of Bességes, was a perfect destroyer of the insects. M. Dumas promises shortly a chemical and physiological analysis of this special coal tar; and M. Balbiani is now engaged in experiments with other sorts. It is not with respect to the phylloxera alone that careful experiments and investigations of this kind are valuable.

BOLDO.

Several notices which have appeared during the last few months in the medical and other journals have directed considerable attention to a new Monimiaceous medicinal plant, popularly called Boldo. It is an alpine shrub, met with frequently in the Chilian Andes, where the sweet mesocarp of its fruit is eaten; the bark is used in tanning, and the wood is esteemed for charcoal making. It has at various times been described by botanists under the names *Peumus fragrans*, Pers., *Ruizia fragrans*, R. et P., *Boldoa fragrans*, C. Gay, *Boldea fragrans*, Tul. But as it was described so far back as 1782 by Molina as *Peumus boldus*, Baillon considers this latter name has the right of priority. The properties attributed to the plant are that it acts as a stimulant to digestion, and has a marked influence on the liver. The discovery of these alleged virtues is said to have been due to the beneficial effects which followed the shutting up of a flock of sheep suffering from liver disease within an enclosure which had been recently repaired with boldo twigs. The sheep are reported to have eaten the leaves and shoots and recovered speedily. The leaves are the portion of the plant used in medicine, for the sake of an aromatic oil they contain; but up to the present time only a very small quantity, if any, has been received in this country. In France, however, the plant has been the subject of physiological and therapeutic experiments by Dr. Dujardin-Beaumetz, and of an elaborate investigation by M. Claude Verne, who has recorded his results in a thesis* presented upon his applying for the title of Pharmacien de la première classe in January last. To this thesis we are indebted for the details which follow.

Materia Medica.—The boldo tree, which formerly was met with only in the mountains, grows now upon the cultivated districts, and embellishes them with its green foliage and flowers of a yellowish white colour. It is never met with in a forest, but always grows isolated; in good soil its development is rapid. It is indigenous to the New World, and has a very restricted area, not having been met with outside Chili. This tree has a height of from five to six metres, and is an evergreen, having cylindrical branches bearing cylindrical opposite branchlets. The thin bark is adherent to the wood, corrugated longitudinally, of a clear brown colour, and very aromatic; the wood, on the contrary, is only slightly aromatic. The leaves, green when fresh, change in drying to a reddish brown. They are coriaceous, with prominent midrib, veins alternate, sometimes opposite, and covered on their surface with small glands. The leaves are opposite, entire, and oval, and when chewed leave a fresh aromatic taste; their odour recalls that of the Lauraceæ and Labiatæ. The flowers are diœcious, in racemes placed at the end of the branchlets, of a pale colour, and contrast well with the shining green leaves. The yellowish green fruit, which must not be confounded with that of the *Peumo*, or Boldu, of the Lauraceæ, sold in the markets of the country, has an aromatic, succulent, sweetish mesocarp, which is eaten, and the very hard kernels are made into necklaces by the Chilians. The first specimen of boldo leaves was sent into France, for experimenting in diseases of the liver, by the house of Fabian, of Chili.

In South America the plant is well known as an aromatic, and infusions prepared from it are prescribed as digestives, carminatives, tonics, and diaphoretics. It is also a popular remedy against syphilis and diseases of the liver. The dried leaf, reduced to powder, is used as a sternutatory.

In the small family of Monimiaceæ there are two other new plants, which are said to possess properties analogous to those of boldo, viz., *Atherosperma moschata*, Labil. and *Nenuraron Vieillardi*. The bark of the first in decoction is considered to be a powerful tonic and antiscorbutic. As a weak infusion, either alone or with milk, it is used instead of tea, and in that form has an aperient action. The bark of the second has a strong camphoraceous odour and intensely hot taste, and is chewed by the Kanacques as a digestive and powerful stomachic.

Histology.—The essential oil of boldo is contained in special cells, which are met with in nearly every part of the plant. The author had the opportunity of studying histologically portions taken from a tree growing in the botanical garden of the Ecole de Médecine, Paris. A transverse section of the limb of the leaf showed the following characters:—

The upper epiderm has one, two, or sometimes three rows of cells, especially in the neighbourhood of the insertion of some hairs which originate in the second row. These hairs are simple, rarely bifid, in form like birds' claws, conical, arched, and lie parallel to the surface of the leaves. The inferior epiderm, pierced all over with stomata, has but a single row of cells, and its stellate hairs, of the same form as the preceding, sometimes penetrate beyond the epidermic tissue into the parenchyma. The parenchyma is divided into two zones, one having oval-oblong cells, gorged with chlorophyll, the principal axis of which is perpendicular to the surface of the upper epiderm; the other having polyhedric cells, less green than the others, containing in the interior thinly scattered grains of chlorophyll. Both zones are furrowed by the fibro-vascular tissue proceeding from the nerves of the limina, and in the second moderately large lacunæ frequently occur. The vessels containing the essential oil are found principally in the latter zone; rarely they occur in the former.

The oil vessels differ in shape from the neighbouring cells, being perfectly spherical and of a greater diameter, and this form remains the same in whatever part they are found. There is no trace of chlorophyll in the interior, but sometimes the thick enveloping membrane retains small green granulations, and the rest of the cavity is filled with a refracting liquid. In places where this membrane has been cut by the razor its texture appears close, firm, and transparent, and the liquid may be seen protruding beyond the envelope. This liquid is white, and transparent in the green leaf; in the dried leaf it has a yellowish green tint, and does not fill all the cavity, being divided into little drops, imprisoned at the bottom of the organ.

Chemical Examination of the Plant.—Some leaves mixed with portions of the stem, coarsely powdered, were placed in a displacement apparatus, and treated successively with ether, alcohol, and distilled water. Treated with ether they yielded an essential oil (2 per cent.), alkaloid (trace), citric acid, and a considerable quantity of aromatic substances. To the alcohol they yielded a small quantity of essential oil, alkaloid (abundantly precipitated by double iodide of mercury and potassium), citric acid, sugar, and aromatic matters. To the distilled water they yielded sugar, gum, lime, citric acid, and tannin.

The most abundant product yielded by the plant is the

* Etude sur le Boldo. Thèse présentée et soutenue à l'Ecole Supérieure de Pharmacie de Paris, par Claude Verne. Paris, 1874.

essential oil, as much as two per cent. having been obtained in repeated operations. This proportion, however, is small, when compared with the amount of thick black aromatic matter which is left at the bottom of the retort, and is probably due to oxidation of the oil. In distillation, a certain quantity of oil, having an odour resembling that of the plant, passes over at 185° C.; the thermometer then rises gradually to 230° C., and after remaining stationary a few moments, rises to 300° C. The products of distillation collected at 230° C., and between 230° C. and 300° C., compared with the first product, have a greater density and a stronger odour, but the odour is always that of the whole plant. This shows that the volatile oil of boldo, like most vegetable aromatics, is a mixture of several bodies. It is worthy of note that the authors failed to obtain more than a trace of the oil by distilling fresh leaves and stems taken from a plant grown in Paris.

The essential oil has no reaction upon litmus paper. It is very slightly soluble in water, to which it communicates its flavour, and gives a slightly acid reaction. It is very soluble in rectified spirit, and the mixture will burn with a bright flame; alone it burns with a fuliginous flame. The crude oil is at first strongly coloured, but after rectification it loses its colour and becomes a clear yellow, and has a fresher odour. It does not form a solid compound with bisulphite of soda (no aldehyde). It is coloured hyacinth red by sulphuric acid, violet by nitric acid, red by potash, and is decolorized by hydrochloric acid. The addition of iodine causes at first a sharp effervescence; then the iodine disappears in the mass, which is coloured and considerably thickened.

The fact of the author, in conjunction with M. Bourgoin, having discovered in this plant an alkaloid—which they have named "boldine,"—and the method by which they obtained it have been already published in this Journal. See vol. iii., p. 323.

Pharmacy.—The following forms are suggested by the authors as suitable for the administration of the active principles of this plant:—

Alcoholic Extract.—100 grams of leaves coarsely powdered are exhausted in a displacement apparatus by 400 c.c. of 60° alcohol. The alcohol acquires a warm taste, and is reddish-black in colour. Evaporated, it gives twenty grams of dry extract, dark red, with a greenish tinge, and having a hot, sweetish-bitter taste.

Aqueous Extract.—100 grams of contused leaves are macerated during twenty-four hours, in a water-bath, with sufficient distilled water to leave 1,000 grams at the end of the operation. The macerate filtered has a reddish colour, a slightly sweetish-bitter taste, and gives upon evaporation in a water-bath 15 grams of extract.

Essential Oil.—As in other essential oils, the strong odour and burning taste render this oil difficult of administration. The author has prepared it in the form of *perles* containing each eleven centigrams of oil. He has also introduced an ethereal tincture into *perles*.

Tincture.—100 grams of contused leaves are macerated during eight days, with occasional stirring, in 500 grams of 60° alcohol, and filtered. The product is deep red, with a slightly green tinge.

Wine.—30 grams of contused leaves are macerated during twenty-four hours in 60 grams of 60° alcohol, and 1,000 grams of Madeira wine added. After eight days' further maceration, with occasional stirring, the marc is pressed and the product filtered. The wine possesses in a high degree the aromatic properties of the plant.

Syrup.—100 grams of contused leaves are infused during six hours in 1,000 grams of water in a covered vessel; they are then strained and pressed, and 950 grams of sugar added to the liquor, in which it is dissolved by the aid of a covered water-bath. This syrup is very aromatic, and appears to be easy of administration because of its agreeable taste.

Elixir.—200 grams of contused leaves are treated by displacement with 1,500 grams of 60° alcohol. The entire quantity of alcohol is recovered by the addition of a small quantity of water, the amount of which is noted. Afterwards the quantity of water is increased to 600 grams, with which a weak decoction is prepared from the exhausted leaves. With the decoction and 600 grams of sugar a syrup is made, which is mixed with the alcoholic tincture. After twenty-four hours the product is filtered through paper.

In the above preparations the leaves deprived of their stems, and the bunches of stems, sometimes bearing the flower, are employed. The young wood is also aromatic, and more bitter than the leaves.

These preparations are said to have been administered with success in the Hôtel Dieu and Hôtel Beaujon in cases of atony of various organs when the patients have been unable to tolerate quinine. Care, however, is required in their administration, as vomiting is provoked by large doses. Dr. Beaumetz commences with fifty centigrams of alcoholic tincture in a julep, and this dose may be increased to two grams daily. The dose of the more dilute and more agreeable wine is a spoonful to a wine-glassful once or twice daily.

PATENT BUTTER.

The following extract is taken from a letter of the Paris correspondent of the *Daily News*:—"Passing some days since along the Rue du Pont Neuf, I was pushed, by a crowd staring into the windows of what appeared to me a great butter-shop, from the foot pavement to the carriage road. I noticed on the shop front various inscriptions, such as 'More wholesome than butter,' 'Less than half the price,' 'Goes twice as far.' My curiosity to know what this wonderful product might be was very transient. I supposed the flaring announcements to be some kind of ingenious charlatanism, and thought no more about them. But subsequently I have read, not only in flaming advertisements, but in those much more highly-paid invitations to the public to spend money, elegantly written articles called *réclames*, an announcement that a discovery had been made of a substance which had not only all the good qualities of butter, but is devoid of the bad ones. It is never rancid or indigestible; and instead of keeping good for only a few days will last sweet for a twelvemonth. Had I only seen the shop I should never have gone into it, and had I only seen the advertisement I should not have been a customer of the shop. But chance having called my attention to both, I went, notwithstanding a deeply-rooted prejudice against scientific substitutes for staple articles of food, to No. 25, rue du Pont Neuf, and invested a franc and a quarter in the purchase of a pound of butter which is warranted not butter. There was still in front of the shop a crowd such as I had before noticed, but there were no customers inside. A comely damsel, who certainly did not suspect that I came as a suspicious critic, served me with what I asked for, and at the same time thrust into my hand a prospectus showing that the patented and mysterious substance, though hitherto it has made little noise in the world, has obtained medals at universal exhibitions. Why, since the invention is protected by a patent, should not the patentees tell the world what their product is made of? I can only suggest that if people knew what it was perhaps nobody would eat it. I have eaten of it, sparingly, cautiously, and I can certify that it is not bad. In colour and appearance it is precisely like butter. The taste has not that 'high celestial flavour' of the best butter I have known; but it is better than the average of what one gets. Nobody, not told, would suspect it not to be butter when spread upon a slice of bread. Whether the puff asserting it to be 'more wholesome than butter' be true, I cannot say, because, distrustfully, I have only taken very little, and I think of the Italian proverb, *Ve ne accorgerete domani.* But the stuff, whatever it may be, is too good to be wasted in a household, and is worthy of scientific investigation. The Octroi of Paris requires the patentee, who, it seems, has 400 workmen somewhere in the country, to pay the same duty upon his grease as is exacted for butter. There is a splendid opportunity now for servants addicted to *anse de panier*, as nine out of ten French servants are, to cheat their mistresses. They may safely put down butter in the housekeeping books at 3f. the pound, and get the wonderful counterfeit at 1f. 25c. I remember that some years ago a shop was opened in the Rue Cadet, which sold as better than wine an artificial product in which it was admitted there was not a drop of the juice of the grape. Notwithstanding this frank avowal the police shut up the establishment, as being calculated to deceive the public. The artificial butter has not hitherto been molested, and I do not see why it should be. Let it make its way by its own merits, of which I only speak tentatively."

PROFESSOR TYNDALL AND HIS CRITICS ON TYPHOID FEVER.

The consideration of a treatise by Dr. Budd on typhoid fever, in the light of the recent outbreak at Over Darwen, has induced Professor Tyndall to contribute to the *Times* a long letter, which purports to discuss the question —Can typhoid fever be generated anew? Is it produced by the decomposition and putrefaction of animal and vegetable substances, or must the matter producing it have had previous contact with an infected body? In other words, for every new case of typhoid fever may we with certainty infer a pre-existing case, of which the new one is merely the propagation or continuation, or are we entitled to conclude that organic matter, which has never been in contact with a typhoid patient, is, in virtue of its own decomposition, capable of starting the fever anew?

On the ground that this is a "question which is sure to occupy the attention of statesmen, as well as physicians," Professor Tyndall thinks it desirable that it should be stated in the clearest untechnical manner. This he seeks to do by summarizing some of the statements in Dr. Budd's book in the following manner :—

"Dr. Budd takes his reader to the village of North Tawton, where he was himself born and brought up, and every inhabitant of which was personally known to him. In the village there was no general system of sewers. Round the cottages of those who earned their bread with their hands, and who formed the great bulk of the population, collected various offensive matters. Each cottage, or group of three or four cottages, had a common privy, to which a simple excavation in the ground served as a cesspool. In many cases hard by the cottage door there was not only an open privy, but a dungheap, where pigs rooted and revelled. For a long period there was much offensive to the nose, but no fever. An inquiry, conducted with the most scrupulous care, showed that for fifteen years there had been no severe outbreak of the disorder, and that for nearly ten years there had been only a single case. 'For the development of this fever,' adds Dr. Budd, 'a more specific element was needed than the swine, the dung-heaps, or the privies were able to furnish.'

"That element at length came, and formed a starting-point from which its further progress might be securely followed. On the 11th of July, 1839, a case of typhoid fever, doubtless imported from without, occurred in a poor and crowded dwelling, and before the end of November eighty of the inhabitants had suffered from it, a proportion about the same as that now suffering at Over Darwen. The reader will, I trust, bear strictly in mind that the question now before us is, whether typhoid fever is contagious, and he is asked to weigh the answer which facts return to this question. Two sawyers living near the stricken house at North Tawton fell ill, and quitted the village for their own homes at Morchard, where no previous case of typhoid fever had been. In two days one of these men took to his bed, and at the end of five weeks he died. Ten days after his death his two children were laid up with the fever. The other sawyer also took to his bed, and when at the worst a friend from a distance came to see him, and assisted to raise him in bed. On the tenth day after this friend was seized with the fever. Before he became convalescent two of his children were struck down, and his brother, who lived at a distance, but who came to see him, also fell a victim. Was this series of events the result of chance, or was it the work of contagion? Let us pursue the inquiry further. On the 20th of August a Mrs. Lee began to droop at North Tawton, and, not knowing what was impending, she visited her brother at Chaffcombe, seven miles off. She was smitten with the fever, and before she became convalescent her sister-in-law, Mrs. Snell, who had nursed her, was attacked, and died subsequently. Then came Mr. Snell, then one of the farm apprentices, then a day labourer, then a Miss S., who had come to take charge of the house after Mrs. Snell's death; and, finally, a group consisting of a servant man, a servant girl, and another young person who had acted as nurse.

"The case here submitted to the reader is not one of medical practice but of common evidence, which does not even require a trained scientific mind to weigh it. Let us proceed. A boy who had been smitten at Chaffcombe went to his mother's cottage, between Bow and North Tawton. Before he recovered, his mother, who had nursed him, sickened, and afterwards died. Two children of the family next door were next attacked, then the sister of the boy who had carried the infection from Chaffcombe. She, in her turn, removed to another place, and became a new focus for the propagation of the disease. Again, to lighten the list of invalids a girl named Mary Gibbings was sent from Chaffcombe to her home at Loosebeare, four miles off. Here she lay ill for several weeks. Before she recovered her father was seized. A farmer who lived across the road, and who visited Gibbings, was next struck down. His case was followed by others under the same roof; and the fever, spreading from this to other houses, became the centre of an epidemic which gradually extended to the whole hamlet.

"At the same time, scattered over the country side, were some twenty or thirty other hamlets, in each of which were the usual manure yard, the inevitable pigsty, and the same primitive accommodation for human needs. 'The same sun shone upon all alike, through month after month of the same fine, dry, autumnal weather. From the soil of all these hamlets human and other exuviæ exhaled into the air the same putrescent compounds in about equal abundance. In some of them, indeed, to speak the exact truth, these compounds, if the nose might be trusted—and in this matter there is no better witness—were much more rife. And yet, while at Loosebeare a large proportion of the inhabitants were lying prostrate with fever, in not one of the 20 or 30 similar hamlets was there a single case.' There is no confusion of data here; no blur or indistinctness in the observer's vision, no flaw, as far as I can see, in his reasoning. He follows the morbific agent from place to place, sees it planted, developed, shedding its seeds, producing new crops; growing up where it is sown, and there only. Ashpits fail to develop it; putrescence fails to develop it; stench fails to develop it; even the open privy is powerless as long as it is kept free from the discharges of those already attacked."

After this evidence, Professor Tyndall thinks it impossible for any intelligent reader, and especially any man trained to scientific reasoning, to doubt that the "human body is the soil in which the specific poison of typhoid fever breeds and multiplies."

In conclusion, Professor Tyndall says :—

"On the 9th of June, 1871, I ventured to express myself thus :—'With their respective viruses you may plant typhoid fever, scarlatina, or small pox. What are the crops that arise from this husbandry? As surely as a thistle rises from a thistle-seed, as surely as the fig comes from the fig, the grape from the grape, and the thorn from the thorn, so surely does the typhoid virus increase and multiply into typhoid fever, the scarlatina virus into scarlatina, the small-pox virus into small-pox. What is the conclusion that suggests itself here? It is this, that the thing which we vaguely call a virus is to all intents and purposes a *seed*; that, excluding the notion of vitality, in the whole range of chemical science you cannot point to an action which illustrates this perfect parallelism with the phenomena of life—this demonstrated power of self-multiplication and reproduction.' It was the clear and powerful writings of William Budd, joined to those of the celebrated Pasteur, that won me to these views. It is partly with a view of stamping at a receptive moment salutary truths upon the public mind, but partly also through the desire of rendering justice to a noble intellect, which has been literally sacrificed to the public good, that I draw attention, not only to the masterly combination of observation and inference exhibited from beginning to end of Dr. Budd's volume, but also to the crowning fact already published in the medical journals, and to which my attention was first drawn by my eminent friend Mr. Simon, that Dr. Klein has recently discovered the very organism which lies at the root of all the mischief, and to the destruction of which medical and sanitary skill will henceforth be directed."

Professor Tyndall's intended contribution to the popularity of biological science has been most unfavourably received by the medical press, all the journals agreeing that he has failed to show that he is able to estimate at its proper value the evidence on the subject. The *British Medical Journal* says:—"It is not a little remarkable that a philosopher who maintains that even the human race has, by a process of evolution, in the course of countless ages, sprung from something lower in the scale of organization even than organisms, which he compares to 'drops of oil suspended in a mixture of alcohol and water,' and who seems to agree with Lucretius in affirming that 'nature is seen to do all things spontaneously of herself, without the meddling of the gods,' should yet maintain that the poison of typhoid fever can never arise except from a previous case of typhoid fever, and must therefore have existed from all eternity, before even man himself existed. Dr. Tyndall submits that the question at issue involves no knowledge of medical practice, but simply a capacity to weigh evidence. It seems scarcely credible, however, that Professor Tyndall can have carefully weighed the evidence on both sides, when he comes forward and asserts positively in the public press that typhoid fever is a most contagious disease, like small-pox, and can arise in no other way than by contagion. It may be hereafter shown that such is the case; but the statement is far from having been proved; and there are certainly strong facts on the other side, which demand that judgment in the matter shall be deferred, and which have an important bearing upon medical practice. If the excretions of typhoid fever be so eminently contagious as Dr. Tyndall asserts, it is difficult to account for the remarkable exemption from the disease of the attendants on the sick referred to by all medical writers."

Further, the *British Medical Journal* refers to the experience in the London Fever Hospital, as quoted by Dr. Murchison:—"During nine years 3,555 cases of enteric fever were treated in the same wards with 5,144 patients not suffering from any specific fever. Not one of the latter contracted enteric fever, although it was not an uncommon practice for them to sit over the evacuations of enteric patients, and the use of disinfectants was quite exceptional."

Respecting Professor Tyndall's "crowning fact," it is remarked "that it is surprising that a man of Dr. Tyndall's scientific position, an adept in weighing evidence, should exhibit such a want of philosophic caution as to crown his argument by the astounding announcement that 'Dr. Klein has recently discovered the very organism which lies at the root of all the mischief, and to the destruction of which medical and sanitary skill will henceforth be directed.' Dr. Klein's researches are still in embryo, and he himself would be the last, we believe, to make any such statement."

The *Lancet* designates Professor Tyndall's letter as "two-edged," and takes exception to a question which the Professor appends to an account of the cessation of an epidemic of fever after vigorous measures of disinfection, in which he asks:—"Can it be doubted that with sound medical advisers, backed by an intelligent population, an equally rapid destruction of the foe might be accomplished at Over Darwen?" The *Lancet* remarks, "If Professor Tyndall had communicated with Mr. Simon, or had read his memorandum on 'Disinfection' before giving publicity to this sentence, he would have learned that not only could it be doubted, but that an overwhelming amount of evidence exists that no such confidence can be reposed in the effect of disinfectants in arresting the spread of typhoid fever as he supposes. Disinfection is of value simply as ancillary to other more fundamental measures of prevention. In whatever manner practised, under conditions like those existing at Over Darwen, it is a sham, and nothing more. The whole teaching of sanitary experience during the last ten years, and in the full light of Dr. Budd's observations, has been to the effect that the spread of typhoid fever can alone be surely limited by the removal of those states of excremental pollution of soil, air, and water which admit of dissemination of the disease. Professor Tyndall's observation furnishes the sanitary authority of Over Darwen with another excuse for postponing the much-needed sanitary amelioration of the place."

The tone of the opinion expressed in an article in the *Medical Times and Gazette* may be inferred from the last sentence, which runs as follows:—"'Let the shoemaker stick to his last,'—let Professor Tyndall attend to his beams of light, and those phenomena about which he can at least speak intelligibly, and leave biological inquiries to those who have been trained to pursue them."

The discussion has, of course, not been confined to the medical profession. Amongst others, "A Promising and Potential Molecule" thus wittily "chaffs" the Professor in the *Times*, anent the ground he took in the Belfast address:—

"I consider I am receiving very unfair treatment at the hands of Professor Tyndall. Only the other day he recognized in me 'the promise and potency of all forms of life,' and introduced me to the notice of the British Association in particular, and society in general, as sufficient to account for all the vitality and intelligence to be found in the universe. And now in this discussion he is raising about typhoid fever, which he appears to regard as the product of an 'organism,' he gives me the cold shoulder, holds that he cannot fairly be asked how this organism began, and, adopting the language of Sir Thomas Watson, denies that 'filth, foul air, and the gaseous products of animal and vegetable decomposition ever produce a contagious fever,' or, in other words, the organisms which give rise to such fevers. I submit, after having so recently been the means of extending far and wide the fame of Professor Tyndall, that it is not very grateful or generous in him to leave me entirely out of account now. If I, by my inherent structural and other force, am capable, as he insinuated I am, of constructing a globe and clothing it with life and beauty, I think it very illogical, to say the least of it, to maintain, as he now does, that even with the proper combinations of filth, over-crowding, decomposing matters, putrid water, and so forth, I cannot originate and *de novo* construct so paltry an organism as a typhoid fever germ. Professor Tyndall had no right to exalt me so high as he did, and then, when the ecclesiastical dust which he raised about me is subsiding, to spurn my powers and capabilities in so small a matter as this."

PHARMACEUTICAL DUTIES FROM A MEDICAL POINT OF VIEW.

CAREFUL consideration of the troubles and difficulties of our neighbours may often serve as a useful lesson to ourselves, and as a warning against incurring liability to similar disagreeables. A case of this kind has lately presented itself in a discussion carried on in America in reference to certain points of pharmaceutical ethics, and *à propos* of the feeling that has been manifested in some quarters at home to disparage the effort to attain and maintain a high standard of pharmaceutic efficiency, it may not be altogether useless to reproduce here the chief features of the case we refer to.

The discussion to which we refer arose out of a proposal to establish at St. Louis, in the State of Missouri, a joint-stock company, under the title of the "Apothecaries Hall Association." The objects of the Association, as set forth in a circular inviting persons to become shareholders, were, generally, the manufacture, purchase, and sale of chemicals, drugs, and pharmaceutical preparations, as well as instruments, appliances, and apparatus used in surgery; also the compounding of medicines and dispensing prescriptions of medical men. As incidental to these main objects, measures were to be taken to ensure purity in all drugs, chemicals, and articles of the materia medica, as well as uniformity in the strength and quality of the standard preparations of the Pharmacopœia. It was also proposed to establish a scale of prices on the basis of gratuity to the poor, moderation to the public, and equity to the medical profession.

The pharmacies to be established at such places as might from time to time be selected were to be managed by pharmacists and chemists of approved competency and skill, and they were to be under the direction of the medical profession.

As regards the objects here set forth, there can be little question that they are good and desirable; but the proposal to establish a special corporation for their attainment obviously involves the assertion, or at least the suspicion, that they are not generally or sufficiently sought for under existing circumstances. In reference to this point, a writer criticizing the proposal in the New York *Druggists' Circular*, objects to the formation of such an association, on the ground that there is nothing to warrant such inferences as may be drawn from the wording of the circular in question. He declares that there is no necessity for such an organization in order to attain the objects set forth, since the local pharmacists are perfectly competent to accomplish all the desirable objects referred to by the projected association.

The writer of this criticism, signing himself "P. W. B.," further urges that such an organization would compromise the dignity and honour not only of pharmacists but also of medical men, and that, as regards the direction of such a business being placed in the hands of medical men, they would as a rule be wholly incompetent to carry it out.

In a subsequent number of the *Druggists' Circular*, Dr. JULIAN BATES, of St. Louis, comes forward with arguments in reply to the above-mentioned writer, who is assumed by him to be Mr. P. W. BEDFORD, the Professor of Pharmacy in the New York College. After indicating that among those who originated or favoured the project of joint-stock pharmacies there were reputable medical men, highly and justly esteemed by the medical profession, by pharmacists, and by the general public, he goes on to the question whether there are such abuses to be corrected in the conduct of pharmacies as would call for organizations like the proposed Association. He maintains that since the life of the patient, the reputation of the prescriber, and all intelligent progress in therapeutics, often hinge upon the skill and faithfulness of the dispensing chemist, physicians are not stepping out of their own sphere when they scrutinize and commend or condemn—as the case may demand—those who come always between the prescription and the patient, and in whose hands is the power to determine whether the patient shall or shall not have the treatment prescribed by the physician.

On these grounds he defends the attempt to establish pharmacies where only adult and expert dispensers will be employed in making up prescriptions, where only the articles and instruments used in the management of the sick should be sold, together with such chemicals of familiar domestic use, or serviceable in arts and manufactures, as, from their nature, may be expected to be found in a pharmacy. The miscellaneous merchandise, and the nostrums forming a large and lucrative part of the stock in trade of many dispensing establishments, Dr. BATES regards as constituting a serious abuse of the pharmacist's calling, and he urges that, by excluding such business from the pharmacies of the Association, the directing and dispensing druggists would have more time for the study of their calling and for due attention to the prompt and accurate compounding of prescriptions, since they would not be diverted by the study of prices of a manifold and promiscuous merchandise, and by the constant efforts to conciliate and retain remunerative traffic in heterogeneous articles foreign and unfriendly to the faithful preparation of medical prescriptions.

As regards the City of St. Louis, it is asserted by Dr. BATES that in many cases the dispensing of prescriptions is intrusted to unskilful and unsuitable hands, that there is a large engagement in various trades and in the sale of nostrums or quack medicines; also that some druggists, without any pretence or profession of preparation therefore often prescribe for the sick, while for medicines furnished on prescription of physicians, prices exorbitantly high are often demanded. He contends that for those druggists who are upright men, as well as expert and proficient pharmacists, avoiding the evils he enumerates, the enterprise he advocates would not be hostile but helpful, as tending to concentrate and confirm the public confidence in establishments conducted on a method so manifestly right.

As regards the competence of the St. Louis pharmacists to accomplish all the objects which the Association aim at, Dr. BATES admits entirely what "P.W. B." asserts, but he asks are they doing it? Will they do it? Lastly, while expressing a hope that the leaders of pharmaceutical opinion may exercise such an improving influence as would leave no room for complaint, he declares his conviction that if pharmacists fail to effect such reform "in their own ranks," it will be brought about by other methods.

The particular circumstances here referred to are too local and too remote from our appreciation to admit of the unreserved adoption of the views put forward on either side; but we think the discussion affords material for reflection, and for suggesting to pharmacists the necessity of making full provision for holding their own.

CRYSTALLOGRAPHY.

IT is announced that Professor MASKELYNE has offered to give a short course of lectures on Crystallography, commencing on the 23rd inst., if a sufficient number of the members of the Chemical Society, intimate to Dr. RUSSELL their intention of attending. It is the intention of Mr. MASKELYNE to treat of his subject with as small an amount of mathematical detail as is consistent with its proper development. The lectures will be open to anyone introduced by a Fellow of the Chemical Society.

CANTOR LECTURES.

THE Council of the Society of Arts announces that it has made arrangements for the delivering of the following courses of Cantor Lectures in the forthcoming session:—"Alcohol, its Action and its Use," by Dr. B. W. RICHARDSON, F.R.S.; "The Material, Construction, Form, and Principles of Tools used in Handicraft," by the Rev. ARTHUR RIGG; and "Some of the Forms of the Modern Steam Engine," by F. J. BRAMWELL, F.R.S.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

November 18th, 1874.

Present—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Two candidates were examined. Both passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Stamps, Frederick..................West Bromwich.
Adams, William ....Barnstaple.

MINOR EXAMINATION.

Fifteen candidates were examined. *Eleven* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists:—

Newton, Alfred Henry ....Kenilworth.
Harrington, Arthur ....Needham Market.
Simpson, Charles Alfred ....Fenton.
Price, Robert John ....Wrexham.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

Certificates as undermentioned were received in lieu of this Examination:—

Certificate of the Society of Apothecaries.

Allsworth, Norman ....Havant.

Certificate of the University of Cambridge.

Gostling, Thomas P. ....Diss.

Certificate of the University of London.

King, Edward Albert Godfrey...Southsea.

Certificates of the University of Oxford.

Hunt, Ince Harry..................Hendford.
Stukeley, Edward Charles ......Gloucester.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The first ordinary monthly meeting of the session was held on Wednesday evening, Nov. 11, Mr. Councillor Brown, President, in the chair. Mr. Gibson was elected a member, and Messrs. Newlove, Rosson, Blain, Allen, Illesley, Benson, Gant, Moss, Bond, Baxter, Dawson, Fletcher, and Nicholls as Associates.

The Chairman, in calling on Mr. Siebold to deliver the first of his special course of lectures, "On the Analysis of Common Articles of Food and Drink," said that though in past sessions gentlemen had always been found willing to provide lectures or papers for the monthly meetings, it had often been with considerable difficulty. This year, however, Mr. Siebold had most generously stepped forward and relieved them from all anxiety on this point by promising a series of lectures which he was sure would be most interesting and instructive to them all. These lectures would be given on the second Wednesday in every month, and would occupy about three-quarters of an hour each, after which the meeting would be open for the discussion of any matters of interest to the Association members might bring forward. He was very glad to see that such a large audience had assembled.

Mr. Siebold said his first lecture would be devoted to an examination of water, which, though not liable to adulteration, was always more or less impure; and the question to be answered was always whether these impurities were of such a nature, or existed in such quantities, as to render the water unfit for use. He should endeavour in his lectures to describe those tests which might be applied by the average chemist and druggist, and though in some cases these might be less delicate than more elaborate and laborious ones, they would be found sufficiently reliable.

A sample of water should be first examined as to its colour. A clear white glass flask of it should be compared with a similar flask of pure distilled water. It should be colourless. Next as to its smell: if no odour be apparent when cold, it should be raised to the boiling point, when it should still remain odourless. Lead might always be detected in the Manchester town's water, which was contaminated with this metal to the extent of about one-tenth of a grain per gallon. Though this quantity was not considered to be injurious to health in ordinary cases, it was quite possible that some persons might be affected by it. Water containing half a grain of lead per gallon might be unhesitatingly declared unfit for human consumption. Lead existing in water to this extent might be detected as follows:—Place four ounces of the water in a white glass flask, add a few drops of pure sulphuric acid, and boil; then add some fresh, clear solution of sulphuretted hydrogen, when a brownish colour will be produced should the water contain an injurious quantity of lead. The object of boiling the water with sulphuric acid is to decompose any nitrites which might possibly be present, and would produce a turbidity by precipitating some of the sulphur of the sulphuretted hydrogen, and this might obscure the reaction with very small quantities of lead. Copper is occasionally present in water, and would produce a similar coloration to lead, with sulphuretted hydrogen, but the precipitate (sulphide of copper) would be soluble in cyanide of potassium, which is not the case with the lead precipitate.

Nitrites indicate the presence of sewage or the products of the putrefaction of organic matter, and may be detected by placing four ounces of the water in a flask, and adding a mixture of iodide of potassium, starch paste, and acetic acid (this latter mixture should be colourless; if the iodide contain iodate it will be tinged and unfit for use). A blue colour will be produced if nitrites are present, the nitrous acid liberated from the nitrites decomposing the iodide of potassium, and the free iodine forming blue iodide of starch.

In the above test acetic acid is preferable to sulphuric, as the latter would liberate nitric acid from any nitrates present, and this, in the presence of organic matter, would be reduced to nitrous acid, and give a false indication of nitrites.

Nitrates do not necessarily indicate sewage contamination, as they are frequently derived from mineral matter, but when they co-exist with small quantities of nitrites and ammonia in water, there is good reason to suspect that they may have been derived from nitrites, and the water should be condemned. They may be detected by adding a little sulphuric acid and powdered zinc to a sample of the water, and then a little of the iodide and starch solution; the hydrogen evolved will reduce the nitric to nitrous acid, and give the blue coloration.

Lime and magnesia render water hard. In small quantities they are not injurious. To half a test-tubeful of the water to be tested add a little solution of carbonate of soda and caustic soda; a decided cloudiness would then show too large a proportion of the impurity. What is called temporary hardness is due to bicarbonate of lime or magnesia, which on boiling is reduced to carbonate and precipitated. Permanent hardness is due to sulphates and chlorides of these bases. Lime and magnesia may be very easily estimated quantitatively in water by Clark's soap test, which every chemist and druggist knows by name. The original formula proposed by Mr. Clark is now somewhat antiquated, and the modification suggested by Mr. Wanklyn and others is now generally adopted. It depends on the fact that when a solution of soap is mixed with water containing salts of lime or magnesia the soap is decomposed, yielding an insoluble compound. The amount of lime present is best estimated in the following manner:—To 70 cubic centimetres of the water in an 8 ounce white stoppered bottle, add the soap test by means of a burette, one cubic centimetre at a time, thoroughly shaking the bottle after each addition. So long as no permanent lather is formed, the whole of the lime has not been removed, but as soon as the froth formed by shaking the bottle stands two or three minutes, the quantity of soap test used must be read off. Each cubic centimetre corresponds to one grain of carbonate of lime, or its equivalent of chloride or sulphate, per gallon. In the specimen of water used to illustrate this test to the meeting, 11 c.c. of the soap test had been used; the water, therefore, contained 11 grains of carbonate of lime to the gallon, or, as it is sometimes expressed, was of 11 degrees of hardness. If more than 17 c.c. of the soap test be required, it is best to mix the water with an equal volume of pure distilled water before adding more of the test, but as one c.c. of the soap solution is required to produce a permanent lather with 70 c.c. of pure distilled water, one c.c. must be deducted in this case from the quantity read off from the burette at the end of the experiment.

Water containing 25 grains of lime salts to the gallon is unfit for use.

More than a trace of ammonia should never be overlooked. Nesler's test, which is one of the most delicate known, should give only the *faintest* yellowish red tinge to four ounces of the water in a clear glass flask. Any darker colour, or the formation of a precipitate, would indicate an unwholesome water.

Organic matter may be easiest detected by the permanganate of potash test. Frankland's and Wanklyn's processes are too difficult, and require too much practice to be of much use to the ordinary chemist and druggist. It is best applied as follows:—Heat 16 fluid ounces of distilled water to the boiling point, and add, by means of a glass rod, sufficient solution of permanganate of potash to tinge the water a delicate pink (the strength should be such that when one part of this water is mixed with three parts of distilled water the colour should be just discernible). To eight ounces of this hot distilled water and permanganate add four ounces of the water to be tested; if the colour is discharged, organic matter is present. Ferrous compounds and nitrites will also destroy the colour of permanganate. Should the former be present in the water to be tested, it should be boiled with a little nitric acid to raise them to the ferric state. Nitrites should be removed by boiling with a little sulphuric acid.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

The second meeting of the session was held in the West Hall, Anderson's University, on Wednesday, November 11, at 9 p.m., the President, Mr. John C. Hunter, in the chair. There was an average attendance of members. The minutes of the last meeting having been read and confirmed, the Chairman introduced Mr. William Currie, who read a paper on "Bleaching."

At the close of the paper the Chairman proposed a hearty vote of thanks to Mr. Currie for his very valuable paper, which was unanimously agreed to. The following gentlemen were elected members of the Association:—Messrs. A. Cowan, D. Cassels, G. A. Marrs, D. McGillvray, J. Rait, J. Campbell, W. Lawson, B. T. Connolly, and J. M'Nicol.

Messrs. Hunter and Murdoch reported having called upon the gentlemen who were discontinuing the early closing movement. The members would be glad to learn that they promised to be more prompt in future.

A few more members having been enrolled for the tutorial and chemistry classes, the meeting was brought to a close.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of this society was held at the Cross Keys Hotel, on Thursday evening, November 12, the President, Mr. Anthony Smith, in the chair. The report was read by the Secretary, Mr. C. B. Bell, and adopted. The financial position of the Society showed an increase on last year's balance. The election of officers for the ensuing year took place by ballot, with the following result:—President, Mr. Anthony Smith; Vice-President, Mr. Geo. Myers; Hon. Sec. and Treasurer, Mr. C. B. Bell; Committee, Messrs. Grindall, Jubb, Oldham, and Earle.

The President, in thanking the members for the compliment they had paid him in electing him to the chair for the third consecutive year, stated that he re-entered upon the duties with some degree of hesitation, as he considered two years should be the maximum time allowed for the same President to occupy the chair, but as it was their wish, he should continue in that position. He assured them that he felt most warmly the proof of their confidence, and no exertion on his part would be wanting to ensure the success of the Society, and to increase the facilities for the instruction of the rising generation in the trade.

Mr. C. B. Bell thanked the members most heartily for the confidence they had always reposed in him, and for again electing him to the office which he had held since the formation of the Society six years ago, and he trusted the usefulness of the Society would continue to increase.

Thanks were recorded by the members present to the past officers of the Society for their services, which were duly acknowledged.

The annual dinner was fixed for the first week in December.

CHEMISTS AND DRUGGISTS' ASSOCIATION OF IRELAND.

A meeting of this Association was held at 44, Molesworth Street, on Monday evening, November 16, Mr. J. T. Holmes in the chair. The minutes of the previous meeting having been read and confirmed, the Honorary Secretary said the principal business was to make final arrangements about the classes. The Secretary was requested to procure rooms in a central position; until then, through the kind offer of Professor Tichborne, the classes will be held in the Carmichael School of Medicine. On the motion of Mr. R. Watson, seconded by Mr. Goodwin, it was resolved that the class books recommended by the Pharmaceutical Society should be used.

Several new members were admitted, and about forty have already joined the classes, which promise to be quite a success.

SOCIETY OF ARTS.

Carbon and certain Compounds of Carbon.*

BY PROFESSOR BARFF.

(*Continued from page* 396.)

Lectures IV. and V.

It is generally known that coal was originally wood—*i.e.*, vegetable matter—which, under excessive pressure in the presence of moisture, and at a suitable temperature, has become slowly converted into the substance which is now called coal. There are various ways in which the formation of coal is accounted for—first, by the elements of water leaving the vegetable matter, then by the carbonic acid, and then by the marsh gas being given off. It is most probably formed by the loss of all these. What would be the result of wood or vegetable matter losing the elements of water? The composition of cellulose, the principal constituent of vegetable matter, is $C_6H_{10}O_5$. If from two molecules one molecule of water is taken there will remain $C_{12}H_{18}O_9$. It must be manifest that this compound would contain more carbon than the other did in proportion to its other constituents, and if the same thing be repeated, doubling the formula of the new substance, and taking away the elements of water from it, we shall at last get a substance known under the name of anthracite coal, which contains about 94 per cent. of carbon, and we could even imagine the process going on so far that eventually pure, or nearly pure, graphite would be left. Here, then, it is quite easy to conceive how such changes as these effect the decomposition of woody fibre, and convert it into that substance which is called coal. Again, carbonic acid and marsh gas are given off during the process, so that the loss of these two would change the composition of the woody matter, and produce a substance which would be rich in carbon compared to the substances from which it was originally formed. We may, then, imagine this to be the chemical method in which coal is formed. That it is of vegetable origin there can be no doubt. More than 500 different kinds of plants have been found in coal, and 250 ferns of the most beautiful structure. That it was once submerged beneath the ocean is not only not improbable, but it is almost absolutely certain, for we find in the coal traces of a substance which must have come into it in some such way as this. Sulphur is found there, and iron pyrites. From whence could the sulphur come? Probably from the sulphates of the sea—from the sulphate of calcium which got reduced by the action of marsh gas, for marsh gas, like hydrogen, is a reducing agent, so that at last, in the presence of the iron which was there, sulphide of iron or iron pyrites would be formed, which contains 56 parts by weight of iron, and 64 parts by weight of sulphur, and is a bisulphide of iron. It is in this way that this substance, which is a trouble to the ironmaster and ironfounder, came into the coal; and it is a matter of great importance to all who have to carry on, by the aid of heat from coal, delicate chemical operations where the presence of sulphur is injurious. Although the ironmaster may select his iron ores as free from pyrites as possible, if he use coal containing sulphur, sulphur will be present in the iron, and it is a most injurious substance to have in iron. A means by which sulphur can be readily eliminated from fuel is still a desideratum.

Coal is of different kinds; there are coals that will cake, and coals that will not cake. The coal which will cake is usually what is called bituminous. Many substances are got from the earth under the name of coal, from bituminous shale down to substances which are very little better than fireclay. Householders can form an opinion as to the quality of coal from the appearance of it. Some coals are brittle and break readily, and have a shining surface. These appearances are promising, and generally denote that the coal will burn well. Then there are those which have a slatey appearance and break in laminæ. These, as a rule, are not such good coals, and not such economical ones for use. They are generally found to contain a large percentage of ash or cinders, not that cinders are the ash of coal really, because in cinders there is a large portion of combustible matter very often thrown away. The coal which contains most bituminous matter is the Boghead cannel coal. It is found in the neighbourhood of Wigan, and in small quantities in some other places. It is known to be a very bright-burning coal, and is used when it is desired to produce a bright blaze and a cheery light. When burning it crackles, and the pieces fly about, not out of the grate but in the fire. A peculiarity of it is that its fracture is square and laminated if broken in one way, but conchoidal if broken in another. It is a coal which may be polished, and which is used for making ornaments in imitation of jet; the difference

---

* Abstract of a course of Cantor Lectures, delivered before the Society of Arts.

being, however, that they are heavy, whilst those made of jet are light. Anthracite coals vary in their composition and in their usefulness for household purposes. South Wales anthracite contains about 90 or 94 per cent. of carbon; the coal obtained in Munster, Carlow, and other provinces of Ireland contains a very large quantity of sulphur. The better kinds of anthracite contain about ·9 per cent. of sulphur, or nearly 1 per cent., but there are many varieties which contain a much larger percentage, even as high as 2½ or 3 per cent. It is quite manifest that for any metallurgical and other purposes of that class, coals containing sulphur must be very injurious; and also for making gas.

The heating property of coal, and how practically to determine that heating property, is an important subject. If several samples of coal be first weighed, and then burned perfectly, so as to burn away every trace of carbon, hydrogen, and oxygen from them, and leave nothing but ash behind, and the ash then weighed, the relation between the weight of the coal and the weight of the ash may be ascertained. The ash contains a silicate of alumina, some oxide of iron, sometimes traces of oxide of lead, the principal constituents being silicate of alumina and oxide of iron. A gentleman experimenting on this subject has come to results which lead him to believe that the heating powers of average coal are inversely in proportion to the ash—the less ash the greater heating power. If this be true, and there is no reason to doubt it, it would be very easy to determine the heating power of coal. Persons in private life could easily have an apparatus made by which they could burn away the coal and weigh the ash. All that would be wanted is a fireclay cylinder open at both ends, through which a current of air would pass. Then, if the coal were put into a porcelain dish, after having weighed it with accuracy, and the air allowed to pass through while at a red heat, the whole carbon, oxygen, and hydrogen would pass off, and there would be nothing left but the mineral residue, which could be weighed.

But there is another extremely interesting method of determining the heating power of coal. This method was described by the lecturer as follows:—

"In this glass vessel I have a known volume of water—two litres. In this small copper cylinder there is a known weight of coal, which is mixed with certain substances, which at a high temperature will give up their oxygen to it, and will burn it; for it is not necessary in all cases that we should have air, or the gases of air, to burn such substances as coal; we can put with it substances containing oxygen which will part with their oxygen readily, and thus, at the proper temperature, carbonic acid gas and water are formed, and a perfect combustion of the coal takes place, as perfect as in atmospheric air. We have a known weight of coal here, and we have a powder containing enough oxygen to burn that coal, and when that coal has been burned it will have given out all the heat which it can give out. I may mix it with chalk or with lime, or with anything else, but it will not make it give out any more heat. There is a certain quantity of carbon, which on burning will give out a certain quantity of heat, and a certain quantity of hydrogen which will give out a certain quantity of heat, and no more. Around the bottom of this cylinder there are holes to allow the escape of the gases generated in the combustion of the coal, and the whole of the heat will be communicated to the water. There are, however, certain sources of loss of heat, which have been tested, and it has been found by experiment that these losses, by radiation from the vessel, etc., amount to 10 per cent. Therefore, when we have determined the heating power of the coal according to the best of our ability by this apparatus, we have to add to it 10 per cent. The first process is to take the temperature of the two litres of water in this vessel, which appears to be 16° C. Then the coal is ignited by means of a piece of tinder at the top of the cylinder, and it is then lowered into the water, and you notice there is immediately a violent action going on under the water. The whole of the heat, minus the 10 per cent., which will be lost, will be transferred to the water, and on removing the cylinder, and again inserting a thermometer, we shall find the rise of temperature in the water."

Although this experiment gives very satisfactory results, it would be much better if the heating power of coal could be determined by simply burning it down to an ash and weighing the residue. At the close of the combustion the temperature of the water was 24°, so that there had been a rise of 8° in the temperature. It is usual to take as a unit of heat the amount of heat which will raise the kilogramme of water 1° C. The temperature of two kilogrammes of water being raised 8°, there has been as much heat given off as would raise 16 kilogrammes of water from zero to 1° C, or sixteen thermal units. In this way it is easy to determine the heating property of coal, or any other substance.

There are other fuels used besides coal. Peat is used as fuel in the ordinary form and in the compressed form. The difficulty that has been met with in introducing peat as a commercial article, at such a price that people will purchase it and use it, is that it occupies so much bulk, and there is a difficulty in compressing it. The water contained in bog peat is in little cysts, as it were, and in submitting it to pressure we have, in fact, to fight against incompressible water. The only way is to cut it up, and that is now done by rotating knives; when so cut up it can be compressed. Of course there would be an advantage in using peat fuel for certain purposes, because it does not contain sulphur, as coal does.

What are the effects produced by sulphur in coal? In the country villages in Carlow the people burn anthracite coal, and, if asked whether they like it, they will tell you it gives a very hot fire when it is lighted, but it is very difficult to light, and that they cannot use iron fire-bars because the sulphur burns away the iron. The effect of sulphur in coal is to destroy iron or copper. The effect will therefore be to corrode the metal pipes and small fastenings in connection with the engines through which the vapours pass, and it is therefore most desirable that sulphur in coal should be got rid of. Another effect which it produces, and which is experienced when travelling in railway tunnels, is the offensive odour that it gives off. That offensive odour is not always owing to sulphurous acid, but sometimes to sulphuretted hydrogen; but in railways, where they are obliged to condense their steam during their passage through the tunnels, and when the products of combustion pass out dry from the chimney into the tunnel, the sulphurous acid is manifested in all its vigour. It comes out mixed with a large proportion of carbonic acid. The question arises, Is this substance injurious to health? It certainly is most offensive, but is it injurious? It is stated that when sulphurous acid is breathed in large quantities it stops the breathing, and produces asphyxia; and when breathed in small quantities it produces catarrh. "It is quite certain," said the lecturer, "that the perpetual irritation of the mucous surfaces in persons who have a tendency to disease of the lungs must be most injurious. I cannot speak on this subject without deep feeling. I see people on the Underground Railway suffering manifestly from the inconvenience produced by the inhalation of this most injurious gas, and I myself have suffered from it continually. I have to go early in the morning to give lectures in the City twice a week, and frequently I am so affected by it that it takes me some time before I can recover myself to give my lecture with ease and freedom. Such a thing as this is shocking. We are compelled to travel by that line; ought we not, by our opinion manifested here, and by public opinion generally, to compel the directors of it to do their best to remedy this, not nuisance only, but this serious evil? I have received a communication from a neighbourhood where manufacturing processes are carried on by which means this gas is evolved, and I am told in that neighbourhood that, although diseases which are called epidemic are generally absent, yet diseases of the lungs increase wonderfully, and they are very serious in their results. There is no doubt about it. I know very well that you might get persons to say that there is no very great harm in it; that a little of it can do no harm. But a little of it can do harm; and there are many medical men, I am perfectly certain, who would be willing to come forward and state their opinions that disease might not perhaps be originated by it, but when produced would be increased by the inhalation of this gas. I should not speak so strongly about it as I do if it were not possible to remedy it. But the thing which has made me feel most strongly about it is this, that when ways and means for remedying it have been suggested to the directors of the company, they would not even try an experiment. Five years ago I performed an experiment in the presence of Mr. Burnett, their then engineer, which I will repeat for you to-night. I burnt in his presence, in a small room, a vessel full of pure brimstone, and he was unable to detect the smell of sulphurous acid. After that, when the means are very simple, when the scientific principle is not a complicated one, one might imagine that at least the company would give directions that some experiments should be tried to see whether it was successful. But as far as I know none have been tried; in fact, I am sure none were tried, for I saw some of the directors two years after, and I knew from one of them that none had been tried."

Sulphurous acid is a gas which readily unites with bases, formings salts called sulphites. Sulphurous acid is a strong-smelling substance, but sulphites have no smell of sulphur. The conversion of sulphurous acid into a sulphite is easily accomplished by causing it to pass through a tube in which there are lumps of coke saturated with caustic soda. The sulphurous acid readily unites with the hydrate of soda, and forms sulphite of soda. Coke contains at least one-half per cent. of sulphur, which is somewhere about 10 lbs. per ton. If 10 lb. weight of sulphur he burnt, it forms a very large quantity of sulphurous acid, and that large quantity must without doubt work an injurious effect upon the health of railway passengers who suffer from weakness in the lungs; at all events, it produces considerable discomfort to all travellers; and if it only did this, it is the duty of the managers of that railway to try and remedy the evil. There is not the slightest doubt they can do it if they take the proper means; the means already tried only very partially remedy it.

Now, to pass on to liquid hydrocarbons. Paraffin, petroleum oil, and marsh gas are all three substances of the same family. The symbol for the molecule of marsh gas is CH_4, or 12 parts by weight of carbon, and 4 parts by weight of hydrogen. This weight taken in grains, at the normal temperature and pressure, occupies twice 11·2 litres. Added to this CH_2, which will give C_2H_6; then add to this again CH_2, that will give C_3H_8; then, if we add another CH_2, that will be C_4H_{10}; the addition of another will make C_5H_{12}. Now, C_5H_{12} is one of the most important hydrocarbons in this ordinary petroleum oil. But there is still one more important than that, which is obtained by the addition of one more CH_2, namely C_6H_{14}. This is what is called by chemists an homologous series. To each term of it CH_2 is added, or 12 parts by weight of carbon, and 2 parts by weight of hydrogen, and it makes a new body, but still one of the same series. For some time the hydrocarbons of this class, paraffins, etc., were considered to belong to the olefiant gas series, to that gas which burns with a luminous flame, but this is disproved by their behaviour towards chlorine.

It is very important that we should know the class of compounds to which those substances belong upon which we wish to experiment for applied science. We ought to know that, because their actions on other bodies are different. Marsh gas must be heated to a white heat, in order to cause a deposit of its carbon; but olefiant gas, when heated to a red heat, gives up half its carbon, and marsh gas is formed. All these are points of considerable importance for those to understand who are going to practise upon these things for the purpose of applying their knowledge to useful purposes.

Petroleum oil, or, as some call it, rock oil, comes from various sources. It is found in America and in different parts of the world, but the same substances, or nearly the same, are obtained from coal tar and wood tar. Solid paraffin is obtained from wood tar or coal tar, or from some of these petroleum oils, by treating them in a particular way. If crude paraffin oil be distilled, a hydrocarbon comes over at 50°, probably another at 86°; there is one which comes over at 68°, the hydride of hexyl, C_6H_{14}, a principal constituent of all paraffin oils. We may go on heating it up to 280°, and get volatile matters coming off, but at last there will be a residue left, from which, if left to cool, white crystals will separate out; those are crystals of paraffin. Thus paraffin is obtained, that can be purified by subsequent treatment. For instance, it may be dissolved in hot alcohol, and, then when the alcohol gets cool, the paraffin will crystallize and deposit in scales. Then the paraffin scales, after cleansing them by pressing them with blotting paper to absorb the liquid about them, may be treated with strong sulphuric acid. If the paraffin belonged to the olefiant gas series, it would not be possible to treat it with strong sulphuric acid, because Nordhausen sulphuric acid will absorb olefiant gas; but marsh gas may be treated with a strong sulphuric acid, so that by heating the paraffin and strong sulphuric acid up to 100° C., the temperature of boiling water, and then leaving the mixture to cool, the sulphuric acid will remain at the bottom and the paraffin will come to the top, in a state of considerable purity. This is the substance of which paraffin candles are made, and it is called "paraffin," because it has no affinity for anything else; it is very difficult to oxidize or to affect in any way chemically, therefore it is called *par affine*, without any affinity. Some of these oils, as they are called, will vaporize at a low temperature, and some will vaporize as low as 4° C., namely, that represented by the formula C_4H_{10}. If a mixture of these oils, some very light and some very heavy, were heated in an ordinary lamp for burning paraffin oil, those which vaporize at a low temperature would be vaporized before the lamp is lighted. Suppose the temperature of the air to be somewhere about 18° or 19° C., all the oils that would vaporize, so that the chamber would be full of vapour and air mixed, and an explosion would follow the application of a light; for all these oils when mixed with atmospheric air produce very explosive compounds. But it is not so much the explosion that is dangerous, for it does not produce much damage usually; but what is more serious, the whole of the paraffin oil will catch fire. If ever such a calamity should happen, water should not be thrown upon it, but a mat put upon it, or anything to keep the air away from it. Paraffin lamps are now being used on railways for burning paraffin oils. Consider what would happen if a collision took place which caused the lamp to be fractured. The oil would catch fire and run down alight on the people in the carriage, and that would be a considerable addition to the calamity. It is therefore desirable that those who are engaged in promoting the use of these paraffin lamps instead of gas should turn their attention to some method to prevent a catastrophe of that kind happening. It never has happened yet, but that is no reason why it never should. The reservoir of oil is above the lamp, and if that gets broken the paraffin will have to run down in contact with the flame, and if it does so it will catch fire, and if it runs down over the passengers there would be no putting it out unless a person had the presence of mind to put something upon it to keep away the air.

The property of vaporizing possessed by these oils is very useful for some things, but very objectionable for other purposes. For burning in rooms it is best to have an oil which is heavy, and will not volatilize at any temperature to which it is likely to be submitted; but when it is wanted to apply the hydrocarbons to other purposes, such as illuminating purposes, in lieu of coal gas, or to increase the illuminating property of coal gas, then the lighter oils are better. For heating purposes the heavy oils do as well as the light ones, or rather better. Some time ago there was a scheme for making air gas by passing air through a liquid hydrocarbon in order to charge it with its vapour. It is quite certain that in its passage the liquid hydrocarbon to become vapour must take up heat from the air, must be cooled, and the cool air cannot hold in suspension so much vapour, either of water or any other liquid, as warm air can. Here, then, in passing air through hydrocarbons in order to charge it with their vapours, we have this difficulty to encounter at the first start, namely, that the vaporizing of the hydrocarbon causes absorption of heat, and therefore prevents so great a saturation of the air as might be obtained if this did not happen. But, however, we can make our hydrocarbon warm, and then we can charge air with a large quantity of it.

But suppose a gas so composed be passed through a series of mains, through a large town, when the weather is cold, the gas or air would take up a certain quantity of the hydrocarbon at a certain temperature, so as to make it fairly luminous when it was burnt; but if that hydrocarbon gets deposited by cold, as it will, then the thing must be a partial failure. When air gas was tried it did fail, and that is still the case, but that is no reason why some modification of it should not be used. Suppose there were a reservoir in each house containing some hydrocarbon, and air were forced through mains to it, and the hydrocarbon was taken up upon the premises, it might be then used, but there would still be this other difficulty to overcome, the vaporization, and some appliances would have to be added to the apparatus, in order that the hydrocarbon might be kept at a sufficient temperature to be taken up in sufficient quantity by the air passing through it, in order to get out of it the proper quantity of illumination. The lecturer said he did not despair yet of seeing this method employed.

But there is another method that is said to be doing very fairly at Chichester. Superheated steam is passed over red-hot carbon in a tube in the furnace, and a mixture of hydrogen and carbonic oxide is thus obtained, which is afterwards passed through a liquid hydrocarbon, when it takes up some of the liquid hydrocarbon, and then it will burn with a luminous flame.

If hydrogen gas be passed through petroleum oil, the petroleum oil is taken up by the hydrogen gas, and will burn with a luminous flame, which gives a large quantity of smoke. A considerable quantity of the liquid hydrocarbon is, however, deposited from the gas upon passing through a cooling medium. That experiment will illustrate what has been before said, that if the air charged with the hydrocarbon be submitted to a low temperature, a certain amount of hydrocarbon oil is sure to be deposited. If coal gas be passed through petroleum oil, on lighting it the flame is much more luminous, and deposits a very large quantity of soot on a saucer held in the flame. That is a very important point, and important results might be got from studying this action. In the first case we have gas containing carbon, hydrogen, carbonic oxide, and olefiant gas—that is, coal gas. That passes through the tube, and burns with a luminous flame. When we add to it a hydrocarbon it takes up some of the hydrocarbon in suspension, and the flame becomes more luminous and smoky, showing there is a very large quantity of carbon in the material burnt, which carbon cannot be fully burnt, or anything like fully burnt. But directly there is a greater supply of air introduced, as in the Bunsen burner, there is a more perfect combustion of the carbon of the coal gas, and of the carbon of the hydrocarbon with which the coal gas was charged. Experiments were performed some time ago with hydrocarbons for the purpose of making coal gas more luminous, but they so far failed that the material has never been brought into general use. But there is a very large field for inventors to work upon, in giving greater luminosity to coal gas.

Another point is, that if a certain quantity of the carbon and hydrogen of coal gas burn for a certain space of time, the carbon and hydrogen in burning must give out a certain amount of heat, and no more; and if more carbon be put to it, and more hydrogen, then that carbon and that hydrogen which is burnt must give out an additional quantity of heat. The Silber lamps and Mr. Dietz's lamps are very successful and good lamps, so far as the light goes, but they are excessively hot; there is an enormous amount of heat given out in the combustion, because the hydrocarbon oils are very rich in carbon. So with those fires that are arranged with lumps of asbestos, or fireclay. You turn on the gas and have a fire in a very short time; it is a very convenient and very agreeable substitute for, though it is not so good as, an ordinary fire; but they have certain merits. In these coal gas is burnt, and it would be well for those connected with the manufacture of these fireplaces to turn their attention to this fact, that the proportion of air and coal gas in most of those stoves is not properly regulated, for upon the lumps of asbestos a considerable deposit of unburnt carbon is formed. This ought not to be. A certain amount of heat is lost by the deposit of carbon on the fireclay. If the coal gas were passed, prior to its being burnt, through some of these liquid hydrocarbons heated in a vessel at the side, and projected upon the fireclay, and if it were properly apportioned to the quantity of atmospheric air allowed to pass in with it, a very high heating power would be obtained, and the advantage of it would be that the heat would be stored up in the fireclay, and would then be given out again into the room gradually. Experiment has proved that by adding hydrocarbons you do not intensify the heat of the flame at any given moment. Yet in the combustion of the coal gas, together with the hydrocarbon, you do produce a larger amount of heat, and if the heat be stored up in such a reservoir as lumps of fireclay, that heat is given out in the room, and a very economical use of fuel effected. In nearly all these experiments the mistake is that a sufficient quantity of air is not projected along with the hydrocarbon. People allow the natural draught to do it, but the natural draught is not always sufficient, therefore some kind of blowers should be used. Again, if the air be sent in cold its effect will not be nearly so great as if the air be sent in at a higher temperature, so that when it comes into contact with the hydrocarbons it will be at a temperature somewhat approaching that at which they are burning.

A word or two about the luminosity of flame. The flame of hydrogen gives no light, but directly a hydrocarbon is added to it it gives light, but the flame is very smoky. If we examine the flame of a candle carefully we shall find the yellow portion of the centre, with the little blue portion below, and if we look very carefully we shall see a sort of halo all around, which can hardly be called luminous, but is a flickering sort of halo; that halo is where the most perfect combustion in the flame of carbon takes place. In the centre of the flame there is imperfect combustion of the carbon, and the carbon gets set free. The carbon which is set free in the centre of the flame (from the marsh gas it may be, or most certainly from the olefiant gas, and from the hydrocarbons in the gas), that carbon in a state of very fine division becomes incandescent, and so gives light. The oxyhydrogen light does not give much light; but if a piece of lime be put into it we get a brilliant light, because the lime becomes incandescent. If we take a piece of iron it gives no light, but if we put it into the fire and heat it to a white heat it gives a light. The presence of solid matter therefore appears to be essential to the light-giving properties of our ordinary illuminating flames. There have been experiments performed by Professor Frankland, from which he says that the presence of solid matter is not absolutely essential, but probably neither he nor any one else would at all doubt the fact that the luminosity of ordinary flames is owing to the presence of solid particles heated to incandescence. What we want to do to make our flames give a proper light, and to economize our fuel to the fullest extent, is to add a proper portion of the oxygen of the air to the quantity of the hydrocarbon being burnt.

Coal is not the only source from which we can obtain a luminous gas. We can obtain it from any animal or vegetable substance. Any organic substance containing carbon and hydrogen, when heated out of contact with atmospheric air, will give off a gas similar to coal gas.

From whatever source we get gas its main constituents are the same. Coal gas contains certain gases which are useful for illuminating purposes, and also certain gases which are not useful, but, on the contrary, hinder the illuminating power of those which should give light, or contribute to give light. First of all, coal gas contains hydrogen; it also contains marsh gas, olefiant gas, and carbonic oxide gas. All these four gases are useful for illuminating purposes. Hydrogen by itself gives no light, and carbonic oxide gives no light, and marsh gas gives no light, but olefiant gas gives a light, owing to its containing a large quantity of carbon. Of what use, then, are those other three gases? One use is that they hold in suspension the hydrocarbons, for coal gas, if it has good illuminating power, especially that which is made from cannel coal, contains a very large quantity of hydrocarbons. It contains a hydrocarbon called butylene, and also napthaline, a solid hydrocarbon, and other hydrocarbons. Coal gas will take up hydrocarbons in small quantity, and keep them in suspension in spite of any freezing mixture through which it might pass. And these hydrocarbons assist in giving light. Gases that take them up in suspension assist in giving heat, for the carbonic oxide and the marsh gas flame and the hydrogen flame are all very hot, and they also decompose the hydrocarbons and deposit the carbon in the flame, and the carbon becoming incandescent gives light. Then there are certain impurities in coal gas, impurities which do not exist in gases made from such substances as oil. One of the greatest impurities in coal gas is sulphuretted hydrogen. Some of the hydrogen of the coal unites with carbon to form marsh gas, and with some of the carbon to form olefiant gas, and some of the oxygen and carbon to form carbonic oxide, and some of the hydrogen unites with the sulphur and forms sulphuretted hydrogen, and some sulphur unites with some of the carbon to form a liquid called bisulphide of carbon. The impurities, then, in coal gas are very numerous, and among them is ammonia.

Parliamentary and Law Proceedings.

Alleged Adulteration of Spirits.

At the Borough Police Court, Hanley, Wm. Jackson, manager of the Sea Lion Hotel Vaults, has been charged with having sold to one John Bamford, one of the borough food inspectors, a pint of whisky, which was adulterated in such a manner as to be injurious to health. Mr. Bamford stated that he purchased the whisky in question on the 13th of September, after telling the manager of the vaults, Mr. Jackson, that it was for analysis. The analyst's certificate was handed in, which stated that the sample in question was adulterated with wood spirit, methylated spirit, and also bore traces of lead, which made it injurious to health. Bamford was severely cross-examined, with a view to showing that a considerable time had elapsed between the time of receiving the sample and forwarding it to the analyst, and that in the meantime it might have been tampered with. The Bench held the objection as to the irregularity in not declaring the liquor bought for purposes of analysis fatal to a conviction, and dismissed the case.

Thomas Knot, landlord of the Royal Oak Inn, Stafford Street, was then charged with selling, as pure, a pint of gin, which the certificate of the county analyst stated was adulterated with water, impure spirit, and bore traces of lead, and was so adulterated as to be injurious to health. The objection in the former case was held to be fatal in this one, and defendant was discharged.

There where four other charges of adulterations against publicans, but after the above decisions the informations were withdrawn.—*Brewers' Guardian.*

Action by an Advertising Agent.

In the Court of Exchequer, at Westminster, on Tuesday, November 10, before Baron Pollock and a common jury, there was tried the case of Crook *v.* Steele, an action for breach of contract brought by Messrs. Crook and Co., advertising agents at Brompton, against Messrs. Steele and Marsh, chemists, of Bath. The plaintiffs sent one of their circulars to the defendants, asking for authority to advertise in a series of almanacs and directories certain vegetable pills. After some correspondence the defendants assented to the advertisements being put into 200 of these various almanacs aud directories, a list of which had been furnished by the plaintiffs. The agreement was to take half the amount of payment in goods and the other in cash; and the declaration alleged that the defendants had committed a breach of that agreement by refusing to give either goods or cash. The defendants denied that allegation, and said that the advertisement had not been put into the number of publications agreed upon, pleading never indebted. Mr. Palmer appeared as counsel for the plaintiffs, and Mr. Huddlestone, Q.C., for the defendants. In the course of the examination of the plaintiff Crook, the learned Judge took exception to the alleged contract being on unstamped paper, that objection being fatal to the case unless the plaintiff consented to pay the penalty. The learned Judge suggested to the plaintiff Crook and his counsel the propriety of considering whether he should pay the penalty or not under the circumstances. After some consultation with his client, the counsel for the plaintiff consented to a nonsuit.

Poisoned by a Medicine.

The *Lancet* says, an accident that recently occurred at St. Bartholomew's Hospital affords another illustration of the impropriety and the danger of leaving poisonous drugs, or, in fact, medicines of any kind, so exposed in the wards that patients may help themselves. In several of the metropolitan hospitals the medicines of the patients are left on a locker at the side of the bed, or are placed on the table in the centre of the ward. As a rule, no trouble or inconvenience arises from this practice, but the consequences may be serious if a delirious or an anxious patient should take an overdose of medicine of a poisonous nature. Still more objectionable than this practice of allowing medicines to lie about is that of leaving poisons, strong acids, and chemical tests on open shelves, especially when the bottles containing them are promiscuously mixed up with those containing lotions, liniments, and house medicines for the use of the patients. Poisonous liquids should not only be placed in specially prepared bottles, but they should be put in a secure place apart from the medicines of the patients. The hospital authorities cannot too speedily attend to this question, and so arrange matters that accidents cannot occur except from gross carelessness and neglect.

Sudden Death of a Chemist and Druggist.

Shortly after one o'clock, on Sunday afternoon last, Mr. Thomas Mittchell, chemist and druggist, was found dead in his bed, at his residence in West Street, Gravesend, Kent. The cause of death is stated to have been apoplexy.

Obituary.

DR. F. ROCHLEDER.

In Vienna, on the 5th of this month, died Dr. Frederick Rochleder, the successor of Redtenbacher in the University Chair of Chemistry. The deceased *savant* was one of the most successful teachers in the school, and enjoyed among his colleagues a distinguished reputation for his numerous contributions to science. Rochleder was the son of a Vienna apothecary, and was born in 1819. There he completed his studies, and graduated as Doctor of Medicine in his twenty-third year. While still a student he was an ardent lover of chemistry, working diligently in the laboratory of Redtenbacher, the then assistant to the Chemical Professor in Vienna. At the same time Liebig was making the little university town of Giessen a centre of attraction to all young chemical aspirants throughout the world, and in 1842 Rochleder was swept into the stream. After three years' zealous study under the great teacher he was appointed Professor of Chemistry in the technical academy at Lemberg, and such was the popularity of his lectures that there was barely standing room for his audience. In 1849, on the removal of Redtenbacher from Prague to Vienna, Rochleder succeeded him in the Bohemian School, where he worked indefatigably for twenty-one years, till Redtenbacher's death, in 1870, summoned him to the Chemical Chair in Vienna. In the laboratory recently erected beside the Chamber of Deputies, Rochleder drew around him enthusiastic auditors of his lectures and eye-witnesses of his experiments; and such were his energy and devotedness that his constitution gave way, all too early for science and for the Vienna School. He died, as already stated, on the 5th inst., and was followed to the grave on the 7th by a long train of sorrowing friends and pupils. Phyto-chemistry was his favourite department, in the science of which he was so accomplished a master, and formed the subject of two elaborate treatises from his pen, published in Vienna and Leipzig respectively in 1847 and 1854. His researches in aromatics and similar articles of luxury, in the chemistry and physiology of plants, his contributions to Liebig's 'Annalen,' and his papers in the 'Transactions' of the Imperial Academy of Sciences are so many proofs of his acute intellect and unwearied industry. In 1848 he was elected a Fellow of the Academy, a Member of the Bohemian Association of Sciences at Prague, of the Frankfort Physical Society, and of the Imperial Association of Naturalists at Moscow. Rochleder was, we may add, something more than a *savant:* he was an active and philanthropic citizen, inheriting the virtues of the good old apothecary, his father, and the suavity of demeanour and address of his greatly admired mother. His loss will long continue to be felt in the Kaiser city, of which he was at once a brilliant ornament and an able support.

DR. EDWARD SMITH, F.R.S.

The death has been announced of Dr. Edward Smith, F.R.S., Assistant Medical Officer to the Local Government Board. Dr. Smith had acquired a considerable reputation as the author of various treatises on subjects connected with food and sanitation. Perhaps that which attracted the widest attention was a paper read before the British Association at Brighton, in which he disputed the alleged virtues of extract of meat, in such a manner as to call forth a reply from the late Baron Liebig. The discussion was continued in the daily papers, and the latest communication from Baron Liebig on the subject was published a short time before his death in these columns. Since that time, a work by Dr. Smith, on "Foods," has been published, which has reached a third edition; also a "Manual for Medical Officers of Health," and a "Handbook for Inspectors of Nuisances."

Dr. Smith held the degrees of M.D. (1843), and LL.B., and B.A. (1848) of the University of London. He was also a corresponding member of the Natural History Society of Montreal and of the Académie des Sciences et Lettres de Montpellier.

Notice has been received of the death of the following:—

On the 23rd October, 1874, Mr. Henry James Woolley, Chemist and Druggist, of Ross, Hereford.

Reviews.

The Specific Action of Drugs on the Healthy System: An Index to their Therapeutic Value, as Deduced from Experiments on Man and Animals. By Alexander G. Burness, M.B., C.M. Univ. Aberd., and F. J. Mavor, M.R.C.V.S. London. 1874.

"To point out to their conjoint work that the full therapeutic value of each substance—its value in the treatment of disease—is only to be determined by ascertaining the symptoms produced and the parts influenced by each substance when introduced into the healthy animal economy; and that this is to be done by careful observation of cases when a substance has been introduced either by accident or intention, the quantity taken in each case, as well as the form and mode in which introduced, being also noted"—such, say Messrs. Burness and Mavor in the preface, is the object of the treatise before us.

The first three chapters are mainly theoretical. Every disease is shown to have certain primary, yet peculiar, symptoms, caused, in the majority of cases, by some unknown agency affecting specific tracts or viscera in a specific manner; while there are also shown to be certain known agents exerting a primary influence on certain parts, and producing symptoms peculiar to each when introduced into the healthy body. Chapter 2 indicates that the specific action of each substance thus obtained is the key to its therapeutic value—to its physiological action on the one hand, and to its restorative action on the other; while the third chapter treats of the form and mode of administering substances with a therapeutic object. A few remarks in chapter 4 on temperature in health and disease conduct us to the really practical portion of the work—that on the specific action of drugs. All non-nutrient agents, Messrs. Burness and Mavor contend, pass out by one or other of the eliminating tracts, *en route*, by their physical, chemical, or dynamical properties.

In all this there is little or nothing to object to, except that it is not very new, and is introduced with a pomp of diction justifiable, if at all, only by the announcement of a novel and startling discovery.

The hypodermic administration of drugs, the authors maintain (incommon, we may add, with every intelligent practitioner), has the advantage, especially in acute disease attended with pain, of producing a rapid physiological effect, without deranging the digestive organs or exposing the drug to alteration by the digestive fluids. Morphia, atropine, strychnia, aconitine, quinine, so administered, are most certain and most readily efficacious. The case mentioned by Mr. Surgeon-Major O'Leary, of the Indian army, in which a man, moribund from sunstroke, revived after quinine hypodermically administered, is one not mentioned by Messrs. Burness and Mavor, but highly confirmatory of their doctrine.

By way of antidote to poisonous drugs, hypodermic introduction of remedies is also more rapid and more certain than exhibition through the stomach. Take, for instance, morphia, and its counter-agent strychnia. Half a grain of acetate was given by Messrs. Burness and Mavor to a dog, and in two hours the full physiological effect of the drug having been obtained, $\frac{1}{16}$ of a grain of strychnia was administered, and in forty minutes the dog had quite recovered. This counteraction of morphia by strychnia, and *vice versâ*, was exemplified in repeated experiments by the authors, the hypodermic mode of administration being convincingly proved to be the best in all respects.

The volume is of as much veterinary as medical interest, a fact which must absolve us from entering more fully into the experiments described in it. Even in this department it can be justly characterized as only a contribution to the better understanding of drugs and their action. We expect higher things from Dr. Brunton's promised treatise, more rigid, as he undoubtedly is, in his scientific training, and more cognizant of the later German and Italian research. On the whole, however, Messrs. Burness and Mavor have worked honestly and intelligently, and their work will repay perusal, if not always for established fact at least for suggestive theorizing.

The Forest Flora of North-West and Central India; a Handbook of the Indigenous Trees and Shrubs of those Countries. By J. Lindsay Stewart, M.D., and Dietrich Brandis, Ph.D. London: W. H. Allen and Co.

This is a book of 608 pages of closely printed valuable matter, published by authority of the Indian Government. It is, in short, a type of what all our colonial Floras ought to be, for the botanical descriptions are concise, the details of distribution are full, the vernacular names are likewise fully given, and the uses of the plants are comprehensive. Though the book is essentially a *Forest Flora*, and its object, as Dr. Brandis says in his preface, "entirely practical," being intended as a handbook "to enable forest officers to acquire a knowledge of the trees and shrubs in the forests, and of the climbers, epiphytes, and other plants which impede and injure the growth of trees," it is, nevertheless, a book that should be equally as much in the hands of those interested in Indian vegetable products who stay at home as those actually resident in the country itself, though to the latter, especially those in the forest service, the book will be invaluable.

Though the title at a first glance seems to disqualify the book for a notice in our pages, we are sure no apology is needed for introducing it here, for it treats of forest produce in the widest sense. In view of objections being taken to the plan of the book or of its bulk, Dr. Brandis says: "Such objections will be supported by those who hold that the sole legitimate duty of forestry in India is to provide fuel and timber, and that the forester has no concern with bark, lac, gums, resins, caoutchouc, wax, oil, dyes, fruits, and other marketable products of trees and shrubs. Such views will continue to be maintained until it comes to be acknowledged that the principal aim and object of forest management in India is the formation of public estates, to be managed so as to secure large benefits to the country of an indirect nature, as well as a continuous and increasing yield of all descriptions of forest produce necessary to supply the requirements of the people and their export trade."

With regard to the plan of the book, it is almost identical with that of the colonial Floras which have been issued of late years from Kew, but with the addition, as we have before said, of a great deal of reliable information on the uses and distribution of each species.

An example will illustrate better the nature of the book than any description of our own. Thus, under the genus *Tamarindus*, we find a generic description of the Tamarind (*T. indica*, L.), followed by references to botanical works in which it has been described, then the vernacular names, and a short specific description; after which we read that it is—

"Cultivated throughout India and Burmah, save in the North-Western Punjab; trees are found as far as the Jhelam, but the fruit does not ripen West of Amballa. In the Central Provinces, the Bassi forests of Meywar, and in many parts of South India the tree is found self-sown in waste and forest lands, but there seems no sufficient evidence of its being originally indigenous to India. Wherever I have seen it it has been in the vicinity of existing or abandoned cultivation. The tree is cultivated in the tropics of both the new and old world, and is believed to be truly indigenous in tropical Africa (Oliver, *Fl. Trop. Afr.*, ii., 308). Never leafless, the foliage changes in March and April; fl. May, June; fruit ripens 7-9 months after flowering.

"A large tree, attaining 80 feet or more, with a short thick trunk (25 feet girth not rare), often ridged, with a magnificent, broad, and high, shady crown. Bark ½ inch thick, dark grey, brownish to blackish, tesselated by longitudinal fissures and cross cracks. Wood yellowish white, hard and close grained, the outer and younger wood a little softer, but the sapwood not defined by a concentric line, such as we find in the wood of teak, sissoo, sal, bija sal, oak, and other trees. Heartwood small near the centre, outline very irregular, dark purplish brown, projecting into the yellowish outer wood, with radiating ramifications, so that planks frequently show alternate layers of light and dark coloured wood. Annual rings indistinct, medullary rays very numerous, very fine, pores moderate, equal, uniformly distributed, each pore or group of pores surrounded by lighter coloured tissue. . . . . Polishes well, and, though extremely hard and difficult to work, is highly prized for many purposes when a tree past fruit-bearing is felled. Naves and other parts of wheels, mallets, planes, tent-pegs, furniture, rice pestles, oil-presses, and sugar-crushers are made of it; it is an excellent wood for turning. The heartwood is very durable. The outer wood is apt to be eaten by insects.

"Mainly cultivated on account of the acid pulp of the pod; there are several kinds, with sour, sweetish, and red pulp. The pulp contains citric, malic, and tartaric acid; large quantities are imported into England from the West Indies. It is officinal as a laxative and refrigerant (Pharm. Ind., 64). The seeds (*Chincha*) are used in native medicine; pounded, they are eaten in times of scarcity, and the powder mixed with gum makes cement."

At first sight of the book, it would appear that the *Forest Flora* was scarcely up to time in the identification of species furnishing medicinal and other products, the result of recent investigations, for almost at the commencement we find *Cissampelos Pareira* described as producing the *Radix Pareiræ* of the druggists, but this is fully compensated for in the "additions and corrections," where we read that "the botanical origin of the various stems and roots known as *Pareira Brava* and *Radix Pareiræ* has lately been investigated by Mr. D. Hanbury (*Pharm. Journ.*, 1873, Aug. 2nd and 9th). The result is that the drug is not yielded by this plant (Cissampelos). One of the best kinds is the root of *Chondodendron iomentosum*, Ruiz and Pavon, a large climber of the same family in Brazil, with bunches of large oval berries." In the same way, with regard to the species of *Boswellia* furnishing olibanum, which is used both medically and in incense in India, and is sold in the bazaars, in the body of the book, under "Burseraceæ," it is referred to *Boswellia thurifera*, of Colebrooke, but in the "additions and corrections," it is stated that "the correct name of this common and well-known tree has not yet been finally settled," and Dr. Brandis gives an outline history of its nomenclature. In the first reference (p. 62) he states that the Olibanum furnished by the tree is not identical with the "Olibanum, or frankincense, chiefly used in Europe, which is yielded by several other species of Boswellia, growing in the Somali country and on the Hadramaut hills, in Arabia, and described by Dr. Birdwood, in 'Trans. Linn. Soc.,' xxvii., III."

The book is splendidly illustrated by a separate volume of seventy quarto plates, faithful representations of the principal species referred to in the book, all of which have been drawn by Mr. W. H. Fitch, whose name is a sufficient guarantee for their accuracy.

Notes and Queries.

EFFECTS OF AMMONIA ON THE COLOUR OF FLOWERS.—Professor Gabba has been examining the effects of ammonia on the colour of flowers. It is well known that the smoke of tobacco will, when applied in sufficient quantity, change the tint of flowers; but Professor Gabba's experiments consist in pouring a little ammonia liquor into a saucer, and inverting a funnel over it. Placing the flowers in the tube of the latter, he finds that blue, violet, and purple-coloured blossoms become of a fine green; carmine and crimson become black; white, yellow; while parti-coloured flowers, such as red and white, are changed to green and yellow. If the flowers are immersed in water the natural colour will return in a few hours. Professor Gabba also found that asters acquire a pleasing odour when submitted to the fumes of ammonia. —*Garden.*

THE APPOINTMENT OF EXAMINERS.

Sir,—It was with very mixed feelings that I read the report of the discussion at the last Council meeting upon the election of examiners. All members of the trade will agree that such elections are of the highest importance, exercising as they necessarily do an incalculable influence upon our status. Hence it appears to me that whilst we may congratulate ourselves upon the fact that our councillors are awake to the necessity of keeping up the efficiency of the Board, there is cause for regret that they do not propose to adopt a course which would fully ensure it.

In the first place, it is essential that the Board should at all times command the respect of all students, and, indeed, of the trade at large. Can this be attained without giving a certain degree of stability to the Board, and to this stability is not the proposed ballot most inimical? To me it appears derogatory that a gentleman who has been called upon to perform such important duties should have to submit to an annual ballot.

I would suggest that the examiners be elected for a period of five years, except at the outset, and that three should retire annually by rotation, but be eligible for re-election.

Further, it would be well to get rid of the idea of "candidateship" for the office. This could be done if the members of the Council would look around, and having selected a certain number that they, as a body, considered eligible, to obtain from such gentlemen permission to choose (not elect by ballot) from them and the retiring examiners the three required to fill up the Board.

I am aware that there is little novelty in the last part of the scheme, but I attach some importance to the primary selection being an act of the Council collectively.

We should then have our examiners chosen in such a way as to exclude any idea of favouritism, and the fact of their election being for a specified term would give them that degree of independence which is necessary to render their position complete.

To those who say with Mr. Greenish that an examiner too rapidly falls into a groove, I would reply with Mr. Schacht, "that the duty of examining involves duties which are learned by experience."

E. NUTHALL.

Bank Plain, Norwich, November 17, 1874.

PHARMACEUTICAL EDUCATION.

Sir,—Reading Mr. A. R. Willron's communication in your impression of the 7th inst., I am constrained to ask permission to encroach upon your valuable space, and endeavour to console his injured feelings.

Well may he inquire what the poor unlucky Associates have done to be so unceremoniously recommended to become grocers. But, although I am an Associate myself, I cannot say I altogether differ from Mr. Proctor. He evidently means to show that if you remain an Associate, you are obliged to countenance those cheats, or whatever else you have a mind to designate them, who have managed to win the prize without the labour of the race; as not a few most undoubtedly do, to whom he reverts in a former part of his letter.

In my opinion, a man, if he worked conscientiously, would not rest until he had surmounted all obstacles, even to the passing of the Major examination, which too many unfortunately regard as an expensive, unnecessary, and unremunerative distinction.

It will be asked, how if you cannot afford the expense? I will only answer by directing their attention to Mr. Proctor's advice to "turn grocer," or some trade where there is not so much outlay required. In setting up for oneself, one surely ought to be able to spare the sum necessary for the Major, and I dont think Mr. P. means to urge the absolute necessity of passing it until about to enter business on one's own account. The only remedy I can see to reducing the detestable practice of cramming is to make the Major also compulsory, and I trust the day is not far distant when the step will be taken. It must come to it in time. I am sure there is no lack of men ready and willing to endorse what I have said, but at the same time there are but too many who will cry with indignation against it, as another unjust and dishonest means to improve our position. But I would beg them to remember that a serious disease requires severe remedies, and it is generally the most effectual medicines which are the most unpalatable.

Nor do I quite understand your correspondent from Truro, who declares that the "nefarious policy of educational demands" is instituted in order to cut off men from an accustomed mode of subsistence.

I think it is a matter rather to be regretted that some of those "educated men of mature age and sound judgment," of whom he speaks, did not take the opportunity of pointing out to our legislators, when about to pass the Pharmacy Acts for the better protection of the public against accidents, arising from ignorant men dealing in poisonous substances, what a measure *contra salutem publicam* it was.

I confess that if the letters in your impression of the 7th indicate the feeling of chemists in general on the important subject of pharmaceutical education, I don't exactly see how they can expect their trade to rank as an "art," and more especially as a "science," as Mr. Willron seems to be under the impression it is.

They might remind one of a weathercock, which at one gust of wind unite in crying for an improved position of the trade, while the next sends them flying round for the desirability of admitting all the dunces who cannot pass such a simple test as the Preliminary or Minor examination. I should only assure them in conclusion that if they were to secure the admittance of the much-to-be-pitied unsuccessful candidate without the trouble of an examination, I am rather afraid they would have to abandon their high-flown aspiration of ranking as a profession.

M. C. ATKINSON.

Queen's College, Galway, Ireland, November 15, 1874.

CALAMINE.

Sir,—The note which you appended to my communication upon calamine powder has puzzled me, in common with many others, very much. Firstly, you refer to "a note" by Mr. Reynolds, written five years ago, and remark that "the defect pointed out by Dr. Fox arises from the nature of the material used," whereas I lay the greatest stress upon the mode of preparation of the calamine powder. Secondly, you add "probably (!) the physician's object would be best obtained by using an artificial (!) carbonate of zinc, with just enough red oxide of iron to give it the correct tint;" whereas I emphatically state that "the colour should not be artificially mixed," and "that calamine powder should be real calamine powder."

I ask for true calamine powder, and you offer me an artificial preparation—a "stone" for a "fish." You will not be surprised that I decline to accept it.

TILBURY FOX.

November 18, 1874.

[*** As Dr. Fox declines to accept our suggestion that the use of artificially prepared carbonate of zinc, with just enough "red oxide of iron" to give it the correct tint, would probably be the best means of attaining the physician's object when he prescribes calamine, and since he declares that he is "puzzled" by this, we may explain that our suggestion was instigated by Dr. Fox's statement that Mr. Martindale had sufficiently explained the special reason for the use of calamine together with oxide of zinc. If that explanation be sufficient, this use of calamine would appear to belong more to the cosmetic art than to therapeutics. In that case, since the grey, green, or brown colour of calamine is due to the admixture of carbonates of iron, manganese, etc., in accidental proportions, we should be disposed to consider it a somewhat barbaric article of materia medica, and should incline to the opinion that a pure carbonate of zinc, appropriately coloured, would be preferable to a material of such variable composition, colour, and texture as native calamine, and it would, we believe, be more likely to possess the characters which Dr. Fox regards as desiderata.—ED. PH. JOURN.]

GLYCERINE JELLY.

Sir,—I notice in your Notes and Queries an inquiry respecting glycerine jelly, I presume from a student. The formula given in answer to the inquiry I believe would not be found satisfactory, and students generally have not time to spare to be floundering about in making unsuccessful trials in a matter of this kind, and having great sympathy with those who try, but for lack of help don't succeed, I have much pleasure in sending to the Curator of our Museum one dozen bottles of glycerine jelly, and half a dozen dammar varnish, for the use and benefit of such students connected with the Society as may require either one or the other.

For all fresh vegetable or mineral tissues no medium is so good or so convenient. The dammar varnish is used for either fixing the covers or as a medium for mounting, instead of balsam.

THOS. RIMMINGTON.

November 9, 1874.

[*** Our correspondent is correct in saying that the formula as it stands on p. 379 might not give a satisfactory result, as directions for the clarifying of the gelatine by means of albumen were accidentally omitted. With this addition, we are informed the recipe is a very good one. See also an article on the subject by Mr. Pocklington, at p. 401 of the present number.]

EARLY CLOSING MOVEMENT.

Sir,—As the subject of early closing is again brought before our notice, I, as an employer, hope and trust that all the chemists will now unite and endeavour to shorten the hours of business. I am ashamed to say in this neighbourhood we do not close until 11 p.m. About three weeks since a gentleman of known repute undertook to call upon all the chemists in his immediate district, and, as a result, one and all agreed to close at 10 p.m. That movement, I am sorry to say, only lasted a fortnight, one of the number (one black sheep in every flock) withdrawing, his excuse being too simple to mention. I am convinced that earlier closing would be a step in the right direction; it would tend to give our young men time for study and recreation, and to throw off that odium which now exists; and it would shorten the mental anxieties as well as the physical labour of business. I trust one and all will join in promoting the cause.

CURA UT VALEAS.

London, November 16, 1874.

"DISSATISFIED YOUNG MEN."

Sir,—Permit me the use of your columns to inform those gentlemen who are so fond of writing to you about the long hours, the small remuneration, and other *désagrémens* incidental to the drug business, which I fear are inseparable from the practice of pharmacy, that the Rev. Dr. M'Auslane, the pastor of the Finsbury Chapel, preached on Sunday evening last a special sermon—one of a series—on the subject of "Dissatisfied Young Men." It is probable that many among us would like to hear the concluding discourses, and for the benefit of those who were not able to be present at the opening lecture, I would mention what the Rev. Doctor said:—

"The question as to what was true satisfaction was answered by the Apostle when he said, 'I have learned in whatsoever state I am, therewith to be content.' Of all who ought to be most satisfied were the young men who lived in the great metropolis of the empire. They had health and strength, vigour and elasticity, were buoyant with hope, with few cares, burdens, or trials. Yet a great number of them were as restless as the ocean. They were dissatisfied with their homes, their situations, their friends, their country, and, worst of all, with themselves. This was a terrible evil, and would continue to grow unless they struck at the very root from which it sprang, and removed it."

As a chemist who has been in business for himself twenty years, I myself am too apt to compare my profession unfavourably with that of others, and when it is my "Sunday evening out" I think I shall wend my way to Finsbury Chapel, and try and get a little comfort from Dr. M'Auslane.

Dissatisfaction with one's calling in life is a very old complaint. Horace well notes it when he says—

> "Qui fit Mæcenas, ut nemo, quam sibi sortem
> Seu Ratio dederit, seu Fors objecerit, illa
> Contentus vivat, laudet diversa sequentes."

"A DISSATISFIED MASTER."

London, November 17, 1874.

H. Hyne.—We were aware that Ung. Plumbi Carb. is sometimes supplied when "unguentum" is asked for, but did not think the custom sufficiently general or commendable to recommend you to follow it.

"*Another Examined Assistant.*"—Our correspondent was referring to the utilization of unoccupied time, but, according to your description, that is a commodity with which you were not troubled at the place you mention. The two grievances entirely differ, and we prefer to limit the discussion at present to the former, as being the more pertinent to pharmacy. Surely a little energy on your part would, in less than two years, have put you into a better position than one where, after being fifteen hours behind the counter, you were required to fill up the remainder of the evening in "rolling a few pills."

W. E. Smithies.—You are recommended to consult your solicitor on the point. We do not think the practice of prescribing over the counter is one that should be countenanced by pharmacists in any way.

J. Horncastle.—We are obliged to you for your communication. The paragraph had been already marked by us for insertion. We shall take an early opportunity of giving a résumé of Kolbe's paper.

S. Wylde.—The first form is correct, but the second is perhaps more commonly used. The latter requires, however, some phrase to be understood which shall become the direct object of the transive verb.

B. P.—(1) We think not. (2) We can give you no better answer than to repeat the sentence in the examiners' regulations which raises your doubt. (3) Yes.

T. C. B. K.—We know of no book treating of the subject, and it is one of which a knowledge can only be acquired practically.

A Dispenser.—The slight taste of the salt may easily be covered by means of a little bitter infusion—gentian, for instance.

D. H.—Simple solutions of the respective colours.

J. A. Butler.—In using soda as a precipitant it is more difficult to remove the alkali.

F. O. B. Marchant.—According to the Preface to the British Pharmacopœia, the avoirdupois ounce would be implied, though it is just possible the apothecaries' might be intended.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Hayes, Mr. G. M. Smith, Mr. Pitman, J. F.

NEW METHOD OF PREPARING SALICYLIC ACID, AND ITS PHYSIOLOGICAL ACTION.*

BY PROFESSOR KOLBE.

Artificial oil of gaultheria, in which the percentage of salicylic methyl ether is very variable, is too costly for the preparation from it of any considerable quantity of salicylic acid. Professor Kolbe experimented, therefore, whether a method formerly described by Lautemann and himself, for the preparation of artificial salicylic acid ($C_7H_6O_3$) from carbolic acid by the joint action and carbonic anhydride and sodium, could be simplified and improved so as to allow of salicylic acid being obtained at a more reasonable cost. This object he has succeeded in attaining. After numerous experiments, Professor Kolbe finally adopted the following method:—In a strong crude soda-liquor of known strength is dissolved a sufficiency of previously melted crystals of carbolic acid to saturate the caustic soda. The solution is then evaporated in an iron capsule, and by means of stirring brought to a dry powder. The sodium carbolate so obtained is gradually heated in a retort to a temperature of from 220° to 250° C. in a continuous current of dry carbonic anhydride. The reaction is ended when at the above-mentioned temperature no more carbolic acid passes over. It might have been expected that, the reaction going forward in this manner, a molecule of carbonic anhydride would be introduced into the molecule of sodium carbolate, and thus a molecule of sodium salicylate be formed:—

$$C_6H_5O\,Na + CO_2 = C_6H_5O\,COO\,Na.$$

This, however, is not the case, only half the sodium carbolate being converted into salicylate. The reaction proceeds according to the following equation:—

$$\begin{matrix} C_6H_5ONa \\ C_6H_5ONa \end{matrix} + CO_2 = C_6H_5ONa\,COO\,Na + C_6H_5OH.$$

In two molecules of sodium carbolate under the influence of carbonic anhydride an interchange of H and Na takes place, so that on the one hand carbolic acid, and, on the other side, disodic carbolate result, which latter then combines with the carbonic anhydride to form disodic salicylate.

$$C_6H_5ONa + C_6H_5ONa = C_6H_4NaONa + C_6H_5OH$$
$$C_6H_4NaONa + CO_2 = C_6H_4ONa\,COO\,Na.$$

From this salt the salicylic acid is separated by means of hydrochloric acid.

The special physical and chemical properties of salicylic acid are well known, but its physiological action almost not at all. The knowledge that salicylic acid could be so easily prepared from carbolic acid and carbonic anhydride, and that it could be again decomposed by heat into the same bodies, led Professor Kolbe to think that, similarly to carbolic acid, salicylic acid might stop or entirely prevent fermentative and putrefactive processes, and operate generally as an antiseptic. This expectation has been confirmed. Mustard meal, which, in a few minutes after being mixed with warm water gave off a strong smell of mustard oil, formed with water a scentless mixture when a little salicylic acid had been previously added. No fermentation was set up by yeast in a solution of grape sugar to which salicylic acid had been added; whilst in a sugar solution already in fermentation the action stopped after the addition of some salicylic acid. The preservative influence of this acid upon fresh meat is referred to on another page.

The following, among other experiments, in their results illustrate the physiological action of salicylic acid:*—

Solution of amygdalin mixed with emulsion of sweet almonds developed no smell of bitter almonds if some salicylic acid were added.

Beer, to which salicylic acid in the proportion of 1 in 1000 was added, was thereby prevented from being spoiled by fungoid growth.

Fresh pure cow's milk mixed with 0·04 per cent. of salicylic acid, and allowed to stand in an open vessel at a temperature of 18° C., curdled thirty-six hours later than a similar quantity of milk standing by the side of it, but containing no salicylic acid. The milk remained of a good flavour, the small quantity of salicylic acid present not being perceptible to the palate.

Some fresh urine was divided into two portions and placed in separate vessels, after some salicylic acid had been added to one portion. The urine containing the acid was on the third day still clear and free from ammoniacal odour, whilst the other portion was far advanced in putrefaction.

Professor Thiersch has investigated the antiseptic action of this acid specially in relation to surgery. He has found that as a powder, either alone or mixed with starch, it destroys for a long time the fetid odour of cancerous surfaces or uncleansed wounds, without setting up any inflammatory symptoms. A solution of 1 part of salicylic acid and 3 parts of sodium phosphate in 50 parts of water, promotes the healing of granulating surfaces.

CHONDODENDRON or CHONDRODENDRON?

BY DANIEL HANBURY.

In the *Pharmaceutical Journal* for Nov. 14, it is remarked that the authors of the *Pharmacographia* prefer to write *Chondodendron*, and not as the derivation of the word would seem to require, *Chondrodendron*. The proposal to insert an r in the second syllable emanated from Mr. Miers, who, in his *Monograph of the Menispermaceæ*, states that the word was originally mis-spelt through an error in the press.

As this name, which is that of the genus to which the Pareira Brava plant has been shown to belong, may come into more frequent use than hitherto, it is well that we should know what reasons may be urged in favour of each way of spelling.

The genus made its first appearance in the work of the Spanish botanists Ruiz and Pavon, entitled *Floræ Peruvianæ et Chilensis Prodromus, sive novorum generum plantarum Peruvianarum et Chilensium descriptiones et icones*, published at Madrid in 1794. Here we find it *Chondodendron*, with the derivation explained thus—"*a granorum copia quibus arboris truncus et rami obsiti sunt.*" This is in allusion to the Greek word χόνδρος, signifying *a corn, grain, or any small roundish mass;* and is appropriate to the plant by reason of the little black warty spots that cover the bark, chiefly of the younger wood.

From such an origin, coupled with δενδρον, *a tree*, the word *Chondrodendron* would naturally result: but for some reason,—as I believe, for the sake of euphony,—the authors of the genus chose to drop the first r, and to write *Chondodendron*. That this was by no typographical error is obvious. The word occurs again and again; and though there are enumerated several "*erratas de impresion*," *Chondodendron* is not among them. Four years after the *Prodromus*, the authors published their *Systema Vegetabilium Floræ Peruvianæ et Chilensis*, in which they still retained *Chondodendron*: in fact, the name has been almost universally accepted.

Thus De Candolle in his *Systema*, published in 1818, as well as in the first volume of his *Prodromus*, which appeared in 1824, wrote *Chondodendron*; and so the word is adopted by Pöppig and Endlicher*, Lindley in his *Vegetable Kingdom* (1853), Eichler in the *Floræ Brasiliensis* of Martius, Bentham and Hooker† (1862), and lastly by Baillon in his *Histoire des Plantes*‡ (1871).

With the sanction of such an overwhelming amount of authority, I am satisfied to accept the name without an attempt at improvement. It has served for eighty years in botanical literature, and may fairly claim admittance to that of pharmacy.

SULPHOCARBOLATES.

BY GEORGE BROWNEN, F.C.S.

The sulphocarbolates having come pretty extensively into use, a notice of one lately examined and found peculiarly impure may be of interest, and prevent these salts from falling into unmerited disrepute.

The specimen was labelled "sulphocarbolate of soda;" it had a disagreeable odour, and a pink colour.

It precipitated solutions of barium nitrate and chloride, and the precipitate from a hundred grains of the so-called "sulphocarbolate," after washing, etc., left an insoluble residue of barium sulphate, equivalent to 11·5 per cent. of crystallized sodium sulphate.

That carbolic acid (?) in a somewhat loose state of combination existed in this sample was proved by heating a strong solution of the salt and condensing the vapour in nitric acid; on diluting this acid, picric (carbazotic) acid was precipitated.

Other tarry compounds, fixed and volatile—probably of the phenyl or benzene series—formed the remainder of the impurities found in this sample.

It seems probable that this salt must have been made by a careless operator from the formula given in the *Pharmaceutical Journal* for Jan., 1869, p. 429; and a few remarks on that formula may not be amiss, especially as the process requires some skill or care to be successful. Acids of known strength should be used and heated to the proper temperature to ensure combination, avoiding on the other hand an excessive heat, which would decompose the acid into tarry matters and other compounds of the phenyl series. If the carbolic acid was pure and exactly sufficient to change the whole of the sulphuric acid used into sulphocarbolic acid, then any salt required might be prepared by neutralizing the acid with the special base.

If free sulphuric acid be found in the sulphocarbolic, it might be combined with an additional quantity of carbolic acid, or removed by the cautious addition of solution of barium hydrate as long as a precipitate of barium sulphate occurred—an excess of baryta should be avoided, as barium sulphocarbolate is soluble; this, however, would not matter much if an alkaline salt was required, for an alkaline carbonate would displace barium as the insoluble barium carbonate. Pure salts might also be obtained by decomposing barium or lead sulphocarbolates with sulphates, as noticed in previous journals.

Volatile, odorous, and tarry compounds should be avoided or removed, their therapeutic value being unknown, and their presence in a definite salt objectionable.

Sulphocarbolates (at least the sodium salt) are pretty stable compounds; I do not think they are liable to spontaneous decomposition.

I admit that this is an exceptional case, possibly publicity will prevent its recurrence.

ALKALOIDAL COMPOUNDS WITH IODINE.*

BY HARRY S. BAUER.

(*Concluded from p. 403.*)

Compounds of Morphia with Iodine.

Morphine Hydriodate.—$C_{17}H_{19}NO_3,HI + 3H_2O$.—Morphine dissolved in aqueous solution of hydriodic acid forms after some time a white silky crystalline salt, readily soluble in hot water, ether, and alcohol, and difficultly soluble in chloroform. Pelletier first described this salt, but the author is unable to confirm his statement that it is soluble in cold water. Winkler obtained it in four-sided prisms, by adding two parts of acetate of morphine to one part of iodide of potassium.

Morphine Sesqui-iodide.—$2\,C_{17}H_{19}NO_3, 3\,I$.—Upon rubbing together two parts of morphine with one part of iodine the mass is coloured red-brown, and upon being heated with alcohol is entirely dissolved. Upon dilution of the alcoholic solution reddish brown crystalline plates are deposited, which are soluble in alcohol, ether, and chloroform; in cold acids they are insoluble, but become soluble upon the application of heat.

Morphine Tetra-iodide.—$C_{17}H_{19}NO_3HI_4$.—When a morphine salt was added to a solution of iodine a kermes brown precipitate was immediately formed, which was separated by decantation and dissolved in alcohol. Upon dilution of the alcoholic solution a dendritic crystallization was deposited. Finer crystals were obtained by dissolving the precipitate in solution of iodide of potassium.

Morphine tetra-iodide is soluble in alcohol, chloroform, benzol, and solution of iodide of potassium; ether and carbon bisulphide dissolve traces. Nitric and hydrochloric acids dissolve it with a fine red colour.

An iodic salt of morphine cannot be prepared; for instance, if morphine be brought into contact with iodic acid, iodine is set free by the formation of morphine sesqui-iodide. The reducing action of salts of

* Abstract of a Paper in the *Archiv der Pharmacie*, for October.

morphine upon iodic acid is very characteristic. After dilution of a morphine salt to one part in 10,000, the iodine set free by the decomposition of iodic acid may be detected by means of chloroform and carbon bisulphide. According to Lefort, the reaction is rendered yet more delicate by the addition of ammonia. All the foregoing morphine iodides when dissolved in alcohol have a brown yellow colour, and are changed by hyposulphurous acid and hyposulphite of sodium.

Compounds of Veratrine with Iodine.

Veratrine Periodate.—This salt is formed upon bringing together alcoholic solution of veratrine and periodic acid as a pitchy mass, in which, under the microscope, crystals may be detected. The author reserves further particulars.

Veratrine Tri-iodide.—$C_{32}H_{54}N_2O_8, HI_3$.—If a veratrine salt be added to a solution of iodine a kermes brown precipitate is immediately produced, which is easily dissolved by the addition of alcohol. Evaporated at a gentle heat a red-brown amorphous mass is obtained, readily soluble in alcohol, chloroform, and ether; insoluble in water and cold and hot benzol. Only traces are soluble in carbon bisulphide. If, in the evaporation, a heat above 60° C. be used, a tarry mass is produced which cannot be evaporated to dryness.

The estimation of the iodine was made by precipitation with silver nitrate; this, however, gave too high a result, some iodate being mixed with the iodide of silver precipitate.

As this compound contained hydriodic acid besides two atoms of iodine, the author treated some by shaking it with metallic quicksilver. The result was a double salt in which only two atoms of quicksilver had been taken up. The compound might therefore, perhaps, possess the following constitution:—

$$C_{32}H_{54}N_2O_8, HI \begin{matrix} / \, I \\ \| \\ \backslash \, I \end{matrix}$$

Compound of Strychnine with Iodine.

Strychnine Tri-iodide.—$C_{21}H_{22}N_2O_2, HI_3$.—This iodide appears to have been previously obtained by Herapath, who prepared it by warming one part of strychnine, dissolved in one part of alcohol and three parts of water, together with a little tincture of iodine. Upon allowing the mixture to cool spontaneously, fine six-sided prisms were deposited. Herapath attributed to this compound the formula $C_{21}H_{22}N_2O_2, I_3$. The same compound has been described by Tilden, who gave it the correct formula, but calculated it from different results.

The author obtained this iodide in violet-coloured prisms, similar to those of permanganate of potassium, upon mixing together sulphate of strychnine and solution of iodine, dissolving in alcohol the precipitate produced, and evaporating. Its very remarkable optical properties were described by Herapath. For instance, a crystal placed under the micropolariscope so that the axis is vertical to the polarized ray appears to be almost white; but if placed so that the long axis is parallel to the polarized ray it appears nearly black.

Strychnine tri-iodide is readily soluble in alcohol, with difficulty in ether, water, chloroform, benzol, and carbon bisulphide. The alcoholic solution is very unstable, whilst the undissolved compound can withstand a temperature of 135° C. Sulphuric and nitric acids dissolve this iodide with a red coloration. Strong ammonia decomposes it in the cold, as also does nitrate of silver. Alcoholic solution of the strychnine tri-iodide heated with alcoholic solution of cyanide of potassium becomes coloured, but upon cooling does not deposit strychnine cyanide, as the author expected, but the unaltered potassium cyanide. The alcoholic solution of the tri-iodide mixed with an excess of alcoholic solution of iodine, and heated in a sealed tube by means of a water-bath, yielded a compound crystallizing in black prisms, which upon admitting air into the tube was decomposed into a tarry mass, containing much free iodine besides unaltered tri-iodide. (The residue probably of a higher iodized product?)

Compound of Brucine with Iodine.

Brucine Tri-iodide.—$C_{23}H_{26}N_2O_4, HI_3$.—This compound is obtained by precipitating a solution of sulphate of brucine with solution of iodine. The voluminous red brown precipitate is washed by decantation, and dissolved in a sufficient quantity of alcohol. After slowly cooling, the solution gives a crystallization of long, bronze-coloured needles.

Brucine tri-iodide is soluble in alcohol, chloroform, and benzol; insoluble in water, ether, and carbon bisulphide. It dissolves in dilute acids upon warming. After long contact with the acids the compound is decomposed, and iodine vapour is given off.

The behaviour of this compound with polarized light is very remarkable, being quite the reverse of that of the strychnine tri-iodide. Placed with its axis parallel to the polarized ray, the crystal appears to be of a clear yellow colour; placed vertically, it appears to be brown, with a bluish shade. Its behaviour in alcoholic solution is analogous to that of the strychnine tri-iodide.

*Compound of Coniine with Iodine.**

Hydriodated Coniine Tri-iodide.—$3(C_8H_{15}N) HI, I_3$.—Geiger has stated that when iodine is triturated with anhydrous coniine, at first a blood red, and afterwards an olive-green mass is formed, which is partially soluble in water. Blyth has said that alcoholic solution of iodine, mixed with alcoholic solution, gives a yellow turbidity, which quickly disappears, and that upon evaporating this solution *in vacuo*, there remains behind a brown mother liquor and crystals, which are readily soluble in water, alcohol, and ether. The author sought to obtain this substance in a crystalline form by adding coniine dissolved in alcohol drop by drop to an alcoholic solution of iodine, until the whole of the coniine was precipitated without any excess of iodine solution remaining. There resulted at first a turbidity, which quickly disappeared. The alcohol was therefore evaporated at a gentle heat, when there remained a pale yellow-coloured mass, smelling strongly of coniine, readily soluble in water, alcohol, ether, and chloroform; insoluble in cold and hot benzol; only yielding traces to carbon bisulphide. Dissolved in water and allowed to stand during a week over chloride of calcium, pale yellow perfectly formed octahedra were deposited, which smelt strongly of coniine. From solution in ether it crystallized in stellate groups.

After several unsatisfactory attempts at analysis the author obtained concordant results by adopting Carius's method of heating the alkaloidal compound

* Abstracted from the *Archiv der Pharmacie* for October p. 214.

in a closed tube with nitric acid and silver nitrate. Five experiments gave a mean of 57·370 per cent. of iodine, from which the formula $3(C_8H_{15}N),HI,I_3$, was calculated, which requires 57·466 per cent. of iodine. It was sufficiently evident that the compound contained hydriodic acid, for when it was shaken with metallic quicksilver, a double salt was formed, into which three atoms of mercury had been taken up.

The author's experiments were conducted in the laboratory of Dr. Wittstein, at Munich.

THE DIAGNOSIS OF BLOOD-STAINS.*

The *American Journal of the Medical Sciences* for July contains a paper, by Dr. Joseph G. Richardson of Pennsylvania, on the "Value of High Powers in the Diagnosis of Blood-Stains," as a sequel to a former paper on the same subject in that journal for July, 1869. He then stated that the residuum of a dried blood-clot left after the action of pure water, long mistaken by Virchow, Robin, and others, for pure fibrin, was composed chiefly of the cell-walls of the red blood corpuscles, and that, by proper management, these capsules of the red discs could be brought clearly enough into view, to enable him to measure them accurately, and so distinguish the dried blood of man from that of an ox, pig, or sheep, with a certainty disputed by previous observers. He regards this theory of the possession of a cell-wall, deduced chiefly from experiments upon the gigantic blood-discs of the Menobranchus, which are nine times as large as human ones, in which crystals of hæmato-crystallin were seen to crop out of a visible membranous capsule, as the foundation of his success in recognising and measuring blood-discs. The experiments of Owsjanniskow and Dr. Roberts, and the examination of blood-discs upon a dark ground, tend to confirm Dr. Richardson's views. The conclusions then published have not yet met with general acceptance; and a considerable part of the present paper is occupied with answers to theoretical objections. In the course of the argument, he aptly compares various sized blood-discs to shot of different sizes (numbers). It is to be remembered that, whilst the relative differences between corpuscles of human, ox, and sheep's blood remain the same, the absolute difference becomes more perceptible in proportion as the discs are magnified, so that when the former appear nine-eighths of an inch, and the latter five-eighths of an inch across, they can hardly be mistaken for one another.

Among one hundred freshly drawn red corpuscles, from five different persons (three white males, one white female, and one black female), the average of mean diameters was $\frac{1}{3378}$th of an inch. The measurement of twenty corpuscles from part of the first of these specimens, hastily dried in a thin film upon a slide, gave a maximum of $\frac{1}{2800}$, a minimum of $\frac{1}{3621}$, and a mean diameter of $\frac{1}{3182}$th of an inch. It can be shown that the smallest of human red discs, whether dried or fresh, are larger than the largest corpuscles of an ox, or, *à fortiori*, of a sheep. Professor Wormley brought Dr. Richardson a slide of human blood, upon which were seven corpuscles, designated by numbers on a drawing. Dr. Wormley's measurements gave an average of $\frac{1}{3236}$ of an inch; whilst Dr. Richardson's, with $\frac{1}{25}$ immersion-lens, gave an average of $\frac{1}{3266}$ of an inch; while some of the measurements (made independently) were identical. Virchow's objections he meets by stating that contraction in drying only increases the differences between the red discs of oxen, horses, pigs, sheep, deer, and goats, and those of man, since all the above are much smaller. But all theory is now practically set aside, inasmuch as Dr. Richardson has solved the question so far by experiment. Professor J. J. Reese and Dr. S. Weir Mitchell sent him three samples of blood, on paper, from ox, man, and sheep, simply numbered 1, 2, and 3, with no clue to their origin. No. 1 was treated as follows:—Some small particles were broken up into a fine dust with a sharp knife upon a glass slide, and treated with a solution of common salt, containing 0·75 per cent.; after covering with thin glass, this was then absorbed at one end by blotting paper, whilst fresh was added from the other end—thus washing away all colour. Then aniline was added, and in its turn washed away by salt. The specimens Nos. 2 and 3 were similarly treated, and all examined under $\frac{1}{25}$ immersion-lens, giving, with the A eye-piece, a power of 1250 diameters. Ten of the most perfect discs in each were examined, giving the following results. Dr. Richardson gives all the measurements in the original.

No. 1...	Minimum, $\frac{1}{3572}$;	Maximum, $\frac{1}{3125}$;	Mean, $\frac{1}{3407}$.
No. 2...	" $\frac{1}{4878}$;	" $\frac{1}{4444}$;	" $\frac{1}{4694}$.
No. 3...	" $\frac{1}{6666}$;	" $\frac{1}{5405}$;	" $\frac{1}{5828}$.

Now Gulliver's measurements are $\frac{1}{3200}$, $\frac{1}{4267}$, and $\frac{1}{5300}$ for human, ox, and sheep's blood respectively, and his own experiments had prepared him for slight contraction; he therefore decided that No. 1 was human; No. 2, ox's; No. 3, sheep's blood, which was so.

Three other specimens were treated with liquor iodinii compositus, with these results: No. 1, a mean of $\frac{1}{4662}$; No. 2, of $\frac{1}{5952}$; No. 3, of $\frac{1}{3430}$ for ten measurements. The conclusions were that No. 1 was ox's blood; No. 2, sheep's blood; No. 3, human blood, which again proved correct.

Dr. Richardson says that Robin's favourite solution of sulphate of soda is too prone to crystallize, and often contains large quantities of a peculiar fungus, the spores of which closely resemble human blood-discs. He thinks no fluid equal to the 0·75 per cent. solution of chloride of sodium. Fragments scraped from the edges or thinnest parts of the blood-stain are best, as freest from fibrin. A fragment from a blood-stain prepared in May, 1869, after five years, could still be distinguished from those of ox and sheep; and the mean of ten measurements gave $\frac{1}{3425}$ of an inch—the corresponding average five years ago being $\frac{1}{3474}$ of an inch.

He concludes, therefore, that the results of the above experiments prove, that since the red blood globules of the pig ($\frac{1}{4230}$), the ox ($\frac{1}{4267}$), the red deer ($\frac{1}{4324}$), the cat ($\frac{1}{4404}$), the horse ($\frac{1}{4600}$), the sheep, ($\frac{1}{5300}$), and the goat ($\frac{1}{6366}$) of an inch, are all so much smaller than even the ordinary minimum size of the human red disc, as measured by him, we are now able, by the aid of high powers of the microscope, under favourable circumstances, to positively distinguish stains produced by human blood from those caused by the blood of any of the animals just enumerated, and this even after the lapse of five years from the date of their primary production. This question is one eminently deserving the attention of English medical jurists and microscopic observers. It can be no longer possible to ignore these interesting researches of Dr. Richardson. We would, however, earnestly caution that no opinion should be given unless founded upon measurements of several blood-discs, and after much practice with the micrometer and the power employed.

* From the *British Medical Journal*, Nov. 28.

PREPARATION OF SULPHOVINIC ACID AND ITS SALTS.*

BY T. L. PHIPSON, PH.D.

The preparation of sulphovinic acid is by no means an easy operation, and, as certain compounds of this acid are now beginning to be used in medicine, perhaps the following observations may not be devoid of some practical interest.

When sulphuric acid and alcohol are mixed together without any special precautions, the temperature rises, and a certain quantity of sulphovinic acid is formed at once; but as in the formation of this acid a certain proportion of water is set free, and prevents the continuation of the reaction, it is never completed, even after the mix-

* From *The Chemical News*, vol. xxx., No. 781.

ture has been kept for some hours in a water-bath, and at a higher temperature decomposition at once ensues. It may, nevertheless, be quite possible to obtain a sulphovinic acid tolerably pure with alcohol and sulphuric acid alone (instead of the present tedious method based on the decomposition of the baryta salt), by keeping the mixture at 100° for two or three days and not acting upon too large a quantity. I intend to try this experiment shortly.

To obtain sulphovinate (ethyl-sulphate) of lime, it is best to mix equal volumes of concentrated sulphuric acid and alcohol; they may be mixed without any special precautions when small quantities only are used, and the uncovered vessel containing the mixture must be transferred to a water-bath and kept there eight or ten hours at least, during the whole of which time the temperature should be 100°, or nearly. The liquid will then have acquired a slight degree of fluorescence and a decided odour of ether (not an odour of sweet oil of wine), and should be only very slightly coloured. When cool, it is added, drop by drop, to about twenty times its volume of cold distilled water, carefully avoiding any rise of temperature, and keeping the liquid well stirred. This solution is saturated with pulverized chalk, added in small quantities at a time, until effervescence ceases. When a slight excess of chalk has been added, filter off the sulphate of lime, heat the filtrate in the water-bath with a little carbonate of lime for about half an hour, filter while warm, and evaporate at a heat not exceeding 100° till a permanent saline layer forms at the surface;* then place the capsule in a moderately dry place. In about twenty-four hours the crystals are formed; the mother-water will give another crop when allowed to evaporate over sulphuric acid or chloride of calcium. If the chalk contains iron or manganese, their sulphovinates remain in the mother-water, and are perfectly separated by pressing the crystals.

Sulphovinate of lime crystallizes rather slowly even in very concentrated solutions; it forms large, brilliant plates, something like chlorate of potash; its composition is represented by $C_4H_5O, SO_3 + CaOSO_3 + 2\,HO$; it is very soluble in water and in alcohol. The impure salt can easily be purified by re-crystallization from alcohol.

Sulphovinate of baryta has a similar composition and similar properties; it can be obtained in the same manner. When the crystals are pure, they form very large, brilliant plates, oblique rectangular prisms, modified in certain angles. Both this salt and the lime-salt often present a peculiar pearly aspect, which I do not observe on small pure crystals; these are perfectly transparent, and I believe this pearly aspect to be mainly owing to minute quantities of carbonate or sulphate dispersed through the larger crystals.

The sulphovinate of soda could be obtained pure from either of these salts without difficulty, but, for the preparation of the pharmaceutical product on a large scale, it is more economical to make it directly. I hope to refer again to this compound.

JAPANESE VEGETABLE WAX.†

The *Japan Mail* contains some further particulars respecting the preparation of the vegetable wax produced in Japan, and chiefly exported to England. This wax is obtained from the fruit, or, more correctly, berry, of the wax tree. The tree, which is by no means unlike the juniper tree, flourishes more especially in the southern provinces of the empire. The fruit, which usually ripens about the month of October, is gathered when ready, and cleansed from its loose, outer husk, a process which is accomplished in large wooden vessels, with wooden malls, similar to those in use for cleaning rice. The residue product, available for the manufacture of wax, is a bean-shaped kernel of the size of a lentil, possessing an unusual degree of hardness, of a dark yellow wax colour, and offering a saponaceous exterior to the touch. The kernel is subsequently exposed in a sufficient degree to a steaming process, which deprives it of its extreme hardness, and allows of its oily properties being more easily extracted in the pressing stage. In this process the oil is received into small earthen vessels, in which it subsequently hardens to a bluish-green mass, in the shape which it is commonly met with in home consumption.

Wax so produced is impure, and is only suitable for certain descriptions of candles and for wax-thread manufacture for home use. In order to render it merchantable for the exporter, the following refining process is resorted to:—The wax is boiled with a lye until it is brought to a perfectly fluid state, and is then drawn off into a reservoir filled with clear water, the pure wax, which floats upon the surface, being removed. The mass is then exposed to the sun's rays for a period of fifteen or sixteen days, during fine weather, for the purpose of bleaching it, at the expiration of which time the wax presents a dirty white crumbling appearance and a strong tallowy smell. The boiling and bleaching are repeated with the view of rendering the refining process still more complete, the only difference being that, instead of lye, pure water alone is employed in boiling it. The product is a clear white powder, which, in place of its former crumbling appearance, has assumed an almost crystalline formation. The last stage of preparation for export consists in rendering the powder a compact mass, which is effected by melting it over a fire with a little water (in order to avoid burning), and running it off into flat vessels. The product thus obtained, and known to commerce as vegetable wax, differs exceedingly little from white beeswax, with which it possesses the properties of colour, brittleness, and similarity in its fan-shaped fracture in common. The only characteristic difference may be said to be in the odour, the beeswax giving off a refreshing aromatic scent in burning, while the tallowy smell of the Japanese wax is far from being agreeable. Vegetable wax is chiefly used in England in the manufacture of wax candles.

THE HYPOPHOSPHITES.*

BY CHARLES G. POLK, M.D.

The hypophosphites, introduced to the medical profession by Dr. Churchill on the erroneous theory that they supply phosphorus to the system, and thereby restore the normal amount of that element which he considered to be deficient in phthisis, and from which deficiency he supposed the tubercule was caused, have outlived the excitement attendant on novelty, and have attained an official position in our pharmacopœia. Without being a panacea for phthisis, hypophosphorous acid and its salts have proven to be valuable companions for cod-liver oil in this and other wasting diseases. Further research has demonstrated that hypophosphorous acid exists in the brain and nerve structure in combination with glycerin and fat, and that it is a deficiency of this, and not uncombined phosphorus, which lies at the foundation of this frequent and fatal malady. Churchill erred in the selection of neutral salts instead of free acid. Therapeutically, nitrate of potassium is not the same as nitric acid; neither is muriate of ammonium muriatic acid. The alkali salts are not always indicated, and if continued through the protracted treatment required in chronic diseases they impair the *crasis* of the blood, and do a detriment uncompensated for by any good which can accrue from their use. With the free acid, and with its combinations with iron and manganese, these objections do not obtain. Time and again I have tested them with marked advantage, and have learned to regard them second only to cod-liver oil in staying the development and progress of tuberculosis. As is well known,

* During this evaporation, a slight, but distinct, odour of butyric acid is perceptible.

† From the *Journal of the Society of Arts.*

* From the *Tennessee Pharmacal Gazette,* for November.

there are two syrups—the ferric syrup and the ferrous syrup. The former is obtained by decomposing sodic or calcium hypophosphite with ferric tersulphate. The following is a formula I formerly followed for a physician who used the syrup of the ferric hypophosphite considerably :—

℞. Sodic Hypophosphite	256 grs.
Sol. Ferric Tersulph.	q. s.
Acid. Hypophosph. Sol.*	1 oz.
Syrup q.s. ad	12 oz.

Decompose the sodic hypophosphite with sufficient of the iron solution, wash the ferric hypophosphite, dissolve it in the acid, and add the syrup.

The ferrous hypophosphite, owing to its extreme solubility, requires a different mode of manipulation. It has been proposed to form it by decomposing ferrous sulphate with sodic hypophosphite. By making highly concentrated solutions of the ferrous and sodic salts the greater part of the ferrous hypophosphite will be precipitated, and can then be dissolved in syrup acidulated with hypophosphorous acid, so that each drachm will represent about five grains of the ferrous salt. The proportions for forming ferrous hypophosphite thus are five parts of iron to eight of sodium. I do not deem it the most economical or the most satisfactory process. I have found the following to give a valuable syrup, although the process does not come under the laws of double decomposition :—

℞. Ferrous Sulphate.	15 drs.
Potassic Hypophosphite	1 oz.
Hypophosphorous Acid.	14 oz.
Sugar	14 oz.
Water, sufficient.	

Dissolve the iron in five ounces of boiling water, and the potassic hypophosphite in ten ounces of boiling water, mix the solutions ; let it stand in a closely-covered vessel two hours, filter on the sugar, and add the hypophosphorous acid solution. No doubt there exists some sulphuric acid and sulphate of iron, and also some hypophosphite of potassium ; nevertheless, therapeutically, I have found it a fine combination, and the most economical of any I have tried. The following is my choice for making syrup ferrous hypophosphite :—

℞. Fresh Ferrous Oxide	q. s.
Hypophosphorous Acid	5 oz.
Sugar	8 oz.

Saturate three ounces of the acid with the ferrous oxide, add the remainder of the acid and the sugar, and dissolve without heat. Each drachm will contain about six grains of ferrous hypophosphite almost entirely free from any impurities. This is the formula I give the preference. I am indebted to my friend Mr. Creuse, of New York, for it.

Another formula I have used for a dozen years is to decompose ferrous sulphate with calcium hypophosphite, pour off the supunatant solution from the sulphate of calcium, evaporate with gentle heat, filter on sugar, add hypophosphorous acid, and dissolve. I am confident, however, that I have derived better results from manganese than from iron, and from both than from either alone. The satisfactory formula for a combination for these agents is yet a desideratum. I use the following :—

℞. Ferrous Oxide	256 gr.
Manganese Hypophosphite . . .	256 gr.
Hyphosphorous Acid	10 oz.
Sugar	10 oz.

Dissolve the iron and manganese in the acid, add the sugar, and dissolve. To this I add hypophosphite of ammonium, when disease does not contra-indicate, in the proportion of three grains to each drachm. It preserves the syrup, and also enhances, in a very positive manner, its therapeutical properties. If it be desirable, one grain of quinia and one-fortieth of a grain of strychnia may be given with each dose. Thus administered, I have found it, in conjunction with cod-liver oil, to arrest the progress of phthisis in a decidedly positive degree. I can recall many cases in which the cure seems permanent. In the wasting diseases of children in which there seems to be a deficiency of lime in the system, with general impairment of the nutritive functions, the following combination has done very well in my hands :—

℞. Calcii Hypophosph. recent. . . .	256 gr.
Manganesii Hypophosph. recent, .	64 gr.
Acidi Hypophosph. Sol.	2 dr.
Syrupi q.s. ad.	16 oz.
M.	

Teaspoonful thrice a day to a child of two or three years of age. I usually combine this with an aromatic elixir of calisaya, which makes it agreeably tasted and therapeutically more efficient.

* The strength of this solution is not indicated in the original, but we presume it is to be understood that only sufficient is to be used to dissolve the respective precipitates of hypophosphites.

PHARMACY ACT, 1868.

RECTIFICATION OF THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS.

We are requested by the Registrar to publish the following List of persons whose names will be erased from the Register unless they communicate with him on or before 30th December next.

*Those marked * are Pharmaceutical Chemists.*

Adcock, William	49, Vauxhall Road, Birmingham.
Adey, Edward Linnell.	5, Oak Villas, Park Road, Hornsey, N.
Alcock, Alfred.	290, Shales Moor, Yorks.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 28, 1874.

THE COUNCIL OF THE PHARMACEUTICAL SOCIETY AND THE IRISH PHARMACY BILL.

MISCONCEPTIONS are shadowy creations that are frequently evoked with a facility in inverse proportion to the difficulty experienced in allaying them. In fact, were it possible to apply the doctrine of abiogenesis to abstractions, misconceptions would certainly supply forcible illustrations of its truth. One good illustration might be found in the subject-matter of two letters from Professor TICHBORNE, which are printed at pp. 399 and 439.

The first of these letters, although commencing with a profession of admiration for the dissertations of Messrs. GILES and PROCTOR, so evidently disclosed a *raison d'être* in an opportunity for breaking a spear with the Council of the Pharmaceutical Society of Great Britain, on behalf of an indefinite number of sufferers from its action in respect to the Irish Pharmacy Bill, that we ventured to append an opinion that the writer was labouring under some misconception. In his second letter, Professor TICHBORNE, appreciating at least our intention, says that he is "pleased to be disimbued of that impression," which he had shared with others, and then proceeds to make an assertion which is a reiteration in a specific form of a grievance which could only have been inferred from his former general statement. He states that "the Select Committee appointed to investigate the "Irish pharmacy question was informed that the Phar- "maceutical Society would give no assistance to an "educational movement in Ireland, although it would "be urgently required."

So far, this definite statement is a step in advance, since it can be brought to the test of facts. The question need no longer remain an affair of impression, or memory, or misconception on either side, because the official "minutes of evidence taken before the Select Committee" are published, and may be purchased for a few pence. In our opinion, arrived at after hearing that evidence and reading it in its printed form, no information was given before the Committee which could be so construed as to identify it with Professor TICHBORNE's statement. Possibly the impression was produced by trusting too much to oral reports as to the nature of the evidence; but if there be any more tangible ground for it in the printed report, Professor TICHBORNE will confer a favour by pointing it out.

Indeed, the attitude—or absence of attitude—hitherto taken by the executive of the Pharmaceutical Society in respect to the Irish pharmacy question has been inconsistent with the charge of antagonism to pharmaceutical education in Ireland. At the time of the passing of the Pharmacy Act, 1868, its extension to Ireland was abandoned on the ground that there were difficulties which could be better dealt with in a separate Bill. Such a Bill the Attorney-General promised to introduce if in office the following year; but, that condition failing, the legislation did not take place. Amply occupied by the increased labours thrown upon it by the passing of the Pharmacy Act for Great Britain, there was nothing to induce, or even excuse, the Council in taking the initiative in seeking legislation for Irish pharmacy. It was known that the Apothecaries' Hall of Ireland had prepared a draft Bill; it was known also that several interviews—sometimes amicable and sometimes the reverse—had taken place between the authorities of the Hall and the Chemist and Druggists' Society of Ireland. But no official communication was made to the British Council, and it seemed possible that the interviewing might serve for a perpetual illustration of the old adage, "Amantium iræ amoris integratio est," when, without any notification of its intention, the King and Queen's College of Physicians introduced its Bill to extend the provisions of Pharmacy Act, 1868, to Ireland.

So little was this step expected that there was no time to consult the whole Council. A Committee hastily summoned to consider an application to give evidence before the Select Committee decided upon telegraphing immediately to Mr. MACKAY, asking him to attend as a representative from Scotland, and Mr. SANDFORD gave evidence as a former President of the Pharmaceutical Society. Of course so informal a deputation was incompetent to advocate or oppose any course in the name of the Society, and consequently it did not do so. All that was done was to describe the nature of the operations of the parent Society and the North British Branch, and to express an opinion that what the Society had done in Scotland—neither more nor less—it would be willing to do in Ireland. We fail to see that in this there was anything antagonistic to pharmaceutical education in Ireland.

But a later sentence in the second letter, which alludes rather censoriously to the relation of the Society to its School of Pharmacy, allows of the inference that perhaps the culpability of the Council, in Professor TICHBORNE's eyes, lies not so much in having done any positive wrong as in not doing what might have been hoped for. If the absence of an offer to provide a School of Pharmacy for Ireland, where Professors paid by the British Society should impart, upon terms more or less remunerative, the education afterwards to be tested by a Board of

Examiners appointed by the same Society, be construed as antagonistic to pharmaceutical education, then we think it probable that the Society will remain antagonistic.

Without depreciating the value of pharmaceutical education in the least degree, we would remark that throughout the discussion of this question there has been a curious affectation by our Irish brethren of superiority in educational requirements and business advantages. It has been assumed that directly upon the passing of such a Bill as that brought forward last session, there would be an exodus from Great Britain of chemists and druggists, of all degrees of efficiency, eager to clutch the pharmaceutical prizes dropping from the hands of the Irish apothecaries. The nature of these prizes may be gathered from the words of Dr. LEET, who gave evidence on behalf of the Apothecaries' Hall, with which institution Professor TICHBORNE is also honourably connected. He says:—

(Q. 118.)—"The object which we have in view is, to supply a want which is felt in certain districts in Ireland, which are not the best fields for practice and making money. A man who occupied the position of pharmaceutical chemist in those remote districts would have a struggle for existence, and must resort to every kind of trade for a subsistence."

Again:—

(Q. 48.)—"If they could exist in those places you would find apothecaries, but the eagle will not be where there are no carcases."

And yet the same gentleman, describing the Apothecaries' Hall Bill, had said (Q. 8), "We say Pharmaceutical Chemists, because a mere Chemist and Druggist would not meet our purpose, as proposed by that Bill." Ordinary mortals would perhaps have been content with the "mere chemist and druggist," and have had some chance of the attainment of their objects.

In referring to this subject in these columns, our wish is to assist in dispersing the unfounded impressions respecting any sinister aims of the Pharmaceutical Society against Irish pharmacy, which appear to have gained currency. Although we do not speak authoritatively, we believe that if the Irish pharmacists desire to stand alone British pharmacists will be well content; but if, on the other hand, they wish to secure the co-operation of the Pharmaceutical Society of Great Britain in promoting pharmaceutical education—not in educating pharmacists—in Ireland, that Society would be ready to co-operate on the same terms as obtain in England and Scotland. If this result, however, is ever to be accomplished, it is necessary that some almost childish misconceptions and apprehensions should be abandoned. To show that we do not speak without cause, we quote a passage from the evidence of Sir Dominic Corrigan, which is only typical of much more that he said:—

(Q. 598.)—"Then with regard to the Pharmaceutical Society of England, do you suppose that there would be a arge increase of funds to the British Pharmaceutical Society, if the society formed in Ireland were united with it?—(A.) Of course they would take every penny from us, and give us nothing in return. I think the case is quite clear."

(Q. 599.)—"And that is one of your objections to the union, is it not?—(A.) That is a very serious objection."

Considering that the only legitimate source of revenue would be the fees for examinations, which are not sufficient in this country to defray the expenses attending them, and that any deficiency would have to be made up from the voluntary annual subscriptions of the Members and Associates of the whole Society, the amount that would be brought over to England yearly, even if "every penny" were brought, is a problem worthy of the acute intellect of Sir DOMINIC to elucidate.

RECTIFICATION OF THE REGISTER.

THIS week our pages contain a List of about three hundred persons whose names will be erased from the Registers of Pharmaceutical Chemists and Chemists and Druggists unless they communicate with the Registrar before the 31st December next. Only two years have elapsed since a similar list was published, and it is difficult to believe that nearly so many unreported deaths of registered persons have occurred during that time. On the former occasion more than 25 per cent. of the persons so advertised afterwards communicated with the Registrar, and probably at least as large a proportion of those on the present list will do the same before the close of the year. Such a result can only arise from gross neglect and carelessness on the part of the only persons beneficially concerned. If it be remembered that at least two registered letters have been sent to everyone on this list, and returned through the Dead Letter Office, it will be acknowledged that the Pharmaceutical Society has a right to complain that so much trouble and expense should be thrown upon it, because so many persons are too neglectful or lazy to keep corrected the entries on the Register which are the sole evidence of their right to carry on their calling.

In default of the persons most interested in doing so, it would much assist the Registrar in keeping the Register correct, if upon any necessary corrections becoming known to our readers they would kindly communicate them to him. And on the present occasion it will not be out of place to ask that they would look through the published list and forward any information they may possess respecting the defaulters to the Registrar, 17, Bloomsbury Square, London.

MEAT PRESERVATION.

THE interesting discovery by Professor KOLBE of a method of preparing salicylic acid at a comparatively low cost, which is described on p. 421, promises to have a much wider interest than economy in producing a compound at present not very extensively used. For the discovery seems to have been consequent upon the result of numerous experiments which revealed that salicylic acid possesses valuable antiseptic and preservative properties. The importance this fact may assume in respect to the supply of food, may be inferred from the following statements. Professor KOLBE has found that fresh meat rubbed with salicylic acid may be exposed to the air for a week without spoiling. A large quantity of beef and mutton, prepared with salicylic acid, was packed closely together in a cask, and at the end of a month was then examined as to its usefulness in the kitchen and as to flavour. The greater part of the acid was removed by washing, after which the not unpleasant, weak, sweetish taste of the remainder could only be detected with difficulty. This favourable result suggested to Professsor KOLBE that by this means meat might be imported cheaply, yet in good condition and well-flavoured, from South America, where the excess supply is at present partially utilized in the preparation of extract of meat. Of course, if this be found practicable, other sources will be available, and this application of salicylic acid may have a great future before it.

THE VAMPIRE versus THE PHŒNIX.

Two or three years since the reading of a paper on the nutritive properties of blood, before the French Academy of Sciences, by M. BOUSSINGAULT, was followed by an epidemic of blood-drinking in Paris, where patients of both sexes and all ranks and ages were said to have flocked to the slaughter-houses to drink the still smoking blood of slaughtered oxen. According to the *Philadelphia Record*, the taste has now migrated across the Atlantic. Inquiry at the slaughter-houses has revealed the fact that there are in the city of New York nearly two hundred persons who are in the habit of drinking, as food and medicine, blood warm from the oxen. Sheep's blood, it appears, is not in favour; but it is said that if the patient's eyes be closed the blood of beeves, warm from the neck, has the same taste as milk warm from the cow, and is far more efficacious for weak lungs than cod-liver oil. Should fresh bullocks' blood ever be added to the widening list of articles that the chemist and druggist, as purveyor to the members of the healing art, has to keep for sale, the gilded phœnix which still decorates many a shop front might well give place to the vampire, should an authentic model be forthcoming.

ACCLIMATIZATION OF IPECACUANHA IN INDIA.

IN the last report of Dr. KING, the Superintendent of the Calcutta Botanic Gardens, he states that the propagation of the ipecacuanha plant by root and leaf cuttings has been so successful that there is at present a stock of 63,000 living plants; whereas four years since there were at the Cinchona Gardens but twelve cuttings, of which seven were afterwards accidentally destroyed.

THE MIDDLESEX CORONER.

THE effort put forth by the medical profession to secure the return of a medical gentleman to the Middlesex coronership, vacated by the death of Dr. LANKESTER, whose predecessor was the late Mr. WAKLEY, has been completely successful. The election took place on the 19th inst., when 1164 votes out of 1972 were recorded for Dr. HARDWICKE.

ANALYSTS' CERTIFICATES.

THE *Medical Press and Circular* has long suspected the existence of a roguish dodge of sending a specially excellent sample of an article to an analyst, and then using his certificate to cover the sale of an enormous quantity of a product entirely different and vastly inferior in quality. Referring to the recent use of a certificate of tea given by Dr. SAUNDERS, and we suppose with a full knowledge of the facts of the case, it stigmatizes the conduct of the brokers in terms which we, not possessing such information, cannot venture to reproduce here.

SOCIETY OF PUBLIC ANALYSTS.

A GENERAL Meeting of this Society will be held at the Cannon Street Hotel, on Tuesday, December 1st, at four o'clock p.m., to receive a report from the Committee appointed at the meeting held on August 7th; to appoint scrutineers to examine voting papers for Officers and Council; to consider and decide upon the constitution and rules of the Society; to consider the Definition of Adulteration submitted by the Committee; and to deliberate upon the steps which it is desirable to take to further the Amendment and Consolidation of the Adulteration Acts.

THE SCHEELE MEMORIAL.

WE are requested to say that the Subscription List for the SCHEELE Memorial Fund, which is now lying at 17, Bloomsbury Square, will be finally closed on the 15th December. We take the opportunity of announcing the following subscriptions that have been received up to the present time:—

	£	s.	d.		£	s.	d.
Bell, J. and Co.	1	1	0	Schweitzer, J.	1	1	0
Bradley, J.	1	1	0	Southall, W.	1	1	0
Hills, T. H.	1	1	0	Williams, John	1	1	0
Morson, T.	1	1	0				

THE NEXT EVENING MEETING.

AN Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, December 2nd, when a paper on an Additional Method of Testing Glycerine, by Professor GODEFFROY, of Vienna, and one on the Preservative Action of Chloroform upon Vegetable Infusions, by Mr. J. B. BARNES, will be read. The Chair will be taken at half-past Eight precisely.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The second monthly meeting of the above Society during the present session was held, under the presidency of Mr. G. F. Schacht, at the Bristol Institute, on Tuesday, November 17. The subject of the evening was the following lecture on—

Chinese Therapeutics.

BY DR. F. PORTER SMITH.

It is impossible to contemplate an isolated race of some 400 millions of human beings without a thought of the *immense* quantity of physic such a mass of *civilized* fellow-creatures as our Chinese brothers and sisters must be daily consuming! The drug bills of such a people must represent an enormous sum of money, all of which they have the satisfaction of spending amongst themselves. For the Chinese are a patriotic physic-taking people, spending large sums for particular remedies, and for what we should call patent medicines. The yellow bills of quack-doctors take up more than half of the room of the hoardings of Chinese towns and cities. Filial piety, the great civilizing morality of Chinese society, finds no more fit or frequent exercise of its principle of devotion to the parent than in the purchase of some "restoring pill," or cordial, for the revival of the strength of some longevous individual of a Chinese household, with its harmonious members of at least three generations. Large sums are often spent in the treatment, by a secret and costly remedy, of some young concubine, pregnant in the old age of her master, whose wives have failed to present him with anything better than wenches, all duly consigned to a watery grave, save perhaps two, kept sometimes for a worse fate. But these remedies are eclectic, as our American friends would call them, or homegrown. Visions of these large Chinese populations taking large quantities of sugar-coated pills, seidlitz powders, and tinctures are all to be demolished, for the Chinese make the only drug which they import in any quantity into an article of daily use, or rather abuse. I allude to opium, largely imported into China from British India. This drug is now being produced in China and Tartary in much larger quantities, and much better quality, than formerly. So great are the barriers of dialect and distance in the huge Babel-land of Cathay, that the medicinal products of some far-off province of the Chinese polyarchy have all the novelty of a foreign drug to the people of another province. The study of "Chinese Therapeutics" must therefore be one of *curious*, rather than *commercial*, interest to us all, this evening, in our brief survey of the subject in hand.

The alternations of great heat and intense cold of the climate of China, the very irregular cultivation and occupation of the vast territory of 5,300,000 square miles, and the exigencies of continually recurring flood, drought, famine, epidemics, and rebellion, or external war, combine to produce a fearful amount of disease amongst the population, and, notably, disease of external parts, such as the skin, eye, etc. This latter circumstance has given great prominence, as we shall presently see, to all topical remedies. Still, that fondness for the use of strong external applications in almost all cases of sickness, which is characteristic of all Oriental people, is in part due to a wholesome dread of attacking the internal parts of the body, of which they have very scanty and incorrect information. Dispensaries, asylums, and lazarettos have existed, for many hundred years, in China, as the pure result of heathen sympathy with suffering humanity, apart from the higher motives of Christian feeling. This admission is important, and made after very careful investigation. It is not a *claim* made by the Chinese, but a *fact* established by their municipal records. Taxes and voluntary contributions are made for the support of free dispensaries, etc., in every large city, and many of the native druggists, to their credit be it spoken, give medicines gratis to the poor. It is not one of the least important of the indirect effects of Protestant medical missions in China that they have stimulated the exertions, and multiplication, of these local native charities in some of the large cities of the land.

Whilst there is much that is crude, disgusting, and senseless in some of the methods and means of Chinese doctors, it is important that we should avoid all libellous caricatures of the subject. The early Jesuit missionaries, to whose self-denying labours the Chinese owe so much, and to whom we are so largely indebted for our early knowledge of Chinese literature, were not always *sufficiently* careful in their translations of native works on medicine, etc. The missionary Hervieu made a mistake of some hundreds of years in the date of an old work on the pulse, and actually took the trouble to translate, by mistake of course, a *spurious* edition of a well-known classical treatise on this (to the Chinese physician) important subject. He thus contributed to place the doctrine of the Chinese faculty on this subject in a much less favourable light, and, worst of all, the translated account has been greedily copied by all subsequent European writers. Similarly in the translation of works on "Chinese Therapeutics," which have a voluminous literature of more than twenty centuries, the queerest names and things have been given by European critics. To give an instance of this fun-making tendency of translators, there is a well in the Yang-Kuh district of Shantung province, whose waters, like those of Barèges, in France, would appear to contain a sort of mucilaginous principle. These waters are directed to be evaporated, and the extract resulting to be strengthened by the addition of the glue made from the skin of any one of several animals, amongst which the ass is certainly, but not prominently, mentioned. Straightway, seizing the most ridiculous part of the subject, the European translator stamps this article of the Chinese materia medica with the nickname of "*Asses-Glue!*" The dried lining membranes of the stomach of the fowl (domestic) has been long used by Chinese doctors in the treatment of disorders of the stomach, bowels, etc. What have we here but an anticipation of the modern use of pepsine in the very disorders mentioned in native works? In the Pharmacopœia of the Royal College of Physicians of London, for 1721, we have this very same substance, officinalized under the name of "Pelliculæ stomachi gallíæ interiores," almost a literal translation of the term used for it in the Chinese Pharmacopœia. It was ejected from the London Pharmacopœia in 1746. It was the last remnant of a whole host of cheap and nasty remedies, such as the coagulum taken from the stomach of the leveret, or the lamb, "stercus bovinum, humanum, pavonis," etc., etc., which distinguished or disgraced the pharmacopœias of Europe, in the 17th and 18th centuries, but which still remain in the unreformed *Pun-tsau-Kaung-muh* of the Chinese prescriber. This last-mentioned and interesting work of 1597 is usually published in some thirty-eight or more volumes, and has three volumes of plates, etc. It represented and embraced the observations of about eight hundred authors, and the writings embodied in some thirty-nine previous publications. This work, of some forty years of literary and experimental labour, was a "Synopsis of Ancient Herbals," a name which is justified by the fact that 1096 out of 1892, the whole number of officinal genera of drugs, are referred to the vegetable kingdom, which grows with such imperial magnificence in China. There are 11,896 formulæ given throughout the work, which has been reprinted in the form of at least four principal editions, but without any additions, or excisions. Chinese medical writers and practitioners have always gone on the assumption that *every* natural and artificial substance in existence is possessed of medicinal and curative, or antidotal, properties. Their pharmacopœia, the *Pun-tsau*, is therefore their most complete work on natural history. This comprehensive belief has led them into the successful, though completely empirical employment of many crude substances, which constitute useful and shrewd anticipations of particular isolated drugs or active principles which we seem to have long waited for, until we could obtain them in more individualized and perfect form or condition. Their use of animal "materia medica" is very considerable. Many parts of the human body even are reputed to be endowed with special medical properties. In fact, at least some thirty-nine different parts, or secretions of the human body are mentioned in the *Pun-tsau* as medicinal in their effects. This accounts for instances of apparent cannibalism after Chinese executions. Soldiers often seize the liver, gall-bladder, or heart of an executed man, and cook them as means of adding to their pluck or courage, which they curiously locate in the biliary secretion. The bodies of animals remarkable for their strength are thus eaten. The skin of the elephant is thus used as a plaster. By the way, they believe our india-rubber of commerce to be elephant-skin, and call it often by the same name. The horn of the rhinoceros is made into a drinking-cup, and water or wine allowed to remain in the cup, to confer supposed tonic properties upon it. The bones of fossil animals (often extinct) confounded with the assumed remains of their stock heraldic emblem, the dragon, and also fossil ivory, are officinal. The testes of some animals, dressed up as if in imitation of castor-pods, are eaten to provoke virility, the great ambition of every Chinaman. In fact, "Kirby's pills" of phosphorus would be a "real blessing" to Chinese would-be-fathers, and a great source of profit to any enterprising exporter of drugs to the "Flowery Land." Cantharides are given in hydrophobia.

It must not be supposed from their fondness for vegetable materia medica that the Chinese faculty do not employ mineral medicines. Sal ammoniac, urea, orpiment, realgar, white arsenic, calomel, corrosive sublimate, æthiops mineral, alum, and copperas, are all used as drugs, but the wholesome clauses of the excellent Tartar Code of laws in force in China have checked many daring dabblers in such useful drugs. Sulphur, realgar, and some other substances are made into cups, and wine or water placed in them to acquire alterative, anti-periodic and antidotal properties. Poisoning is commendably rare in China, but suicide by means of watery extract of opium is very frequent in some parts of the country, as the mode of most "happy despatch," as the Japanese would call it. This extract of opium, though carefully prepared, is not so narcotic in its effects as might be expected, for a considerable quantity of refuse, ash, etc., from opium pipes is added to the mass, to render it more bulky and combustible. Would-be importers of Chinese "prepared opium" into England should be cautious in their selection of samples, even when prepared, as has been the case at the treaty-port of Amoy, under foreign supervision.

Every part of a plant, shrub, or tree has distinct properties assigned to it in Chinese Therapeutics. The properties of the stem, or ascending axis of a plant, are assumed to be antagonistic to those of the root, or descending axis, as a rule. The root of a plant, upon which they set greatest store, may thus be used as an antidote for the effects of the leaves of the same medicinal plant. The pollen of many plants is officinal, and sundry empyreumatic preparations of vegetable substances are largely enumerated in the *Pun-ts'au*. The particular properties of medicinal substances are described in such choice, archaic, or idiomatic terms as can only be translated by the free use of such words as alexipharmic, pectoral, lenitive, carminative, alterative, etc., which have long been, or ought to be, discarded from our pharmacologies. Dr. Paris would have delighted in a Chinese prescription, with its eight or ten different ingredients, answering as many distinct indications. Adjuvants, correctives, corroborants, distributives, etc., are employed under cover of the most elaborate and irresistible justifications. Vehicles, menstrua, and syrups are always directed in special formulæ; those of the Rhamnus or Zizyphus genera being in great favour. Decoctions are the favourite form of Chinese prescribers, the dose being large, hot, and final. For upon the exhibition of a single draught of a carefully, solemnly contrived and concocted formula do the Chinese doctor and druggist stake their credit. The collection of drugs sufficient for the momentous experiment is packed up in a sort of pyramidal or triangular parcel, with the finer doses all separately packed and tied at the top, and the grosser, meaner constituents at the base. The whole pile, tied in position by coarse string or straw, without outside wrapper, hanging and swinging by the finger of the purchaser, looks much more like a lot of purchases from the grocer or oilman than from the druggist. It is an important part of the proceeding that the dregs of the draught should be thrown deliberately into the middle of the street, the patient being supposed to part with the disease at almost the same time. Thus the Chinaman literally throws his physic to the dogs, so common in Chinese streets; but he does it more sensibly—after having exhausted its properties. The usual directions to the compounder (whose shop always wears a festal garb, and is bright with beaded oil lamps), or to the patient, are on this wise:—The medicines to be slowly boiled in a clean vessel, without a cover, and with as little disturbance in the way of stirring, or suddenly lifting from the fire, as possible. The principal compound decoction containing the substances directed against the main symptoms of the disease is called the *Ta-t'ang*, or "grand ptisan." The menstrua, or disguises, are called the "minor draught." A second boiling of the drugs is often carried out when the drugs are costly.

Placebos, diet-drinks, simples, and domestic remedies are much employed, and have special names. In fact, the Chinese are great nominalists rather than realists. There could not possibly exist in Chinese medical works such things as the "os innominatum," or the "arteria innominata." Attached to the Chinese prescription for the better class of patients is the "pulse-table," which explains the nature, seat, cause, treatment, and prognosis of the disease.

Very much importance is attached by both doctors, druggists, and patients to the grave question of diet during the administration of medicines. Very rigid and minute instructions are given in reply to the invariable question of the patient to the doctor, "What do you forbid?" as to "what to eat, to drink, and what to avoid." The universal practice is to avoid the five alliaceous condiments in daily use amongst the Chinese—namely, garlic, onion, etc.; game of certain kinds, such as the wild goose, the flesh of the carp, and of the blenny, the flesh of the dog, the plowing ox, and of the domestic cock. Some of these restrictions are suggested by the general adherence of the Chinese people to the Buddhistic faith, which preaches against the destruction of animal life. This same creed enforces the use of vegetable oils and fats, in place of those of animal origin, in pharmaceutical processes, in the arts, and in household cookery. Surgical patients with tumours are specially forbidden to eat the flesh of the cock bird. Although many of their prohibitions are absurd, yet some of their hygienic and dietetic directions show a degree of appreciation of the importance of these auxiliary measures.

Certain drugs, such as arsenic in its various forms, calomel, opium, nux vomica, and native cantharides, are not allowed to be sold by druggists in the ordinary way. Securers are required to put in their appearance for the sale of arsenic. Nux vomica beans are only to be sold for killing dogs, those pests of Chinese streets and villages (of which they are the scavengers, in part), and opium is not allowed to be sold (as a drug by druggists) or prescribed. In fact, this last drug has no place in legitimate medicine. It is scarcely correct to say that the cultivation of the poppy has been forbidden by statute. When some immaculate public censor has memorialized the throne, a virtuous proclamation has appeared against it. The Tartar Code provides that one month's wearing of the cangue or square wooden collar, and banishment for life, to serve in the frontier army, shall be the punishment for those who traffic in opium, and that their abettors shall receive one hundred blows, and banishment from their native country for three years. Those who by opening illicit opium-saloons shall seduce the sons, or relatives, of decent families shall have sentence of death by strangulation recorded against them. It is unnecessary to say that these laws are not carried out at present. To keep an opium-shop it is only necessary to fee the constable, and stick a square of used filtering-paper, showing the black patch of the dregs of the watery solution of opium-extract, against the half-closed shutters, and the whole thing is safe and sure. A regular duty is assessed upon the foreign (East Indian) opium, and the native drug is fast replacing the former. Chinese home-produced opium is well worth the attention of the English drug buyer, as the drug is carefully prepared, seldom adulterated, and is very efficacious in medical practice. The seller and buyer of arsenical and other metallic poisons, contrary to the statute, are punished with the bamboo, and exiled for a time, even if the poison has missed its mark. If the drug should prove fatal, both parties have sentence of death recorded against them, which is commuted to imprisonment during the imperial pleasure. The procuring of abortion by means of the mylabris and the blistering cicada, in common use as epispastics, in China, is frequent, and is punishable by exile to a distant province. The twenty-fifth volume of the code, under the head of capital offences, requires sentence of death to be recorded against any practitioner of medicine who abuses his professional opportunities to destroy his patient. This and the question of malpraxis is determined by reference to medical assessors, and is punished, in its minor degrees, by prohibition from future practice. Instances of malicious actions-at-law against medical practitioners who have incurred the displeasure of litigious patients, or have ventured upon some unsuccessful innovation on the ordinary rules of practice, are not unfrequent.

The Chinese have for ages been conversant with some part of the processes of the fluid circulations of the human body. From their minute description of certain physical, as well as sympathetic communications between the various organs, and between the trunk and the extremities, it is evident that they must have practised some sort of coarse dissection at some early period. Their defective drawing is quite sufficient to explain the rudeness and incorrectness of their curious anatomical plates. It is moreover to be remembered that in their *earlier* history the Chinese offered human, as well as animal, sacrifices, so that their opportunities for observation of the general structure of the human body have been undoubted. Their later Buddhistic prejudices have prevented such desirable researches. Their physiology and pathology is physico-vital, and they have borrowed from both solidists and humouralists. Whilst their therapeutical practice is to be described in general as allopathic, it is impossible to describe their theories of the action and applications of medicines without a brief reference to their principles of philosophy or cosmogony. From a monad, or ovum mundi, there is produced, by a primary segmentation, a male or seminal principle, and a female or germinal principle. The *yang*, or male element, is nearly synonymous with light, heat, phlogiston, motion, action, contraction, positive electricity, clearness, dryness, and tonicity, and is peripheral. The other dual element, the *ying*, or female influence, is passive, inert, turbid, sombre, relaxed, moist, cold, antiphlogistic, negative, and interstitial. The *ying* has capacity, but the *yang* is characterized by exertion. The *ying* is not superior to the *yang*, though commonly enumerated first, as rest usually precedes motion. The *ying* is visceral, lunar, and telluric, tends downward and centrically, and resides more particularly in the heart, lungs, liver, spleen, and the kidneys. The *yang* is solar, external, determines upwards, is specially located in the small and large intestines, the stomach, the gall-bladder, the testes, and the urinary organs. It is pathologically identical with external flushes, inflammatory excitement, sanguineous exudation, and peripheral excretion. The *ying* includes the condition of passive congestion, like that of the stagnant focus of an inflamed part, and commonly ultimates in secretion and flux.

Altogether this doctrine runs somewhat parallel with the common theory of typical inflammation. It has served, in Chinese medicine, much the same purpose as the neater, more matter-of-fact, stock doctrine of vascular action, and its consequences, of European pathology, namely, to connect together the few genuine *facts* actually observed.

The blood, as a whole organ, and its secretions, are spoken of in Chinese medical language as the *ch'ing*, and belong, for the most part, to the *ying*, which resembles the *anima*, or vegetative life of the body. When Chinese doctors describe a tonic medicine, they speak of it as restoring or repairing the material and the dynamical elements, the *ying* and the *yang*, in their proper sufficiency and proportion.

Medicines are originally divided into those which develope the *ying*, and those which develope the *yang*. The nature of the individual drug is also distinguished from its notable, or extrinsic, properties, and referred to the *yang*, as the latter is to the *ying*. A disease which is characterized by ascendancy of the *yang* is treated by a medicine which calls forth the *ying*, and *vice versâ*.

As these principles are too recondite for ordinary minds, Chinese medical authors usually speak of the *ying* as cold, and of the *yang* as heat. A cold medicine is given in a hot disease, which is something like our talk about using refrigerant medicines in febrile diseases. Hot medicines are said by some luminous authorities to be given in combination with cold remedies, as auxiliaries, to modify the morbid chill, which may have been the antecedent cause of the heat. All diseases characterized by weakness and chronic flux, and especially of the kidneys and testes, which they call by the same generic name (distinguishing them only as *outside* and *inside*) are spoken of as *ying*. Stimulant, tonic, astringent, alterative, derivative, diaphoretic, rubefacient, and counter-irritant medicines are *yang*, and would be given in diseases attended with debility, remora, and passive flux. Emetics, purgatives, antiphlogistics, and resolvents are included under the *ying*.

Another relation is sought to be established betwen medicinal agents and diseases through the five (Chinese) elements, metal, wood, water, fire, and earth. No such element as air is ever reckoned amongst these five factors of all things. There is a primordial essence, or subtle basis of all created things, sometimes called in Chinese a breath; but Duhalde and his copyists must have been thinking of the four elements of Western philosophy when they replaced wood by air. The viscera of the human body are connected with these elements. *kin*, or metal, rules the lungs; *muh*, or wood, the liver; *shwui*, or water, the kidney; *ho*, or fire, is related to the heart; and *tou*, or earth, to the stomach. Certain rules, as to the supposed mutual generation or mutual opposition of these five elements, are the guides of the prescriber in the choice of his remedies.

Much importance is attached by Chinese writers and practitioners to the influences of the seasons. The element of wood is said to prevail in spring, and as this is connected with the liver, such is the result of this conjunction that hepatic and splenic diseases are most frequent in the spring quarter of the year. Fire is associated with summer, justly enough in a warm climate, and with the south, and cardiac affections are said to predominate then. This is a fact; cases of sudden syncope and death, with no head-symptoms, are common in the midst of Chinese thoroughfares, crowded, and covered in as they are with large mat-frames, stretched across from the houses on one side to those on the other. These communications between the houses render a fire in summer, in a large Chinese city, a fearfully and widely destructive thing. Autumn is related to metal, and, therefore, its associated viscus, the lung, is said to be injuriously stimulated. As metal opposes wood, liver diseases are somewhat frequent at this period, as the liver is said to be depressed. In winter, when water is in the ascendant, the kidney is thought to be excited to morbid action. The element earth has four periods of morbific influence, namely, in the third, sixth, ninth, and twelfth months. At such periods, the stomach and the spleen, which is also related to earth, are unusually liable to disease. Much of this is all stuff and nonsense. There is, however, a clue to be made out, by means of which some practical rules, of great utilily to foreigners resident in China, might be deduced f:om the actual *facts* observed by a few reliable native authors. So much attention has been given to this subject of seasonal influences, that a separate class of practitioners confine themselves more or less to this speciality, and have a distinct name. Astrology and alchemy have both had an evident influence upon Chinese medicine.

Traces of the existence of a sort of homœopathy are found in the common phrases "with a poison to attack a poison,"—"to combat hot diseases by heat."

Setting aside all other considerations, it is a stubborn fact that the Chinese doctors are able to render a considerable amount of prompt relief to their patients, and that without such a slavish attention to the mere treatment of prominent symptoms as might be expected. The statements of educated Europeans, who have submitted themselves, at first from necessity, and subsequently from choice, to native doctors, in China, sufficiently attest the truth of this assertion, made after a good deal of previous scepticism felt upon the point.

Contrary to what might have been expected in so exclusive a country as China, some of the plants in common use as drugs, or articles of diet, are not indigenous to the country. The grape-vine, the cotton-plant, and the tobacco-plant are all admitted to be of foreign origin. There is a division of fruit-bearing trees in the *Pun-tsau*, devoted to foreign additions to the full catalogue of excellent native fruits. Persia, India, and Arabia are often referred to as the sources of valuable drugs and perfumes, and there is a remarkable frankness (for the Chinese) exhibited in acknowledging obligations of this kind.

The carefully prepared catalogues of the tribute sent by the states and sovereigns tributary to the Chinese emperor, give us examples of many new things introduced successfully into China in this way. It was a prescribed and regulated privilege of the servants of the retinue of these ambassadors, or tribute-bearers, as the Chinese term them, that they should be allowed to sell certain quantities of articles admired on previous occasions by would-be possessors of such rarities.

All presents by European Governments were interpreted by the Imperial Government as similar tribute. Holland, Russia, England, and the United States, like the Sultan of Sulu, in Borneo, are all enumerated amongst the tribute-sending countries, and strict ceremonies are solemnly set forth, in the court regulations, for the observances of "Her Majesty's Servants," assumed to be sent to do this suit and service before the Lord of the World.

Chinese doctors have long used arsenic in ague, mercury in syphilis, borax for whitemouth, iron as a tonic, corrosive sublimate as an escharotic, indigo in epilepsy, tar in skin diseases, and zinc as an astringent.

The pharmaceutical operations are performed by Chinese druggists with great care, but their drugs are often carelessly secured, conveyed, and preserved. Many substances, such as aconite and digitalis, are treated in such a way as most surely to deprive them of all useful properties. Thus aconite root, extensively used in China, so that a distinct set of dealers buy and sell it alone, is often treated, before drying it, with a week's soaking in vinegar! Distillation was learnt by them from the Arabians. Wooden mortars are largely used for pulverizing, and the powder is sifted over and over again, to produce an impalpable powder. Levigation and elutriation are frequently made use of, and most excellent samples of drugs are to be met with in the market, prepared in this way. Large quantities of cosmetic powders are consumed in China. The white face-powder, scented with musk, and containing a small quantity of the celebrated Borneo, or Baros, camphor, is a very agreeable application to the skin in cases of eczema, slight burns, or sun-scalding. Root-fibres and stems are set in a press, and planed off into fine sections for purposes of decoction and infusion.

Every drug-shop has its altar to the god or king of medicine. A foreign beer-tumbler filled with oil, and burning day and night, by means of a floating wick, before a gilt image of the god, is the newest thing in this way. The Chinese medical profession rejoices in a god of surgery, and there are at least ten canonized doctors in the Chinese calendar of saints and heroes. Charms, amulets, incantations, brass images, mirrors, and many other subsidiary means are used by the Tanist quack-priests, or Zadkiels, of China, to cure formidable or special complaints. The small-pox is deified and propitiated, which is at least more sensible than neglecting vaccination and all other known means of averting this plague of mankind. Scarifying, cupping, both bloody and dry, bleeding, artificial production of subcutaneous ecchymosis, ginger blisters, the moxa, the lamp cautery, copper discs heated in boiling water, drainage issues, and many other means or appliances, are or have been used in China for ages. Rude trusses are sold, and used in hernia, often confounded with hydrocele and some other diseases of the scrotum. In fact, pretty much the same mistakes are made in China as in Europe.

Hydropathy is strongly recommended in early medical works. The common and effectual use of very hot water as a drink in colds, fevers, etc., is instructive to us Europeans. They produce sweating, vomiting, expectoration, diuresis, and almost every usual effect of the most powerful medicines by means of this simple agent—water, *plus* heat. Doctors who prescribe for their patients at a distance, after examination of their urine, are met with in China. Worm doctors are numerous, for in the fruits of the quis-qualis, and other native drugs, the Chinese faculty possess several excellent vermicides. Chorea doctors are a separate class of specialists.

There is such a jealous separation of the province of the physician from that of the druggist, in China, and such a strict etiquette, by which collusion is endeavoured to be prevented on their part, to the detriment of their mutual client, the patient, that the pecuniary interests of the physician are said to be often seriously interfered with. Should the patient be rich, there is room for both. The doctors themselves are divided into "ordinary practitioners," and "celebrated doctors," as before the law. They style themselves as "literary," "self-taught," and the "hereditary doctors." These last are a very numerous and much trusted class of practitioners, as they are the secret holders of the traditions and recipes of their perhaps long line of related practitioners. As to departments of practice there are the "outside" (surgical), "inside" (medical), "ophthalmic," and "veterinary" doctors. The last are a very ancient craft, and have a literature of their own. Midwifery is not recognized as a distinct or legitimate branch of the faculty. A set of old dames, called "birth-hasteners," carry on this business. Distinct names are sometimes given to several minor specialities, such as small-pox doctors, children's doctors, &c. Travelling quack doctors have a distinctive name. There are medical officers of some sort attached to the staff of general officers, but there are no regimental appointments. There is a medical mandarin of the lowest rank, connected with each prefecture, and another of low grade, appointed to the district. These two officials are medical tutors, who are supposed to teach the graduates of the colleges connected with the prefectures and the districts, and to act as medical attendants upon the inmates of the jails.

The fee of the Chinese doctor is an honorarium, and delicately termed "thanks." Money for the three sedan-chair bearers, according to the distance which the beautifully japanned, brass-bound, blue-curtained chair has been carried rapidly over, is regularly given, and "refreshers" are given in severe cases requiring frequent visits. Doctors are not allowed to tout in any way for practice, or, as the phrase goes, "physicians must not go about knocking at folks' doors!" Some doctors are what are called "contract doctors," or engage to cure for a certain sum, or series of sums, to be paid at successive stages of the cure. Presents are given to the doctors, the articles given being covered, or rather garnished, with red paper, and carried openly and ostentatiously (as is always the case in China) through the streets, attended by a rabble of hired servants, dressed up in semi-military livery. It is an understood thing that either the half of the things sent are returned next day, or the retainers are handsomely rewarded. The gods or goddesses are not forgotten, and models of the parts affected, candles, incense, etc., are sent to the temples. The gods and doctors are both highly lauded in pithy sentences, engraved with gilt letters on gaudy tablets, which are hung up before or within the temple, or the doctor's house. The fame of a practitioner is to be measured by the number of those tablets at his residence, on which he is compared to the medical deities or heroes. The tendency of all communications in China is to hyperbole, compliment, and profuse idiomatic metaphor.

All prescriptions are required to be written plainly, in the vernacular language, for the Chinese have never made any excursions into foreign languages, only to return for their best nomenclature, to their own vulgar tongue.

Many amusing stories are told of the shrewd dealings of the Chinese people with their doctors, such as the statement that the Chinese emperor only pays his doctor when he is well; or the curious averment that the Chinese paterfamilias is "put to bed" at the same time as his parturient "better-half," and treated with the same diet and doctoring as she is. These stories are not true, for the "heathen Chinee" is not a bit more odd than many other fish in the great sea of humanity, of which he only occupies a great gulf. So, having caught some few facts out of this fishery, we once more come back to our own shores, a little entertained, and, perhaps, relatively enlightened by our short voyage in the direction of a very Old World, into which our thoughts have this evening been briefly projected.

LIVERPOOL CHEMISTS' ASSOCIATION.

The third general meeting was held at the Royal Institution, on Thursday, the 19th inst. Mr. A. H. Mason, F.C.S., President, in the chair.

Mr. Hugh Jones Hughes was elected a member of the Association. Donation of the *Pharmaceutical Journal* was acknowledged. The President announced that arrangements had been made for holding the chemistry class, which would commence on the following Thursday, at 9 a.m.

On this evening miscellaneous communications were dispensed with, to give more time for the lecture.

The lecturer, Mr. Louis Siebold, of Owens' College, Manchester, was introduced by the President as a man whose labours in scientific pharmacy had led to his appointment as professor in one of the first scientific colleges in the world, and also as editor of the 'Year Book of Pharmacy.'

The Lecturer commenced by saying that within the last twenty-five years the science of chemistry had been almost revolutionized. The volumetric relations of the constituent gases in hydrochloric acid, water, and ammonia were commented on, and the law illustrated that when whole volumes of the constituent gases were employed, the resulting compound, in a state of vapour, never occupied less than two volumes. The relations by weight in definite and multiple proportions led to an account of the atomic theory, the subject of the lecture. The Lecturer concluded by pointing out the results that have followed the adoption of modern views of molecular composition, in the artificial production of alizarine, coumarine, and other organic bodies, not by accidental discovery, but by scientific reasoning leading direct to the manufacture of the substance.

The lecture, which was listened to with the utmost attention by a large audience, partly composed of ladies, was illustrated by experiments and excellent diagrams.

After some remarks by the President, Mr. M. Murphy, F.C.S., proposed a vote of thanks to the Lecturer. He spoke highly of the clear and simple manner in which a difficult subject had been treated. He, however, dissented from some views which had been expressed, especially as to the identity of the force which held together the atoms in molecules of the elements, and that which united the atoms in chemical compounds. He thought that it was not certain that the increase of bulk in a gas on heating was entirely due to greater distance between the molecules, but that it might be partly due to expansion of the molecule itself. Mr. E. Davies seconded the motion, which was carried by acclamation.

Mr. Siebold replied briefly to the remarks which had been made, and thanked the meeting for the attention with which it had listened to him.

BRIGHTON ASSOCIATION OF PHARMACY.

On Friday last the inaugural supper of the current session took place at the Old Ship Hotel, at which many of the leading chemists in the town were present.

The chair was occupied by the President of the Association, W. D. Savage, Esq., J.P., and the vice-chair by Mr. G. J. Haddock. After supper the health of Her Majesty the Queen and the rest of the Royal Family was proposed by the Chairman, and received with the customary demonstration of loyalty. The Vice-Chairman then proposed "the Brighton Association of Pharmacy," coupled with the health of the President, Mr. Savage. Mr. Savage, in responding, spoke of the many advantages derived from associations of the kind, and although regretting that the Brighton Association was not in such a flourishing condition as those of many other large towns, he hoped that this year renewed efforts would be made on the part of the members, and that they would come forward with papers for the evening meetings which would result in their being better attended than they had been during the past year.

The Vice-Chairman next proposed "the Pharmaceutical Society of Great Britain," and coupled with it the health of the President, Mr. Thomas Hyde Hills. He said, representing as they did that evening the chemists and druggists of the large and important town of Brighton, he felt sure that the toast he had proposed to them would be well received. In speaking of Mr. Hills, he said no one had done more for the cause of pharmaceutical education in this country, and standing as he (Mr. Hills) did at the head of a firm which had been, so to speak, the birthplace of pharmacy, he felt sure, in calling upon them to drink this toast, they would do so with all the respect and honour due to him.

The toast was drunk with great enthusiasm.

Mr. Savage, in rising to acknowledge the toast on behalf of the Pharmaceutical Society, spoke of the unbounded liberality of Mr. Hills in the cause of pharmacy, and he said whenever there was a benevolent object in view, Mr. Hills was always ready with his purse to contribute towards it, and that through an acquaintanceship of many years he had always found Mr. Hills, as a personal friend, worthy of the greatest regard, and that when Mr. Hills retired from the Presidency of the Pharmaceutical Society they would find great difficulty in getting any one who could fill the chair more worthily or ably than he had done.

The other toasts were, the past and present Secretaries, the Treasurer, Mr. Cornish (with musical honours), and the assistants of Brighton, responded to by Mr. Cassie.

A few songs and a recitation served to enliven the evening, and after singing the National Anthem the proceedings terminated.

Proceedings of Scientific Societies.

BERLIN APOTHECARIES' ASSOCIATION.

At a meeting of the above Society, on Tuesday, November 3, a communication was read from Mr. Heubach in reference to Professor Kolbe's experiments with salicylic acid as an antiseptic, in which he entirely confirms the professor's statement as to the antiseptic action of salicylic acid upon saccharine substances and food material.

Mr. Kobligk called attention to the inspection of pharmacies, complaining on the one hand of the great necessity for a skilled and independent judgment on the part of the inspectors, instead of a clinging to the letter of often defective laws and ordinances, and, on the other, of the great carelessness of pharmacists in the purchase and testing of their goods; he considered that inspections at defined and known times were ineffective.

Mr. Kobligk also exhibited some specimens of resina scammoniæ, which had been prepared by him according to the directions in the Pharmacopœia Germanica. The yield was about 7 per cent. He further described the following methods of testing as worthy of notice:—

Estimation of Quinine in Cinchona Bark (Perrot).—The powdered bark is repeatedly exhausted with alcohol and an alkaline solution of sodium silicate, the evaporated filtrate treated with ether, the residue from the ethereal solution treated with sulphuric acid, and the resulting sulphate of quinine weighed.

Tests for Free Mineral Acids (Mohr).—(*a*) Pure acetate of iron so much diluted with water that several drops of potassium sulphocyanide solution cause no colouration, with the faintest trace of free acid, gives the well-known red colour. (*b*) A dilute solution of acetate of iron treated with a solution of iodide of potassium and starch acquires a blue colour in the presence of the slightest trace of free acid.

Method of Filtering Liquids containing Sulphur (Hager).—Some drops of carbon bisulphide are added to the turbid liquid, and after a good shaking the mixture is poured upon a moistened filter. The sulphur remains behind dissolved in the carbon bisulphide.

Test for Veratria (Weppen).—The smallest quantity of veratria mixed with powdered sugar gives, upon the addition of sulphuric acid, a splendid colour reaction passing from green into blue.

Herr Augustin then read the following communications:—

Oil of Wintergreen.—The interesting discovery of Kolbe, of a method of preparing salicylic acid from phenol and carbonic acid, also suggests the preparation of an artificial oil of wintergreen, that oil consisting principally of methyl salicylate. The oil obtained by distillation from *Gaultheria procumbens*, an ericaceous plant growing in the Alleghany Mountains in North America, contains also a hydrocarbon, named gaultherylon, $C_{10}H_{16}$. The principal ingredient of the oil of wintergreen, however, is the ether which on account of its agreeable smell is much employed in perfumery. The natural oil prepared from *Gaultheria procumbens*, and the two oil prepared from the Javan plants, *G. leucocarpa* and *G. punctata*, as suggested by De Vrij (*Pharm. Journ.* (3), vol. ii., p. 503), cost at present in commerce 18 to 20 thalers per kilo. The author thinks, therefore, that early communications respecting the composition of the methyl salicylate may be expected.

The next communication referred to the preparation of carbolic acid from oil of *Andromeda Leschenaultii*, by Mr. Broughton, as described in this journal (vol. ii., p. 281).

Citric Acid.—The Jahresbericht of Drs. Wiggers and A. Husemann contains a communication upon *Vaccinium Vitis-idæi*, from which it appears that the organic acids in the berries have been carefully studied by Graeger. He has found them to contain $1\frac{1}{4}$ to $1\frac{1}{2}$ per cent. of citric acid, and $\frac{1}{4}$ to $\frac{1}{3}$ per cent. of malic acid; and he believes that when the plant is plentiful the fruit might be used profitably in the preparation citric acid, and the more so because vinegar or alcohol can be obtained as a bye-product. The quantity of citric acid is dependent upon the ripeness of the fruit before gathering, the citric acid being more abundant in proportion to the ripeness of the berries but the malic acid is not altogether wanting in those that are perfectly ripe. Experiments have shown that by using sodium bicarbonate about half the quantity of acids could be removed and the sugar economized, it being possible to add to each pound of berries five to six grams of sodium bicarbonate without injuring either the colour or flavour of the fruit. The speaker stated that he had this year made some experiments upon the subject, and that he would revert to it at a future sitting of the Society.

CHEMICAL SOCIETY.

Thursday, Nov. 19, 1874; Professor Odling, F.R.S., etc., president, in the chair. After the usual business of the Society, Dr. C. R. A. Wright read a paper on the "Action of Organic Acids and their Anhydrides on the Natural Alkaloids, Part II," by himself and Mr. Beckett, being a continuation of that which he brought before the Society at the last meeting. Professor W. Ker Clifford then made a communication on "General Equations of Chemical Reactions," proving mathematically from the kinetic theory of gases, the generally adopted method for expressing chemical reactions. An interesting discussion ensued, after which the following papers were read:—"On Propionic Coumarin and some of its Derivatives," by W. H. Perkin, F.R.S.; "On the Composition of Autunite," by Professor A. H. Church; and "The Action of Bromine on Protocatechuic Acid, Gallic Acid, and Tannin," by J. Stenhouse, F.R.S. The meeting was finally adjourned until Thursday, December 5th, when papers on the "Formulæ of the Alums," by Mr. S. Lupton, and the "Colour of Cupric Chloride," by Mr. W. N. Hartley, will be read.

Parliamentary and Law Proceedings.

Sale of Fraudulent Musk.

This is a case of some interest to pharmacists; it was tried at the Court of Exchequer of Pleas, at Westminster, before Sir Fitzroy Kelly and jury.

Mr. H. A. Jeune, plaintiff, who is a broker in the City of London, sought to recover from Mr. A. Monjoseph, defendant, who is a drug merchant in the same city, the price of a caddy of musk weighing $19\frac{1}{2}$ oz., and valued at £32 13s.

The evidence went to show that, in the latter part of July last, plaintiff offered defendant a caddy of *fine Tonquin musk*; the latter did not at once purchase, but offered it to Messrs. Hallawell and Symes, export druggists of Liverpool, who replied that they could do with it if of fine quality; the defendant wrote plaintiff to this effect, and with his permission sent the caddy to his customers on approval, with a request that the pods should not be cut open or disfigured unless they were purchasers.

Dr. Symes made an examination of the pods, pricking with a needle in the usual way, and looking for stitches; they had, as a whole, the appearance of being genuine, and it was ultimately decided to purchase, accepting them, according to declaration, as fine Tonquin musk. About 10 or 11 days after, the pods were all cut open, and of the $19\frac{1}{2}$ oz. only $6\frac{1}{2}$ oz. were found to be musk, the remainder being earthy matter, etc. The pods of musk were then wrapped in tinfoil, and with the fraudulent ones were replaced in the caddy, and returned to defendant, who in turn offered them back to plaintiff, but he refused to take them, and brought this action to recover amount of invoice. On his behalf it was argued that it was the custom in the musk market to examine by pricking only, and not by cutting, and that the purchaser always took upon himself the responsibility of the contents, it being understood that musk was largely adulterated; and, further, he did not admit that the musk was offered back to him.

For the defence it was argued that whatever might be the custom in the market it did not rule in a sale by private treaty, where the article was specified and declared to be something which it afterwards proved not to be; fine musk had been purchased, but had not been supplied; it was not a question of quality, but of the actual nature of the article itself. The offer to return the whole, and retain and pay for the 6½ oz. musk, was proved, and the defendant stated that, although he had considerable experience in musk, he had failed to detect any appearances which would lead him to suppose these were fraudulent, until after they were cut open. Dr. Symes, in his evidence, said that he looked for stitches, but so ingeniously were they sewn that he failed to detect such till after cutting them open; he also identified the pods as those returned by his firm from Liverpool.

The Judge, in summing up, said that in all probability the fraud had been committed in China, and that both plaintiff and defendant were equally innocent of it, and it would be for the jury to say which of them was to suffer the loss. The evidence had narrowed itself into two points, and from these they should arrive at their decision. There was such a thing as buying an article from appearance without any declaration being made as to its nature; in that case as soon as the seller had handed over the article his part of the contract was complete. The plaintiff had, however, admitted having offered the contents of this caddy as fine Tonquin musk, and in so doing had contracted to supply the article named. The second point was one on which the law was very exact, viz., if the purchaser of an article keeps it for an undue length of time before he notifies to the seller that the article is not what it was declared to be at the time of purchase, then the responsibility rests with the purchaser, and he has no power to recover for any loss he may sustain. It was for the jury to decide whether in this case the article had been specified to be what it turned out not to be, and whether an undue time elapsed before this was notified and offered back to the seller.

The jury almost immediately returned a verdict for the defendant.

Alleged Attempt to Poison by Corrosive Sublimate.

On Monday, at the Worship Street Police Court, William Cherry was charged with attempting to murder his wife by poison. The wife, who refused to attend until she was summoned, deposed that on the 11th inst., on leaving home to go to her work, she took with her, as was her usual custom, some sugar in a paper, to use with coffee at the workshop. Having put some into her coffee, she noticed the coffee had a bitter coppery taste, and she threw away the first cupful and poured out another; for this she used some of the same sugar, and she noticed it had the same taste. She afterwards became ill, and went to St. Bartholomew's Hospital, where she was treated, and got well. The coppery taste remained during three days. Other workpeople who drank the same coffee were not affected. The remainder of the sugar taken to the workshop by the wife was examined by Dr. Pavy, who certified that it contained corrosive sublimate. Some evidence was given with the object of showing the source from which the prisoner might have obtained the poison, and the prisoner was remanded.

Suicide by Prussic Acid.

An inquest was held on Monday, at Brighton, upon the body of a gentleman named O'Brien, aged 22, who committed suicide by taking prussic acid. It appeared that the deceased had invested his money in English mines, and proceeded to Africa, where he failed in his profession, and on returning to England learned that his investment was also a failure. The jury returned a verdict of "Temporary insanity."—*Echo.*

Review.

The Chemical History of a Candle. A Course of Lectures delivered before a Juvenile Audience at the Royal Institution. By Michael Faraday, D.C.L., F.R.S. Edited by William Crookes, F.C.S. London, Chatto and Windus.

This volume, which professes to be the chemical history of a candle, has in reality a very much wider scope than such a name might be supposed to indicate, for it not only contains a description of the nature and properties of the elements concerned in the combustion of a candle as well as of the products of its burning, but supplies also brief accounts of some of the physical forces by whose agency the operation is carried on, and draws an instructive comparison between the phenomena of combustion as ordinarily seen in carbon compounds and the respiratory function in animals.

The lecturer introduces his subject by giving an outline of the *modus operandi* in the production of some of the principal kinds of candles; tallow, paraffin, and wax candles receiving a due share of attention. The account given of the manufacture of the latter, though quite intelligible to any one conversant with the process, will, we are afraid, not be perfectly understood by children reading it for the first time. A woodcut, for the purpose of illustrating what Faraday's model did on the occasion of the lecture, would have rendered this much more complete.

A brief reference to the more ornamental kinds of candles follows, in which allusion is made to some prominent disadvantages connected with them; then the lecturer passes on to notice the cup formed immediately below the flame, and the nice adjustment of forces necessary for its production and preservation.

Attention having been directed to these points, the question, "But how does the flame get hold of the fuel" is made the text of an exceedingly intelligible dissertation upon capillary attraction in general; this is succeeded by an experiment illustrative of the vaporous condition of the fuel when burnt, and some remarks upon the form of the flame, and the influences determining this form.

Thus far the first lecture.

We must content ourselves with merely giving a *résumé* of the plan pursued in working the subject out in the succeeding lectures.

After showing that air is necessary to the combustion of a candle, and describing the cause of its luminosity, the lecturer enters upon the largest division of his subject, in which he speaks of the products of combustion. Some of the heads, around which are clustered interesting facts and beautiful experimental illustrations, are:—Water: its properties in the solid, liquid, and gaseous states; its decomposition. Hydrogen: its properties; product of its combustion; the decomposition of water by the voltaic current, and its recomposition from the resulting gases. Oxygen: the combustion of various elements in it; tests for free oxygen in the air. Nitrogen: its importance as a diluent in the atmosphere; weights of gases and method of ascertaining them; practical evidence of the atmospheric pressure. Carbonic acid gas: its properties; its occurrence in the breath; its use in the economy of nature; the analogy of combustion and respiration. Carbon: its presence demonstrated in sugar, carbonic acid gas, etc.

These, and many other matters relevant to the subject, are treated in a manner which cannot fail to interest and instruct any children into whose hands the book may be placed.

A striking feature of Faraday's mode of imparting knowledge is seen in this volume—we allude to the beautiful manner in which, instead of presenting isolated facts to his hearers, the lecturer seeks rather to supply the necessary data for their inference, and thus to lead his audience to those just conclusions which he afterwards verifies by experiment.

In one or two cases an editor's foot-note would have been of advantage, in showing that some of the statements, apparently absolute, are in reality relative only. Thus, the clashing that occurs between the statements—first (p. 154), that oxygen is insoluble in water, and then p. 185), that fishes "respire by the oxygen, which is dissolved from the air by the water," would have been prevented by the former being a statement of the comparative solubility of oxygen, hydrogen, and carbonic acid gas in water.

After the course of lectures we have been considering, comes a lecture upon Platinum, which is a very concise and practical account of its extraction, both by the wet process and that devised and employed so successfully by Deville.

Notes and Queries.

HYPODERMIC ADMINISTRATION OF MEDICINES.—Dr. Ernest Sansom states (*Med. Times and Gazette*, Oct. 31) that he has overcome some of the difficulties attending the use of solutions for hypodermic injection, by using gelatine discs containing definite quantities of the alkaloid or other active principle. When a solution is required for use one of the discs is dissolved in two or three drops of water placed in a teaspoon, and warmed over a spirit lamp or candle. Solution takes place in a few seconds, and the fluid is at once taken up into the syringe and injected.

NEW ANTISEPTIC DRESSING.—At a recent meeting of the Medico-Chirurgical Society of Edinburgh, Professor Lister described a new antiseptic dressing which he had used successfully in a case of rodent ulcer where the ordinary antiseptic dressing of gauze impregnated with carbolic acid, with a protective layer of oiled silk, would have been unsuitable. It consisted of an ointment composed as follows:—

Boracic Acid, in fine powder	1 part.
White wax	1 "
Paraffin	2 parts.
Almond-oil	2 "

The ingredients, after being mixed by melting the wax and paraffin, are stirred in a warm mortar till the mass thickens, and then set aside to cool, after which the firm substance is reduced in a cold mortar, in successive portions, to an uniform soft ointment. This is spread thin on fine rag, and when the almond-oil leaves it, as it soon does through capillary attraction of the porous external dressings, a smooth firm layer remains, consisting of blended wax and paraffin, together with the boracic acid, which comes off from the skin without leaving any greasy substance adhering, and does not at all confine the discharge, which, while freely shed, is perpetually supplied with a sufficient quantity of the boracic acid to ensure absence of putrefaction, while not preventing cicatrization. The *London Medical Record*, commenting on the above, says:—"A still better application for cases of this kind is an ointment composed like that above described, except that instead of one part of boracic acid, it contains half the quantity of salicylic acid, the antiseptic virtues of which have been quite recently discovered by Professor Kolbe, of Leipzig, who has also found out a method of manufacturing it cheaply. Salicylic acid, while possessing very remarkable antiseptic power, is even less irritating than boracic acid."

[418.] CRIMSON MARKING INK.—Can any of your readers oblige me with the formula for a really good crimson marking ink, one that will remain permanently crimson, without heat being applied, but on the addition of a hot iron changes to black?—Chemicus.

Pharmaceutical Education.

Sir,—Allow me to make a very short reply to your editorial comment upon my letter in last week's Journal, vide "Pharmaceutical Education."

You say I was "labouring under some misconception, in considering the attitude of the Council of the Pharmaceutical Society, twelve months ago, as antagonistic to pharmaceutical education." If so, I am pleased to be disimbued of that impression, which at that time was pretty generally shared in by others on this side of the Channel. The Select Committee appointed to investigate the Irish pharmacy question was informed that they (the Pharmaceutical Society) would give no assistance to an educational movement in Ireland, although it would be urgently required. And it was generally understood that there was a party in the Pharmaceutical Society who wished to sever the connection of their own school in London and the Pharmaceutical Society of Great Britain, although that excellent school in years past had done so much towards raising the Pharmaceutical Society to the very high position it now holds.

"Sympathy" is pleasant to receive and very easy to give, but will not always meet the exigencies of the hour, and of course will not educate the pharmaceutist in Ireland.

C. R. C. Tichborne.

Dublin, November 17, 1874.

Sir,—I have a great objection to public correspondence coloured by personal feeling, and would have preferred that my letter of Oct. 22 might rest on its own merits, but I regret that to leave the matter thus might appear to be an admission that I have a contempt for associates, which is not the case.

I have long regarded the Minor examination as the *pons asinorum* of pharmacy, and with this idea in my mind I wrote that "a man had better turn grocer than remain for life an ass of the Ph. Soc." I admit this was a rash expression, seeing that I did not mean to imply anything more than that the rejected student was, like this patient creature, condemned to fill only an inferior position; but some kind little printer's devil, willing to save me from such an error, printed it "associate." The meaning I intended to convey was that a man had better turn grocer than retain for life his connection with pharmacy, wanting the Minor qualification, being thus condemned to the ranks of assistantship, and to a low grade even of the subordinate position.

It is only in the two earlier examinations that a few hundred students have been rejected, and it is only in the early stage of a man's course that it is merciful to compel him to change his plan if he has adopted that for which he is naturally unsuited. When the student has taken his degree and become a man of business, no one would think of interfering further with his doings; but I repeat it is a pity for him as well as for the public, if after being well examined, his pharmacy becomes rusty from want of use.

Barnard Proctor.

[*** We regret having failed to perceive that the words "an Ass: of Ph. Soc." were intended to express a joke.—Ed. Ph. Journ.]

Calamine.

Sir,—Many of your readers I am glad to find have perfectly understood the kind of calamine powder which I have recommended for general use; and some have been kind enough to send me good samples prepared from the natural article, in the way I pointed out. I have no doubt the object I have in view will be in great measure secured, but I had hoped that you would have lent your aid in bringing about a common understanding as to the kind of characters of the powder most desirable for general use, so as to avoid the present uncertain results which are obtained from the employment of calamine powder of the most varied descriptions.

I still hope that you have misunderstood me, therefore, let me restate my position. After a very extensive use for many years, I have reason to be fully satisfied with the use of a particular form of a certain drug and that particular form only, as a most valuable therapeutic agent. I consequently ask pharmaceutists, in your columns, to accept the result of my experience and to adopt the use of this particular form of drug. But I am met at once by your suggestion of the employment of another preparation which I have found to be injurious or objectionable in its action, and further by the statement, contained in the editorial note you appended to my letter last week—that the use of the drug belongs more to the cosmetic art than to therapeutics, an assertion that I for my own part repudiate *in toto*. It is true I employ a powder of a particular colour, but only because it is less objectionable than others.

To proceed, however, with the main matter. Now I never knew the pharmaceutist who was not anxious to discover exactly what the physician wants in regard to the nature and character of drugs, and to meet that want. But to use plain language your dealing with the case of calamine powder, involves a distinct setting up of yourself to be the judge of what the physician ought to use. I can't think you mean this in reality, and I will not condescend to make it a personal matter. I could easily name a particular preparation or preparer in my prescriptions to save trouble to myself. But I put the matter upon much larger ground. An important benefit is to be secured the physician and the patient, and much dissatisfaction avoided so far as both are concerned by compliance with my recommendation of the use of a particular kind of calamine—a recommendation let me add made as much in the interest of the pharmaceutist as the physician—and, therefore, I finally ask you to accept such recommendation, and to assist in bringing about such a desirable result as that to which I have referred. If there has been any misunderstanding I hope this communication will remove it. Tilbury Fox.

November 23, 1874.

[*⁎* Our correspondent appears to have fallen into the error of giving a general significance to our remarks instead of regarding them as applying only within the limits we specified.—Ed. Ph. Journ.]

The Qualifications of a Good Dispenser.

Sir,—In Mr. Haselden's very able article on dispensing in last week's journal, one or two samples of foreign prescriptions are introduced; they are such as might be met with in any pharmacy in most large towns with an appreciable influx of foreigners.

Assuming they might be of interest, I beg to place at your disposal two specimens of what we have brought to us almost daily for dispensing.

The authors of these prescriptions are generally Russo-Polish quack doctors of an ancient and almost extinct school. They not only perplex the dispenser by their execrable Latin, but also by the almost *recherché* absurdity of their combinations.

With all due care in manipulation it is often impossible to turn out an elegant preparation. Asellus.

A Case for the Benevolent.

Sir,—Some time since, you kindly allowed me to make an appeal on behalf of Mrs. Newby, the widow of an aged chemist, in Brunswick Street, Hackney Road. This appeal has only produced £3 4s. 6d. Although the deceased was not a pharmaceutical chemist (and is therefore excluded by the rules of your benevolent fund), I cannot believe that your readers will willingly let his widow (who is over 60) starve—for this is the alternative if help be not speedily forthcoming, and I therefore make a special urgent appeal on her behalf. As before, subscriptions will be thankfully received for her by the Rev. Michael Kelly, St. Monica's, Hoxton, N. I have confidence that some "good Samaritans" will be found amongst your readers.

W. Bathurst Woodman, M.D.

"*Dens.*"—(1) Spontaneous oxidation. (2) In reply to this question we can only refer to the words of the article printed on pp. 253 and 254 of the Pharmaceutical Society's Calendar. If you wish for an authoritative opinion you should forward the question to the Board of Inland Revenue.

"*Elston.*"—(1) Several formulæ for Glycerine and Lime preparations have already appeared in the present series of this Journal. (2) Much would depend upon the nature of the stains. If consisting of recent grease spots they could probably be removed with a little benzol or oil of turpentine.

"*Alpha.*"—Any of the standard books on chemistry, materia medica, and botany will enable you to study the subjects of which a knowledge is required for the Major examination. A list of such works is given in the pamphlet entitled 'Hints for Students,' which may be obtained from the Secretary.

X. Y. Z.—We should think that no decomposition would take place.

J. Simpson.—A green colour for show-bottles may be prepared by dissolving two parts by weight of sulphate of copper and four parts of chloride of sodium in a sufficiency of water.

G. H.—(1) The book mentioned is, we believe, out of print; try 'Roscoe's Elementary Chemistry,' published by Macmillan. (2) Either of the works on materia medica mentioned are sufficient for the purpose.

"*Barium.*"—The information may be found in any manual of Chemistry.

J. Noad.—The bichloride of iridium is easily soluble in water; the other chlorides have a soluble and insoluble modification.

J. F.—The equivalent refers evidently to the preparation in a pharmacopœia antecedent to the British Pharmacopœia. The preparation having been before the public for many years at the time of the first issue of the latter, probably the manufacturers were loth to alter the form of the label. The apparent inconsistency would, however, be explained by the insertion of the letters, P. L.

Dr. Fever.—Tallow is bleached by treatment with bichromate of potash and sulphuric acid; a description of the process is given in Ure's Dictionary.

Communications, Letters, etc., have been received from Mr. Barnes, Mr. Simpson, Mr. Mee, "Nemo," A. P. S., R. M.

AN ADDITIONAL METHOD OF TESTING GLYCERINE.*

BY DR. RICHARD GODEFFROY.

Professor of Practical Chemistry in the Vienna School of Pharmacy.

As is known, pure glycerine should be free from colour and smell, neutral, of specific gravity 1·26 to 1·27, capable of mixing with alcohol and water in all proportions, and free from all foreign substances.

The methods published for the examination of the purity of glycerine are somewhat tedious, for the glycerine must be tested not only with regard to its specific gravity, but also by means of all possible reagents for finding out of impurities which might be present. I believe that now I have found a method by means of which some of the testing operations are much simplified.

If pure glycerine be placed in an open platinum or porcelain crucible, and heated up to 150° Celsius, it will begin to boil. It can now be ignited, and will continue to burn quietly with a blue and not very luminous flame, without diffusing the least smell or leaving behind it the least residue.

When the glycerine has a specific gravity below that of pure glycerine, it will boil under 150° Celsius, but at the moment of boiling it cannot be ignited.

If metallic salts be mixed with the glycerine they will remain as residue in the dish; the same would be the case when more highly organized combinations are present; these remain in the cup as a black, charred, or soot-like residue.

I may mention that glycerine can be ignited very easily by means of a cotton wick, and continues to burn without smell; on extinguishing the flame there is no smell. The ordinary commercial glycerine of specific gravity 1·249 to 1·256 can easily be ignited by means of cotton: it is not necessary in this mode of ignition that the glycerine be anhydrous.

[*The discussion on this paper is printed at p.* 454.]

PRESERVATIVE EFFECT OF CHLOROFORM UPON VEGETABLE INFUSIONS, ETC.†

BY J. B. BARNES, F.C.S.

Early in the course of the present year, Dr. George Pritchard, of Greenstreet, Kent, communicated to me the fact that he had found, by the addition of chloroform to vegetable infusions, they were preserved for a considerable time.

This appears a subject to which some interest is attached; therefore I have brought it before the meeting, together with the result of some experiments, which I have made to ascertain the minimum quantity of chloroform, necessary to effect the preservation of infusions and some other substances.

On the fourteenth of last month two sets of infusions of calumba, chiretta, malt, senna, and roses, were prepared; each set was marked No. 1, and No. 2, respectively. To eight fluid ounces of No. 1 of each sort were added five minims of chloroform, and to the same quantity of No. 2 three minims; they were well agitated, set aside, and examined from time to time. Those of calumba, chiretta, malt, and senna, when fresh, were tested with litmus paper; they were decidedly acid, and it does not appear that the acidity has increased. All marked No. 1 are as good now after six weeks as they were when new; they are clear, retain their natural odour, and do not appear to have changed in the least. Of those marked No. 2, the infusion of malt, after four days, had lost its agreeable odour, was turbid, and frothed considerably when agitated. After a fortnight those of calumba, chiretta, and senna, showed signs of change; they had lost their good odour, were no longer bright, and quite unfit for use, the infusion of roses alone of this set remaining good. The result is that infusions of calumba, chiretta, malt, and senna will keep good for a reasonable time by adding *five* minims of chloroform o every eight fluid ounces; and *three* minims will suffice to preserve the same quantity of infusion of roses. I have no doubt that infusions of other substances, may be preserved by the addition of chloroform in the same proportion. It will be easy to add chloroform to concentrated infusions, so that when diluted, each sixteen ounces may contain *ten* minims of chloroform. There are upon the table two samples of mucilage of acacia, marked No. 1 and No. 2; No. 1 contains chloroform in the proportion of *one* minim to the fluid ounce, and No. 2 *two* minims; they were prepared six weeks ago, and both appear to be as fresh now as they were the day they were made.

At the same time *four* minims of chloroform were added to four fluid ounces of mucilage of tragacanth, well agitated and set aside, together with some of the same mucilage without chloroform, which, when tested immediately after it was prepared, proved neutral to litmus paper. These samples were again tested a few days since, and that containing chloroform was still neutral, whilst the other had become strongly acid, and quite unfit for use.

Having been successful so far, I thought it probable that by adding chloroform in the proportion of *four* minims to the pint, elder, orange, and rose water might be prevented from throwing down the flocculent precipitate which so commonly occurs in them, but it is not so; probably it might be if added to recently prepared water. Of course in this case the delicate odours must not be overcome by the addition of too much chloroform.

The question now arises, how does chloroform effect the preservation of infusions and mucilage of acacia and tragacanth? In my opinion it preserves them by its action on the fermentable substance held in solution, and this is strengthened by the property it possesses of preventing alcoholic fermentation. About three weeks ago I mixed two fluid drachms of yeast with three separate sixteen ounces of fresh infusion of malt, which had cooled; they were marked Nos. 1, 2, and 3. To No. 1 were added *twenty* minims, and to No. 2 *ten* minims of chloroform; no chloroform was added to No. 3. They were set aside in a warm place; after a while fermentation set up in No. 2 and No. 3, with the formation of alcohol, but No. 1 remains to this day unfermented.

Not only is the alcoholic fermentation prevented by chloroform, but when added in sufficient quantity to fresh milk, the lactic fermentation is also prevented. To two eight fluid ounces of fresh milk were added

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, December 2, 1874.

† Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, December 2, 1874.

respectively *ten* and *twenty* minims of chloroform; they were kept in a warm place, and occasionally agitated; after five days had elapsed that containing *ten* minims had developed lactic acid in quantity sufficient to separate the caseine, whilst that containing *twenty* remained fresh and good. It might be found convenient to preserve milk in this manner, always taking care to boil it just before using, in order to drive off the chloroform.

It is very probable that solutions of acetate and citrate of ammonia, citric acid, lemon juice, and many other organic substances may be preserved by chloroform.

About seven years ago Dr. Pritchard informed me that he was then using chloroform water in his mixtures, much to his own satisfaction and that of his patients.

[*The discussion on this paper is printed at p.* 455.]

CHLOROFORM AS A PRESERVATIVE AGENT IN INFUSIONS.*

BY F. J. BARRETT,
Dispenser at the Wolverhampton and Staffordshire General Hospital.

Nearly four years ago, on commencing my duties at this hospital, I found that the cost of rectified spirit for the preservation of concentrated infusions formed a very serious item of drug expenditure, and twenty-five per cent. of rectified spirit could scarcely be considered (apart from its preservative action) a necessary or even desirable adjunct to a concentrated infusion, I endeavoured to discover some more economical preservative. After several experiments I hit upon *chloroform*, and found it to answer the required purpose. As I cannot place my hands upon the notes I made at the time, relative to the length of time various infusions kept good with different proportions of chloroform, compared with the same infusions treated with rectified spirit, these remarks will, I fear, be comparatively worthless.

I found subsequently, on exchanging notes with a friend, a brother hospital pharmaceutist, that there was one trifling drawback to the importance of this discovery—namely, it had been found out many years before, and was in constant use in more than one hospital. I believe, however, that no record has been published of its use for this purpose, and Mr. J. B. Barnes will doubtless do good service in calling the general attention of chemists to its important preservative properties.

The following is the *modus operandi* adopted in this hospital laboratory:—We prepare a three weeks' supply at once (generally about four gallons of concentrated infusions of quassia, calumba, and gentian, and smaller quantities of others). A Winchester quart (four pints) is first half filled with infusion, then two drachms of chloroform is poured in and well shaken for two or three minutes, then another pint of infusion is added, and again well shaken, and lastly the bottle is filled, stoppered, tied over with leather, and stored in a cool place. In this way we have kept for two months a concentrated infusion, which, upon dilution with water, will remain unchanged as long as an infusion prepared in the ordinary manner. Certainly, there can be no possible objection to chloroform thus used, as one ounce of diluted infusion would only contain one-sixth of a minim of chloroform.

In making concentrated infusions containing volatile aromatics, we evaporate a simple infusion of the active ingredient by a steam bath to an eighth part of its bulk, and then infuse the aromatic substances in this till cold.

Besides using chloroform as a preservative in infusions, I have more recently used it combined with glycerine in place of rectified spirit, in the preparation of such fluid extracts as ergot, bael, liquorice, cinchona, greater periwinkle (*Vinca major*), and others. Very satisfactory preparations may be made in this way, which if not quite as elegant in appearance as the Pharmacopœia extracts, are at least much more economical and certainly as active, which, after all, in hospital work are the main points to be considered. We have some ergot extract now in use, which was made in July, and it appears to be quite as good as when first manufactured. I hope shortly to be able to send to the Journal full particulars of the way in which we prepare our liquid extracts.

Doubtless chloroform could be used most advantageously in many preparations in the place of rectified spirit, and it has the advantage when greatly diluted of being exceedingly palatable, so that it would not be objected to by the patient.

EXTRACTUM GLYCYRRHIZÆ LIQUIDUM.*

BY CHARLES UMNEY.

At the evening meeting of this Society in April last, when the British Pharmacopœia Addendum, and its preparations, were under discussion (*Pharm. Journ.*, April 4, 1874), when speaking of the Fluid Extract of Liquorice, I questioned if the 11 per cent. of rectified spirit ordered to be present in the completed product was sufficient for its proper preservation.

About that time I set aside a pint of the fluid extract (in a cool room) in order to note any change that might take place.

Upon examination after some three or four months, I found the contents in a state of fermentation, which seemed to be progressing on each occasion I opened the bottle.

This week I found that not only was there fermentation, but a considerable yellow deposit, and in addition a partial gelatinization extending to almost half its volume.

I have not examined the deposit, but I should imagine that it is chiefly glycyrrhizin deposited by the action of the acid produced in the fluid extract by the fermentation of glucose, or other body capable of vinous fermentation, existing in the liquorice root with the glycyrrhizin, which itself is not susceptible of fermentation. Fluid extract of liquorice is a very desirable preparation; the process given in the Addendum for its production is thoroughly sound in principle; but its preservation can, without doubt, be improved upon.

Whether an increased quantity of alcohol is desirable, or a trial of glycerine or other preservative fluid, I am not prepared at the present moment to say.

I have, however, put aside several specimens in order to determine this point.

[*The discussion on this paper is printed at p.* 456.]

ADULTERATION OF BEESWAX.*

BY ADOLPH W. MILLER, M.D., PH.D.

For a year or two past there has been offered in the United States market, and most probably elsewhere, an article termed "refined beeswax." It is unusually handsome in appearance, and is generally represented as being strictly pure. It may be known by all of it being of a uniform bright yellow colour, entirely free from the sedimentary stratum of impurities ordinarily found in country wax. Its surface is clean and glossy, having no foreign particles adhering to it.

The melting point of the refined wax was found by the author to be 146° F., that of pure wax being 156°, and that of paraffin from 137° to 140°. Its specific gravity is ·929, placing it again intermediate between beeswax, ·963, and paraffin, ·871. Being thus induced to suspect the presence of the latter body, he heated 100 grains of the refined article for fifteen or twenty minutes with one ounce of sulphuric acid to about 350° F., several ounces of water were then added, and, after cooling, a sheet of paraffin weighing 80 grains was obtained, the loss representing the beeswax which had been carbonized by the acid. In order to verify the experiment, it was repeated with a composition of four parts paraffin to one of wax, when analogous results were obtained. One hundred grains of pure paraffin, treated in the same manner, were recovered unchanged.

The only difficulty in the test is the separation of the carbonaceous matter from the paraffin. This is most conveniently removed by repeatedly melting the paraffin on water, at the same time gently stirring it.

There seems to be a considerable difference in the mode of contraction, while cooling, between beeswax and paraffin, and this may serve to detect the adulteration, at least when practised to this extent. Blocks of paraffin are decidedly concave on the top, and the specimens of adulterated wax were observed to be more or less concave on top in proportion to the amount of paraffin which they contained. Pure beeswax appeared to be level, the contraction acting in a horizontal direction and tending rather to the production of vertical fissures.

The optical behaviour is also different; pure wax is quite opaque, while this adulterated article is somewhat translucent, more particularly on the edges.

SOCIETY OF PUBLIC ANALYSTS.

A general meeting of the members of this Society was held on Tuesday, December 1st, at the City Terminus Hotel, Cannon Street, under the presidency of Professor Redwood.

The minutes of the previous meeting were read by the Secretary. A brief report was presented, stating what had been done by the Provisional Committee appointed at the inaugural meeting in August last, from which it appeared that the actual number of original members of the Society is now 63, only about 15 public analysts throughout the kingdom having failed to avail themselves of the opportunity of joining without election. Since the beginning of October, ten meetings had been held, the principal business transacted being the drawing up of a constitution for the Society, and the framing of a definition of adulteration which should be at once comprehensive enough to include all actual adulterations, and at the same time sufficiently elastic to prevent oppression or injustice. To this end a great number of proposed definitions, submitted by some of the most eminent chemists in the kingdom, had been carefully considered and digested, and they had also been laid before some experienced solicitors connected with local authorities, whose legal experience, it was thought, would be valuable. The result had been circulated amongst the members in a printed form, but several suggestions had been received since, which appeared worthy of consideration before the proposed definition was adopted. The remainder of the report referred to the election of officers for the ensuing year, and the financial arrangements of the Society; also to a contemplated arrangement with the publisher of an established scientific journal for the use of a certain portion of space periodically in the interests of the Society.

Mr. Wigner stated that he had received letters from many gentlemen throughout the kingdom, whose names he read, approving the objects of the Society, and regretting they were not able to attend.

Dr. Tripe proposed the adoption of the report, which was seconded by Mr. G. Turner, of Landport.

Mr. Rimmington said he doubted whether it would be wise for them at present to propose for the adoption of Government any definition of adulteration. He feared whatever they might do would only be subject to criticism, and might very likely be pulled to pieces without producing any useful result.

The Chairman said he thought the discussion on this point had better be raised later, when the proposed definition was brought forward; and the report was then unanimously adopted.

The Chairman then introduced the main business of the meeting, viz., the formation of a constitution for the Society. A printed copy of the one framed by the Committee had been circulated amongst the members, and its adoption he begged leave to move, being pleased to add that no alterations whatever had been suggested in it, though such had been invited.

Mr. Wigner then proceeded to read the suggested constitution and rules, in the course of which Dr. Tripe suggested that the number of honorary members should be limited; and in answer to the same gentleman, the Chairman explained the manner in which the votes would be taken. The objects of the Society were stated to be as follows:—

"1. To promote and maintain the efficiency of the laws relating to adulteration.

"2. To promote, and as far as possible to secure, the appointment of competent public analysts.

"3. To improve the processes for the detection and quantitative estimation of adulterations, and to secure uniformity in the statement of the results by holding periodical meetings for the reading and discussion of original papers on chemical and microscopical analysis, especially with reference to the detection of adulteration."

According to the proposed constitution, the Society will consist of members, honorary members, and associates, the members, in addition to public analysts, being analysts in actual practice, and the associates assistants of analysts, etc. A candidate for admission must be recommended in writing by four members, two of whom must testify to his fitness from personal knowledge. The election is to be conducted by means of voting papers, which may be forwarded by post; three-fourths of the votes, of not less than twelve members, being necessary for election. Members will pay an admission fee of one guinea and an annual subscription of one guinea; associates will pay an annual subscription of five shillings, and be elected for a period of three years only, at the expiration of which time they may be again recommended for election. The affairs of the Society are to be managed by a Council consisting of the President, two Vice-Presidents, the Treasurer, two Honorary Secretaries, and not more than six other members.

A brief discussion arose as to whether membership was open to all analytical chemists, whether public analysts or not, and the Secretary read the resolution passed at the former meeting, showing that this was the intention of the meeting.

The next point on which a difference of opinion arose was on Dr. Tripe's proposal to limit the number of honorary members, and on a vote being taken, it was decided by 11 to 3 that the number should not exceed twelve. With one or two verbal alterations and the addition of a provision for summoning extraordinary

* From the *American Journ. Pharmacy* for November.

general meetings on a requisition signed by eight members, the rules as printed were adopted on the motion of the Chairman, seconded by Mr. Wanklyn.

Mr. Cleaver and Mr. Piesse were appointed scrutineers to examine the balloting papers for the Council and officers of the Society, and whilst they were so engaged,

Dr. Tripe moved a vote of thanks to the Committee for their past labours, which was seconded by Dr. Muter, carried unanimously, and briefly acknowledged by the Chairman.

Mr. A. H. Allen drew attention to a compilation and classification of the evidence taken before the Adulteration Act Committee of the House of Commons during the last session, circulated semi-privately, he believed, by some gentlemen connected with the Grocers' Association, and read several questions and answers from the compilation referred to, which differed entirely from the authorized report as appearing in the Blue Book.

Mr. Estcourt (Manchester) also spoke of having noticed similar errors, some of which seemed to arise from something worse than carelessness.

The result of the scrutiny showed that the Council and officers proposed by the Committee had been elected by a large majority; the names being as follow:—

President, Professor Theophilus Redwood, Ph.D.; Vice-Presidents, A. H. Hassall, M.D., and J. A. Wanklyn, M.R.C.S.; Honorary Secretaries, C. Heisch and G. W. Wigner; Treasurer, T. Stevenson, M.D.; other Members of Council, Messrs. Allen, A. J. Bernays, C. Estcourt, G. A. Rogers, M.R.C.S., F. Sutton, and J. W. Tripe, M.D.

Mr. F. Sutton (Norwich) moved that the annual meeting of the Society should be held on the first Tuesday in the month of February each year, that the ordinary meetings should be held on the first Tuesday in the months of March, May, and November, and that a provincial meeting should take place in August or September.

Mr. Rimmington seconded the motion.

Mr. Allen suggested that the first week in the several months named be chosen, but that the day be left open. After some conversation, this was agreed to, and the resolution was passed unanimously.

A resolution having been passed for the immediate payment of a subscription in order to defray the necessary preliminary expenses, the meeting adjourned for refreshments.

A few interesting novelties in analytical appliances were shown in the refreshment-room.

On resuming business,

The Chairman said the next question for discussion was the definition of adulteration; a very important subject, which would be introduced by Mr. Heisch.

Mr. Heisch said the definition proposed had been already circulated amongst the members, and he hoped had been carefully considered; to show how far it was intended to be definitely adopted, he would read the resolution, which he should conclude by moving, viz.:—

"That the following having been unanimously agreed to by the Committee appointed for the purpose, is considered by this meeting as a fair definition of an adulterated article, and they recommend it to the Council of the Society as one which may advantageously be *adopted as a guide*."

The definition was as follows:—

Proposed Definition.

An article shall be deemed to be adulterated:—

A. In the case of food or drink:—

1. If it contain any ingredient which may render such article injurious to the health of a consumer.
2. If it contain any substance that sensibly increases its weight, bulk, or strength, unless the presence of such substance be due to circumstances necessarily appertaining to its collection or manufacture, or be necessary for its preservation, or be acknowledged at the time of sale.
3. If any important constituent has been wholly or in part abstracted, without acknowledgment being made at the time of sale.
4. If it be a colourable imitation of, or be sold under the name of, another article.

B. In the case of drugs:—

1. If when retailed for medicinal purposes under a name recognized in the British Pharmacopœia, it be not equal in strength and purity to the standard laid down in that work.
2. If when sold under a name not recognized in the British Pharmacopœia, it differ materially from the professed standard.

Proposed standards or limits for milk, skim-milk, butter, tea, cocoa, and vinegar were then given.

In the first place it would be observed that the Committee had not quite followed the instructions given them to draw up a definition of adulteration, but, acting under what they believed sound legal advice, they had endeavoured to lay down what should constitute an adulterated article, leaving it open for other things to be considered adulterated or not, in the discretion of analysts and magistrates. Instead, therefore, of attempting to define adulteration in the abstract, they had said such and such things should be deemed to constitute an article adulterated, though not saying that nothing was to be considered unadulterated which did not come under those conditions. The Committee had had before it a definition much more sweeping than that now adopted, and he had at first been inclined to support it; but on consideration it was found that a schedule of exceptions to it would have been required, and it was ultimately rejected on that ground, though even the present one was not quite free from the same objection. It was in his view very important to bear in mind the distinction between defining adulteration, and saying that certain things should be considered adulterated; because the latter left more discretion to analysts, and also to magistrates, who would in many instances be the final judges whether an article was adulterated or not. It had been found desirable to distinguish between drugs and articles of food or drink, and also to avoid the use of the word "add" in any shape. The Act was intended not only to protect the public health, but also to prevent imposition, and whether the adulteration arose from wilful fraud or from ignorance or carelessness on the part of the dealer, he believed the public were equally entitled to protection. The question of fraudulent intent would no doubt be considered by the magistrate in imposing the penalty; but such matters did not come properly within the scope of the analyst's functions, and they had therefore omitted any such words as either "add" or "fraudulently," simply defining an article to be adulterated if it contain such and such ingredients, or did not contain a sufficient proportion of certain others. Having read the definition as above given, he suggested that clause A. 4 might be added to B., and concluded by moving the resolution.

Dr. Dupré having seconded it, *pro formâ*,

Mr. Wigner read the various suggestions which had been received, the most important of which were, the addition of the words "foreign" in clauses 1 and 2, and the substitution of "fraudulent" for "colourable," in clause 4.

Dr. Dupré said these definitions, although not put forward as final, had not been adopted without very mature consideration, and after repeated discussion of a great many suggestions, most if not all of which had been either adopted or distinctly rejected after examination. Indeed, many suggestions which at first sight seemed very reasonable, appeared on further consideration totally inadmissible. Thus, the Committee had unanimously come to the conclusion that this was so with regard to the insertion of any such word as "fraudulently" or "wilfully," because it was hardly ever possible to prove a fraudulent intention, and the introduction of such words would practically render the Act a dead letter. Such points might very properly be considered by the magistrates, but had no place in a definition of adulteration, as applied to the article. Their object had been to make the definition sufficiently comprehensive to ensure the conviction of any one who so far tampered with any article as to make it injurious either to the health or pocket of the customer; but they had not found it practicable so to frame it as to include certain fancy articles, as they might be termed, which contained only an infinitely small amount of certain ingredients, and, if it had been practicable, he did not know that it would have been desirable. On the other hand, they desired to make their definition so elastic that it should not interfere unnecessarily or unfairly with the manufacturer or vendor. The proposal to add the word "foreign" to the first clause had been made in several quarters, but it had been distinctly rejected by the Committee, because its insertion would practically render it almost impossible to secure a conviction, there being such a vast number of ingredients present in very minute quantities, that it would often be difficult to convince a magistrate that the adulterant was really foreign to the substance, and that it had been improperly added. Objections had been taken to clause 1 that a teetotal analyst might be induced under it to certify that wine or beer was adulterated because it contained alcohol, which *he* deemed injurious to health; but this danger he thought entirely visionary. The insertion of the word "foreign" in clause 2 would be even more objectionable than in clause 1, and it might lead to great difficulty in the case of adulteration of milk with water; he suggested, however, that it would be improved by adding after the words "weight, bulk, or strength," the words "*or materially alters its apparent quality.*" The addition of alum to bread, or of Cayenne pepper to gin, unless in considerable quantities, could not be considered injurious to health, nor did it add to the weight or bulk, but it gave a deceptive appearance or flavour. The word "colourable" in clause 4 he thought might with advantage be omitted altogether. He was sure the Council would welcome any further suggestions, and he would urge the meeting not to come to any absolute decision upon the matter, but simply refer the matter back to the Council for final revision.

Mr. Sutton asked if it was intended to hand in this definition to the chairman of the Local Government Board, the advisability of which he much doubted.

Mr. Wigner said that was the ultimate intention, no doubt, but not at the present stage.

Mr. Sutton said there appeared to be a great difficulty in fixing upon a definition which would meet the views of everybody, even amongst themselves, and still less the views of magistrates who had to administer the law; therefore, until they were asked for it, he did not think they should volunteer one to the Government. He had no doubt that any fresh bill which might be prepared would be so framed as to cover all things which it was considered desirable to prohibit, and then probably the analysts would be asked for information on matters coming within their own province. His own opinion was that some of their brethren had been much too particular, had drawn the line too stringently, and had not sufficiently considered the difficulties with which traders had to contend. If this sort of thing were pushed too far it would produce a spirit of antagonism which would result in no good to anybody. His experience was that the public really cared very little what they ate or drank, for there was hardly a case to be found in which the prosecution had not been initiated by the officers appointed under the Act.

Mr. Rimmington agreed with Mr. Sutton, and thought they would make a great mistake in drawing up a definition which should either be handed to the Government or made public in any way.

Mr. Piesse begged to differ *in toto* from the last two speakers. In his opinion both the public and the analysts would benefit greatly by a definition being drawn up on a subject upon which the greatest ignorance generally prevailed.

Dr. Stevenson thought they would follow the wisest course in leaving this matter to the ultimate decision of the Council, though he saw no possible objection to the publication of the definition as at present framed. If they were as a body to ask for any alteration in the existing law, there could be no doubt they would be asked to state what their idea of adulteration was, and though they might not have framed their definition in strictly legal language, they ought to be in a position to state in plain English what their view of the question was. This definition was the product of a vast amount of labour and inquiry in all quarters, and he thought they could not do better than refer it back to the Council with their general approval.

Dr. Tripe thought their course was quite clear. In the infancy of the Society they should not go before the public saying this or that is our definition of adulteration, but they should lay down something for their own guidance, so as to secure unanimity amongst themselves. The proper course, therefore, was to refer the matter back to the Council, as had been proposed.

Mr. Wanklyn said they must face the question before them. To refer back these definitions to the Council was to provisionally adopt them, and he certainly could not see that they would be going too far in so doing. With regard to the clauses under section A., they had simply adhered to the Act as it stood and was being interpreted by the magistrates. A man was to be punished if he poisoned any article of food or drink, or if he diminished its value and cheated his customer, and these ideas were here carried out. He quite agreed in the remarks which had been made as to the impropriety of introducing the word "foreign," which would often prevent a conviction where it ought to be obtained, and also approved of the omission of the word "colourable."

Mr. Allen remarked that few gentlemen present probably were aware of the immense amount of labour which had been bestowed upon the framing of this definition. The Committee had obtained some twenty definitions from the leading chemists of the kingdom, and then having procured a list of the most frequent adulterations, had compared them, *seriatim*, with the definitions, to see which most fully met the case; they had then been revised by independent persons, and legal opinions also had been obtained. He himself had come up to London six times since the end of September on the matter, and others had spent an equal amount of time and trouble upon it. He did not think the Government would be able to deal with the question in so thorough a manner. He still thought the phraseology capable of improvement, though he had been pretty well convinced, contrary to his previous impression, that the insertion of the word "foreign" would be a mistake.

Mr. Rimmington, having read a definition which he had drawn up, containing the words, "the same being done covertly to defraud and deceive the purchaser,"

Mr. Heisch said that would be making the analyst judge and jury. They had decidedly come to the conclusion not to meddle with the question of intention.

Mr. Rimmington thought it was necessary to show the intention in order to prove adulteration.

Dr. Tripe said unfortunately his first two cases broke down on that very ground, but on fresh summonses being granted under section 2, instead of section 3, convictions were obtained.

Mr. Wigner said he would read the opinion of a legal gentleman on this very point. He said, "How is it to be determined that water in butter has been *fraudulently* added or retained by the retailer?"

Mr. Rimmington said it was to be determined by inference.

Dr. Stevenson said he had had some cases break down on the question of *fraud*, and practically it was found useless to take out a summons under that section. The personal imputation was so great that hardly any local Board would prosecute, and magistrates would admit every possible excuse rather than convict; whereas if it was simply a question of adulteration, a conviction was readily obtained, and very rightly in many cases. The old Act of 1860 was an illustration of this, for it remained a dead letter.

Mr. Wanklyn remarked that it was evident their duties were much simplified by the tacit admission of the magistrates, that persons who sold goods were bound to understand what they were dealing in. They had simply to testify as to the quality of the article, and, if it was not what it should be, the trader must suffer the consequences of his ignorance or carelessness.

Dr. Muter said it was evident to all who knew anything about the working of the Act, that it would break down if fraudulent intent had to be proved. He was concerned in the first case ever brought under the Act, which was withdrawn on that ground under the advice of Mr. Poland. He thought the definition a very good one.

Mr. Sutton wished it to be understood that he cordially approved of the definition for their own use, though he doubted the wisdom of too hastily publishing it or laying it before the Government.

The Chairman said he should like to make one or two remarks before putting the motion. In the first place, he thought it was very desirable, as had been so well explained to the meeting, that they should arrive as near as possible to a clear conception of what they thought would be a fair definition of an adulterated article. Having taken part in the discussions on this subject, and the more it was discussed the better, instead of becoming more confident in their ability to make, in every respect, a good, comprehensive, and explicit definition, he became more and more doubtful as to its possibility. In several respects his opinion had materially changed since he commenced looking at the question, and he regretted that even at the present time he was unable to entirely agree with the definition now put forward. He believed he had been the principal dissentient in the Committee, having entertained serious doubts from the first as to whether they had framed such a definition as it would be desirable to lay before the public. However, the resolution as proposed had avoided this difficulty, because they did not propose that the Society should be strictly tied down to the definition now brought forward; but all agreed in this, that it was desirable they should indicate as far as possible, in intelligible terms, what were the conditions under which articles should be looked upon as adulterated. He was not quite satisfied, and did not think he ever should be, with this amount of success, because if they were to have a definition, he, for one, desired one which should cover all articles which could be considered as adulterated, and if they fell short of this, and found they could not frame a definition which would be so comprehensive as to take in everything, but at the same time elastic enough for purposes of commerce and manufacture, he should be inclined to come to the conclusion that they had better not have one at all, but simply depend upon the Act itself, which specified in so many words that if an article were adulterated in whatever way, not defining what that way should be, the seller was subject to a penalty. It was quite possible they might come to that conclusion at last, but he had originally entertained a strong opinion that without much difficulty they might frame a definition which would be both stringent enough on the one hand, and elastic enough on the other, to cover all cases which they required to take cognizance of. At the same time he must confess that the more he looked into the subject the more difficulties he saw. He thought, however, they would show a great amount of weakness if, as a body, they drew back from the attempt to do all that could be done towards defining what constituted an adulterated article. He hoped they would endeavour to do this, but their first object must be to do it for their own use, so that they might be able to agree amongst themselves, and further be in a position to enlighten the public upon the matter; but they must not decide too hastily what use to make of the definition when accomplished. The one now proposed was framed in popular rather than in strictly legal or technical language, but it gave a very good general idea of what was intended, and if the Society agreed to the resolution which had been proposed, that it should be sent back to the Council for further consideration, he thought that would be the best course that could be adopted. The motion was then put and carried unanimously.

Section B., the discussion of which had been postponed until after Section A. had been disposed of, was next brought forward, when

Dr. Tripe proposed that in clause 2 the words "or its synonym" should be added.

Mr. Rimmington said he doubted very much, with regard to many popular medicinal agents, whether it was not better for the purpose the more they were adulterated. Take, for instance, such articles as laudanum or sweet spirit of nitre. He believed, if they were sold of the pharmaceutical strength, there would very soon be a great many inquests required. In his part of the country persons were in the habit of taking sweet spirit of nitre by the ounce or half-ounce, and they would have great difficulty in convincing ignorant persons that they only ought to take a teaspoonful. The same thing with regard to spirit; he thought the more water there was in it the better.

Dr. Tripe could not understand what the "professed standard" meant.

The Chairman said the name of the article, or the label affixed to it, might imply a standard. With regard to articles of medicine, not comprised in the Pharmacopœia, there was a generally recognized composition which would be the professed standard.

Mr. Wigner said if an article had no synonym it would be shut out altogether; and this was the case with many articles, such, for instance, as milk of sulphur.

Dr. Tripe said milk of sulphur was the synonym for precipitated sulphur, according to Garrod.

Dr. Stevenson said the professed standard did not mean that of the Pharmacopœia, but it meant that when the article referred to was something which had either an acknowledged standard as being a natural product, or was generally known as of a certain composition, it should come up to that standard. It would introduce a great amount of confusion in the definition if they adopted the word "synonym," because there were many articles which, though approximating to the preparations in the British Pharmacopœia, had no synonyms, strictly speaking. Milk of sulphur, for instance, was a recognized substance known to chemists as distinct from the substance known as precipitated sulphur, having long been prepared in a different manner. Paregoric, again, was not the same as compound tincture of camphor, which latter was really an imitation of paregoric. Of course if any article were the true synonym of one in the Pharmacopœia, the Pharmacopœia standard would be applied to it.

Dr. Tripe said he would withdraw his suggestion.

Mr. Piesse suggested the substitution of the word "its" for "the" before "professed standard," and a similar resolution to the last was then unanimously adopted with regard to section B. A somewhat lengthy discussion then ensued as to the latter part of the definition, and the proposed standards.

Various suggestions were made by members as to some of the details therein contained, and facts narrated as to the working of the Adulteration Act, particularly with regard to the sale of milk; ultimately a similar resolution recommending these standards to the Council for their guidance was adopted, but with the understanding that the word "limits" should be substituted for "standards." A vote of thanks to the chairman concluded the proceedings which had lasted over four hours.

The Pharmaceutical Journal.

CHEMISTS AND THE ADULTERATION ACT.

WE are glad to notice that marked progress is being made towards the establishment of an organization which we have long pointed to as being a pressing desideratum, viz., a department of public chemistry. The appointment of official analysts, under the Adulteration Act, has contributed largely towards the realization of this object, and it is satisfactory to observe that those who hold this position are now associating themselves together for the purpose of mutual conference, and consideration as to the nature of the duties they have to perform, and the mode in which those duties should be carried out.

So far, it must be admitted that the promoters of the "Society of Public Analysts" are entitled to the thanks, not only of the public generally, but also of all those who are in any way affected by the operation of the Adulteration Acts, and as chemists and druggists may be liable to be so affected in many respects, we have thought it desirable to place before our readers a report of the proceedings at the meeting which took place on Tuesday last. From that report it will be seen that the constitution framed by the Provisional Committee since the inaugural meeting, last August, was in the main adopted by the meeting, that officers and a Council were appointed to conduct the business of the Society, and arrangements were made for periodical meetings, etc.

We also learn from the report that much time has been devoted by the Provisional Committee to the framing of definitions of adulteration, which should be at once comprehensive enough to include all actual adulterations, and at the same time sufficiently elastic to prevent oppression or injustice. We can well understand that this endeavour has been a work of considerable labour, and we fully recognize the propriety of such an inquiry being undertaken by public analysts, individually or collectively, as relating to a matter of special importance for them to consider; but we have grave doubts as to the policy of the attempt, on the part of public analysts, to lay down authoritative definitions of adulteration, inasmuch as this involves the consideration of many facts from other points of view besides that of the chemist.

In this respect we are somewhat apprehensive that the activity of the public analysts is likely to overstep the legitimate limits of their functions; for though some who hold that office would doubtless be capable of rendering valuable service in the determination of many questions that have arisen, or are likely to arise, in the application of the Adulteration Acts, it seems that such services might be more gracefully rendered on the requisition of the legislature than by volunteer action on the part of the analysts.

That this is the case will, we think, be sufficiently evident from the diversity of opinions expressed by the several speakers in the discussion of the proposed definitions, and from the result actually arrived at of referring the matter of definitions back to the Council for further consideration. For our own part, we are disposed to regard the the definitions in Section A. (see page 444) as being more calculated to raise difficult and disputable questions than to serve as a guide or assistance to magistrates who have occasion to try cases of alleged adulteration. Thus, for instance, in the very first definition it is stated that an article shall be deemed to be adulterated when it contains any ingredient which may render such article *injurious to the health of a consumer*. The words we have put in italics raise questions that are not only wholly outside the office of the analyst; but, as matters very often more of opinion than of fact, are also susceptible of being viewed very differently by different authorities and under diverse circumstances. The want of precision here referred to is no less than that in the wording of the Act itself, for though we know that Act was passed for the purpose of repressing the practice of adulterating articles of food and drink to the great hurt of the health and danger to the lives of Her Majesty's subjects, experience of its working has afforded too many illustrations of its greater capability to perplex magistrates than to protect the public. We are decidedly of opinion that no good can be effected by any such mere paraphrase of the intent of the Act as this first definition.

In regard to the second definition in this section, there is not only a total absence of any indication as to what proportion of "substance that sensibly increases" the weight, bulk, or strength of an article is to be admissible, as in the case of mustard, cocoa, etc., or beyond what quantitative limit such acknowledged and declared admixture is to be regarded as constituting adulteration; but it would also, we think, often give rise to questions whether, in reference to quantity, substances whose presence in certain articles is "due to circumstances necessarily appertaining to their collection or manufacture" are to be attributed wholly or only in part to such legitimate origin. The third definition, though relating to a noteworthy case of fraud, viz., debasement of articles, has, in our opinion, nothing to do with adulteration, except to mystify and confuse the signification of the term, and the same may be said of the fourth definition in this section, relating to fraudulent substitution of one thing for another, such, for instance, as the sale of chicory for coffee, which cannot, with reasonable regard for the utility of language, be regarded as a case of adulteration.

The definitions relating to drugs, in section B., are, if anything, more faulty and defective than those relating to food and drink; but we do not think it is necessary to point out these shortcomings to our readers.

Altogether these proposed definitions appear to reflect in a great measure the defects of the Adulteration Acts themselves, and to show the necessity of further thorough consideration of the subject of adulteration by the legislature, aided by competent and impartial advisers as to the numerous technical questions involved. Whether or not we may hope for such a consummation in the interest, not only of the public but also of the honest tradesman, is a question that the future must answer, as it must determine whether it be possible for a Committee of the House of Commons to override, on the one hand, the influences of trade interest, and, on the other, the contagion of exaggerated panic.

PRACTICAL AND THEORETICAL EXAMINING.

In a letter to the medical journals, Dr. Crisp has supplied an interesting addition to the biography of the late Dr. Lankester, as well as a valuable contribution towards estimating the relative values of practical and theoretical examinations. He says that when Dr. Lankester presented himself at the College of Physicians for examination for the licence, he had obtained honours in ten of the classes at University College, and six years previously had passed the examination for the extra licence of the College, which gave him the right to practice as a physician seven miles out of London He thought, therefore, that he would only have to undergo one examination in which he would be expected to answer practical questions. Dr. Lankester, however, was rejected, notwithstanding that one of his examiners had six years previously testified to his competency to fill creditably the office of Physician to a London Dispensary. The opinion of Dr. Lankester upon his rejection is expressed in the following passage from a pamphlet published by him :—

"If I were a young man who had only had the five years' study which the College requires, I might consistently have been sent back for a year ; but what must be thought of the value of the College examination which supposes that the knowledge it requires may be got up in twelve months, but could not be gained by eighteen years of hard study and diligent observation? At the same time, however, I am not ignorant of the fact that there are gentlemen in London who in less than a year would engage to prepare me, as they have done hundreds of other members of the College, in such a manner as to ensure my passing their examinations. I have never, however, condescended to the practice of cramming in the four examinations that I had previously submitted and passed. I conscientiously regard myself at this moment as fitted to practice my profession, and if the College examinations are of a nature rather to test the schoolboy's qualifications which may be got up by a cram than those which have been gained by reading and experience at the bedside, I can only express my regret that public confidence should have been given to examinations which every member of the College must feel are not worthy of it."

MILITARY PHYSIC.—A CURE FOR SCURVY.

General Sheridan's name is pretty widely known as that of an able officer in the United States military service, but probably few are aware that he gained his first laurels in combating disease. The *Pall Mall Gazette* states that when a young officer he was in charge of an isolated post in Texas, where scurvy in a serious form attacked the men under his command. No lime juice or vegetables were to be had; but Sheridan had heard that the juice of the Mexican agave had antiscorbutic properties. He therefore organized an expedition to search for the plant, and a grove of it being discovered about a hundred miles distant, a supply of it was procured, the juice expressed, and the men compelled, not without many wry faces and some protests, to take it in liberal doses. But the military doctor and pharmacist was successful, and from that time the disease was effectually stayed.

THE EXCISE AND THE SALE OF "BITTERS."

An influential meeting of the chemists and druggists of Hull was held on the 24th ult., to take into consideration the fact that an Excise prosecution had been instituted against one of their number, for selling, without a spirit licence, a compound, known as "Pick-me-Up," or "Morning Tonic." In the opinion of the meeting, the compound is a medicinal tincture, being a modification of the Compound Tincture of Gentian of the Pharmacopœia, which has, under various names, been openly and generally sold by the trade for many years as a tonic. The commencement of such a prosecution, without previous notice, was therefore thought to be a harsh and oppressive proceeding, and a resolution was passed requesting the Committee of the Hull Chemists' Association "to take such steps, in the general interests of the trade, as they may deem necessary, in defending the case and obtaining a clear definition of the law upon the subject." We have been informed that the case comes on for hearing on Tuesday next.

ACCLIMATIZATION OF MEDICAL PLANTS.

In a report upon the attempted naturalization of various plants at Nismes, in the South of France, furnished by M. Maumenet to the *Bulletin de la Société d'Acclimatation*, it is stated that the Japan wax tree (*Rhus succedanea*) has lasted through six seasons, though it has been cut to the ground by the frost more than once. The *Laurus camphora*, after giving hopes, has proved too tender. *Andropogon squarrosus*, an exceedingly fragrant grass, has withstood the most severe seasons. All attempts to naturalize the *Eucalyptus globulus*, however, have failed.

Professor Attfield has been elected Honorary Member of the Pharmaceutical Society of Victoria, "in consideration of great and unwearied efforts in the cause of pharmacy."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, December 2, 1874.

MR. T. H. HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Brown, Frazer, Greenish, Hampson, Owen, Radley, Rimmington, Robbins, Sandford, Savage, Schacht, Stoddart, and Sutton.

The minutes of the previous meeting were read and confirmed.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Adams, William ....Barnstaple.
Stamps, Frederick..................West Bromwich.

Elections.

ASSOCIATES.

The following having passed the Minor Examination, were elected "Associates" of the Society:—

Farquhar, James ....Aberdeen.
Simpson, Charles Alfred ....Fenton.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination were elected "Apprentices or Students" of the Society:—

Eunson, John ....Kirkwall.
Jones, W. Thomas..................Merthyr.
Stukeley, Edward Charles ......Gloucester.

An Associate of the Society was restored to his former status upon payment of the current year's subscription, and a fine of half-a-guinea.

The following names were ordered to be restored to the Register of Chemists and Druggists:—

Theophilus Challener............Aldridge Road, Perry Barr, near Birmingham.
George Edward Wood ....60, City Road, Hulme, Manchester.
Henry Hick ....1, Annakins Court, Blake Street, York.

Finance.

The report of this Committee was received, recommending the payment of various accounts, and the acceptance of estimates from Messrs. Butler & Tanner for printing the Calendar and Register for 1875. The report and recommendations were adopted.

Library, Museum, and Laboratory.

The report of this Committee stated that the following books were recommended to be purchased:—

'Phillips' Metallurgy.'
'Brown's Manual of Botany.'
'Flückiger and Hanbury's Pharmacographia.'
'Steudel's Nomenclator Botanicus.'
'Spottiswoode's Polarization of Light.'
'Beale's How to Work with the Microscope.'

The Librarian had prepared a list of duplicate books which had been ordered to be sent to the Secretary of the North British Branch, in order that, if desired, the spare copies might be forwarded to Edinburgh. The average attendance in the library during the month had been, during the day, 14; in the evening, 8. The number of books circulated had been 124 in London, 27 in the country.

The Curator had reported that the first portion of the museum catalogue was now ready for the printer. He also presented a list of duplicate materia medica specimens, which he suggested might be sent to the North British Branch. Three specimens of vegetable products, from Burmah, had been received from the India Museum for the Society's Museum.

Professor Attfield had reported that there had been 53 entries in the laboratory since the commencement of the session, and that 49 students were now working.

The report was received and adopted.

Provincial Education.

This Committee reported that it had held a meeting at which it was agreed to recommend that an application from the Manchester Chemists and Druggists' Association and School of Pharmacy for a grant of £50 be acceded to.

Mr. Robbins moved the adoption of the report, which was seconded by Mr. Owen.

The Vice-President said he had not been able to attend the meeting of the Committee on the previous evening, and he thought it would be more satisfactory to the Council at large if Mr. Brown would state the grounds on which he had induced the Committee to recommend so large a grant to one place. If the money were granted, he had no doubt there would be at least twenty other places which would have an equal right to a similar sum. The money was required, he believed, to supplement the payment to lecturers, and therefore it would be wanted in successive years, and the Council must be prepared for similar applications in future. He would not move any amendment at present, because he simply asked for further information.

Mr. Schacht thought it right, as a member of the Committee who had made the recommendation, to reply to the question just put. The Committee considered that the Manchester Society had for a great many years been making considerable efforts in the direction of pharmaceutical education; that they had more or less succeeded, with a great deal of sacrifice and expenditure not only of time, but of personal energy, in carrying out their scheme. Since 1868, they had done so without any extraneous aid, but it appeared that their arrangements now required increased outlay for the remuneration of the lecturers; and though they wanted nothing for rent of premises, library, or appliances, all these expenses having been met by local effort, they required assistance to meet the cost of the lectures. It was shown that the scheme was a particularly good one, specially adapted to the wants of their own students. Looked at merely as an experiment, it would be a wise thing to aid it, and they were not placed in this position, inasmuch as the machinery had been in operation for some time, and had been attended with very satisfactory results. True, he thought a more numerous students' list might have been shown, but the instruction was not given gratis; the young men were required to pay as well as to study, and the whole scheme seemed exceedingly well thought out. On these grounds the Committee felt that it had no other course, in the best interests of pharmaceutical education, than to recommend the grant being made. No doubt, it seemed somewhat large, but the district was large, and taking all things into account, he did not think they could do better than agree to it, it being understood, however, that no pledge was given as to repeating it next year.

Mr. Hampson asked if a grant for such a purpose was consistent with the regulations.

Mr. Brown said the application was made under the general provision "for the general purposes of advancing education where satisfactory evidence is given that the Association from which the application proceeds is really promoting that object, and needs assistance." He desired to express his obligation to Mr. Schacht for to a great extent relieving him from a distasteful duty; but the position in Manchester was this: they had already established educational arrangements, established a fair library, and a collection of materia medica specimens. On previous occasions when grants had been asked for by other associations, it had generally been at the commencement of the effort; but in Manchester they had carefully avoided making any such application until they had been established for some years, and had made some progress. He wished they had made better progress, and possibly they would have done so had they received a larger amount of aid, but still he thought they had shown a fair result for the amount at their disposal. He had certainly, in first bringing forward this matter, stated that this would have to be an annual grant, but this statement he begged leave to withdraw. He hoped local efforts would be so stimulated by the liberality which he trusted would be shown by the Council, that in future they would do more than they had done, and eventually succeed in establishing in Manchester a really worthy representative of the Pharmaceutical Society. They already had 80 members and 77 associates, but the expenses had absolutely run away with all the subscriptions. They were fortunate in obtaining the services of a very able teacher, who had hitherto relied on the fees received from the students, but it was felt that this remuneration was miserably inadequate to his services, and it had been resolved to supplement it by a fixed payment. Rent, however, and other expenses being very heavy in Manchester, they had no funds at their disposal out of which to pay the teacher, and under these circumstances they had determined to apply to the Society for assistance. The sum asked for, though large, was asked on a definite principle, viz., to meet the amount which they had guaranteed to pay to the teacher in addition to the fees he received from the pupils. This principle might not be applicable to every case, but it was a definite and comprehensible one; he did not think pharmaceutical students in the provinces any more than in London should be put off with any teaching short of the best, and for that kind of teaching they must be prepared to pay liberally. He did not like to promise anything beforehand, but he believed those associated with him in Manchester would agree in the hope that this was only the beginning of somewhat greater things, and that they might eventually establish in that large centre a school of pharmacy on a permanent foundation, and perhaps substantially endowed by local voluntary munificence.

Mr. Stoddart said Mr. Brown had removed the only difficulty he felt on the subject, because he did not think they could pledge themselves to an annual grant.

Mr. Brown stated in reply to Mr. Savage that they had 26 pupils, 80 members, and 77 associates; the members paid 10*s*. per annum, and the associates 2*s*. 6*d*. A good reading-room was provided, which was open every evening in the week, and there were also a library and a materia medica museum. The association was designed to benefit apprentices and assistants, and therefore the subscription was fixed at a merely nominal amount. There were classes in botany, chemistry, and pharmacy, and a special teacher of botany, Mr. Grindon, was engaged, who was paid by Mr. Siebold out of the 50*l*. fee which the Association guaranteed him. The fee for the whole of the classes was three guineas. He did not think good teaching should be offered at too low a rate, nor did his experience lead him to think that young men would object to pay fairly for first rate instruction. He expected that in future sessions there would be a large increase in the number of students attending the classes.

Mr. Savage thought the information was very satisfactory, and had pleasure in supporting the resolution.

Mr. Sandford said he should have much pleasure also in voting for the grant of £50, and also in considering the twenty other cases which the Vice-President had referred to, when they were brought forward. It was the very thing which he had long wished to see, for he had been disappointed that Mr. Schacht's proposition that grants should be made to provincial associations had not been taken such advantage of as might have been expected. He hardly agreed, however, with the principle on which Mr. Brown put forward his claim, namely, for £50 to pay the expenses of the lecturer, and would rather give it to the Manchester School without saying to what particular purpose it should be applied. If a society was doing all it could for education, it was entitled to assistance, whether for lecturing or other purposes. He did not think they should too narrowly interpret the regulations which had been laid down, but should assist any local Association where the work was well done.

Mr. Hampson said he did not like to give a silent vote on this matter. He came from Manchester, and had the deepest sympathy with what was being done in that district in education and other matters, but this was a very great step. He could not oppose it, because they were spending money on education in London, and therefore Manchester had an equal claim upon them. He had hoped, however, that these applications for aid would have died out, and that in the course of time students would have been ready to pay the market value for the knowledge they wished to obtain. This sort of thing enabled students to get education at a cheapened rate, and, on that ground, he objected to the formidable precedent now laid down. Still, as he said, he could not oppose the grant so long as they continued to cheapen education at Bloomsbury Square. There was one other point which he ought to mention, namely, that whilst aiding education in Manchester they were also aiding its local association, the purposes of which were not circumscribed by education. As they had been told, the Association was utilized, and properly so, for general purposes, and that he took to be a point to be considered in applications of this kind. However, whilst they continued to give help to local association, the Manchester school certainly deserved £50, or even £100, because the members had put their hands freely into their pockets to aid in the establishment of a high-class school of pharmacy.

Mr. Radley was very pleased to find that Manchester had made this application, and hoped it would be an encouragement to other places.

Mr. Atherton said a somewhat similar application was made from Sheffield three years ago, but was refused on the same grounds on which they were now going to make a grant to Manchester. He was very glad to see that the Council was getting more liberal, because this was the very ground on which he had always been anxious that money should be given—not that the rooms should be filled with diagrams and apparatus, to which the grants had been formerly confined, but that the money might be devoted to any purpose which advanced education.

Mr. Baynes thought the remarks of Mr. Sandford would produce a feeling of general satisfaction wherever local effects were being made for the advancement of pharmaceutical education. In his own district, they had felt it was almost useless to apply to the Council, because that body required such a strong case to be made out, and the assistance granted was so limited. He believed one result of making substantial grants to any society would be that they would take care to have value received, and that local societies would feel impelled to produce the best possible results, not only for the sake of the money they desired to obtain, but as a matter of pride, for they could not take the money without showing a fair balance-sheet in return.

Mr Frazer said he had taken very much interest in this question from the time he entered the society, and begged, therefore, to say only a few words, though he had been already anticipated by previous speakers. He hoped the idea which had been thrown out, that this application was only the first of many, would be realized, and believed that the reason applications were so few was, because the sums granted were so small. It was not worth the while of towns, such as Manchester or Glasgow, to make applications for small sums; in fact, he had himself prevented the people in Glasgow applying when it was only usual to grant about £10, but he should certainly not discourage them in future. He did not think there was any danger of expending too much money in this way, because each case would be dealt with on its own circumstances, and if they found that thirty or forty towns applied, and more money was required than they had to spare, the amounts must be proportionately diminished.

The Vice-President said he did not think any apology was due from him for having raised this question, and after the very important discussion which it had elicited, he felt very much pleased that he had done so. He had no desire to oppose provincial education in any direction, particularly in Manchester, and should be very happy to support the resolution.

Mr. Brown desired to say, in reply to a remark of Mr. Sandford, that, as Mr. Hampson had shown, there were reasons why any sum granted should not be given for general objects. Every provincial association must have some objects beyond the mere provision of educational arrangements, and its rooms would naturally be utilized in case of any political action being taken in connection with the Society or the general body of the trade. Such action might or might not be opposed to the feeling of the Council for the time being, and therefore he should not like to see the Society make grants for the general purposes of the local associations. As he had said at the outset, if this liberal grant were made, it would certainly involve a serious responsibility on the part of the administrators of the funds of the Manchester Association; but that he was prepared to undertake, and he hoped the £50 now granted might be seed thrown into good ground, and spring forth and bear fruit satisfactory to all. He might perhaps be accused of some inconsistency, inasmuch as on former occasions he had opposed the giving of small grants to local associations, but he was still opposed to these small grants, because they were of no use. He did not think any association which was so small that a £10 note could be of very great importance to it, had much to anticipate from its future work. It would be much better for such a society to wait until something had been accomplished, and then come with a definite object in view, and ask the Council to help it to something which it could not obtain by its own efforts. That brought him to the principle on which he asked for the grant, which was a definite one, and one which might be applied to provincial associations. The great vice of many such associations had been that they simply prepared young men to pass the examinations, but that was opposed altogether to the theory and practice of the professors of the Society, and was a vicious principle. What was wanted was a system of teaching extended over a considerable period, and to provide proper teachers for such a purpose proportionate payment must be made. Therefore, having exhausted local effort, he thought application might reasonably be made to the Society for assistance. In order to avoid rising again, he would venture to anticipate the favourable vote of the Council, and thank them for their liberality.

The President, before putting the motion, said he most heartily concurred in the grant, and in the observations which had been made by Mr. Sandford that they had hitherto been rather too stringent in their regulations.

Mr. Sandford wished to explain that he did not intend in any way to aid local societies for any political purposes, but he presumed that any case which came before the Committee would be examined on its merits, and if the Association was doing good educational work, the Council was bound in principle, if it had the means, to aid such Association.

The resolution was then carried unanimously.

Appointment of Examiners.

The following Pharmaceutical Chemists were appointed Examiners of the Society for the ensuing year, subject to the approval of the Privy Council:—

England and Wales.

Allchin, Alfred	London.
Barnes, James Benjamin	London.
Benger, F. Baden	Manchester.
Carteighe, Michael	London.
Corder, Octavius	Norwich.
Gale, Samuel	London.
Haselden, Adolphus F.	London.
Linford, John Samuel	London.
Martindale, William	London.
Moss, John	London.
Schweitzer, Julius	London.
Southall, William	Birmingham.
Taylor, George Spratt	London.
Umney, Charles	London.

Scotland.

Ainslie, William	Edinburgh.
Buchanan, James	Edinburgh.
Gilmour, William	Edinburgh.
Kemp, David	Portobello.
Kinninmont, Alexander	Glasgow.
Noble, Alexander	Edinburgh.
Tait, William	Edinburgh.
Young, James Robert	Edinburgh.

Benevolent Fund.

The Benevolent Fund Committee, in its Report, recommended that the following grants be made:—

£10 to the widow of a chemist and druggist, aged 53, who had received a similar grant in January last.

£15 to a former chemist and druggist in Essex, aged 75, who received £10 in March last.

£15 to a chemist at Liverpool, aged 58, completely incapacitated by paralysis. Applicant had previously received £10.

The consideration of another application from a widow with several children, was deferred for further information and inquiries as to the possibility of getting one of the children into an orphan asylum.

The Committee also recommended for adoption some amendments in the regulations of the Fund.

Some discussion arose as to a clause which proposed to give a vote for every subscriber of 2*s.* 6*d.* per annum, and ultimately, on a division, it was struck out, and the scale of votes ordered to remain as at present, viz., one vote for 5*s.*; two for half-a-guinea; four for a guinea, and so on.

Clause 4 was altered on the suggestion of Mr. Brown, it having originally provided that each pension should be of the value of £30. He pointed out that in some cases a less amount might be desirable, as, for instance, in the case of continuing the pension to the survivor of an aged couple.

Some discussion arose as to how the amount of the pensions should be fixed, and various difficulties were suggested.

Mr. Brown said he did not at all contemplate that the Council would grant pensions of less than £30; probably it would continue doing as it had been, but he did not wish its hands to be tied. He also suggested the addition of the words, "and any other particulars the Council may require," to clauses 6, 7, and 31.

The result of the discussion was to leave the Regulations in the following form:—

"1. The objects of this fund are:—

"To provide pensions for distressed persons who are or who may have been Members or Associates of the Society; for Pharmaceutical Chemists; for Chemists and Druggists; or for the widows of such persons.

"To afford occasional grants of money to distressed persons who are or who may have been Members or Associates; or Pharmaceutical Chemists; or Chemists and Druggists; or their widows or orphan children.

"2. At the first Meeting of the Council after the Annual General Meeting in every year, they will determine as to the expediency (financially) of electing pensioners in the month of October following.

"3. If the Council deem it discreet to elect pensioners, their decision will be made known by advertisement in the *Pharmaceutical Journal and Transactions*, and such other papers as the Council may direct, stating the number of annuitants to be elected.

"4. No pension shall exceed £30 yearly.

"5. Candidates for election must be at least fifty years of age.

"6. Petitioners for relief from this fund shall produce a certificate of moral character, and such evidence of their age as shall be satisfactory to the Council of the Society; shall state the time and place or places in which they have been engaged in business, whether on their own account or otherwise; how their misfortunes originated and when; their present means of subsistence, and from what source it arises; and the number of persons (if any) dependent upon them for support; and any other particulars the Council may require.

"7. Widows shall produce evidence of their age, the certificate of marriage, and the certificate of the burial of the husband, or such evidence as shall satisfy the Council on these points; the period during which the husband was in business, and where; the cause of misfortune; the present means of subsistence, and from what source it arises; the number of children (if any) dependent on them for support; and any other particulars the Council may require.

"8. In all petitions for assistance from this fund except those specified in clauses 9 and 31, the truth of the statements shall be certified by at least four members of the Society, or donors to the fund of *five guineas*, or persons who have subscribed not less than *half-a-guinea* per year for the three preceding years, and who are personally acquainted with the facts of the case.

"9. Widows or orphans applying for relief, and unable to obtain the required evidence under Rule 8, the Council will receive and consider in lieu of such evidence the testimony of four respectable householders, to whom the circumstances of the applicant may be known—provided that two of the persons so certifying are subscribers or donors to the fund.

"10. The Council, after due investigation, if satisfied that the case is an eligible one, will decide on the amount and character of the relief to be afforded.

"11. When the Council shall decide that any case is fitting for Annual Pension, the case shall be recorded in a book to be kept for that purpose, and immediately after the decision as to the expediency of electing pensioners (but not previously), notice shall be given to the persons whose names are so recorded.

"12. Pensions will be terminated by the Council in case of misconduct on the part of the recipient, or if the improved circumstances of the pensioner at any time shall appear to the Council to disqualify him or her to receive the benefits of this fund. In the case of widows, the pension will cease when they marry again.

"13. If at any time it shall become evident that the election of any annuitant has been secured by fraud or by false representation, such election shall be forthwith declared void by the Council.

"14. In case of a candidate being unsuccessful at the first election, credit shall be given for the number of votes at that and the four next succeeding elections, but not beyond that time.

"15. At every election of annuitants, five scrutineers shall be elected from the voters present to conduct the election, who shall report to the chairman the number of votes polled for the respective candidates.

"16. The chair at such elections shall be taken by the President, Vice-President, or a member of the Council for the time being.

"17. The votes shall be taken by polling papers, which shall be sent to every member and associate, and to life and annual subscribers entitled to votes under clauses 19, 20, 21, 22, 23, and 24.

"18. The polling-papers of members, associates, and subscribers whose payments are in arrear shall be withheld until the subscriptions be paid.

"19. Persons contributing *five shillings* annually shall have *one vote* at each election of annuitants.

"20. Persons contributing *half-a-guinea annually* shall have *two votes* at each election of annuitants, and persons contributing *one guinea annually* shall have *four votes*, the right of voting at such elections being increased in the proportion of *two votes* for every *half guinea* subscription.

"21. Persons contributing *five guineas* at one time shall have *two votes for life* at each election of annuitants, and persons contributing *ten guineas* at one time shall have *four votes*, the right of voting at such elections being increased in the same proportion by the same rate of contribution.

"22. Firms or corporations contributing *five guineas* at one time shall have *two votes* at each election of annuitants for the period of *ten years* from the date of such contribution, and firms or corporations contributing *ten guineas* at one time shall have *four votes* at each election of annuitants for the same period, the right of voting at such elections being increased in the same proportion by the same rate of contribution.

"23. Persons or firms giving donations of *less* than *five guineas*, shall have *two votes* for every *half guinea* subcribed at the ensuing election of annuitants.

"24. One executor paying a legacy of *fifty pounds* shall have *five votes* for life at each election of annuitants, and if it exceed £100, every one of the executors shall have the same privilege.

"25. The polling-papers and tellers' lists shall not be open to the inspection of any person without permission from the Council.

"26. Should a scrutiny be demanded or any complaint made in reference to the result of poll, the same shall be submitted to the consideration of the Council at their first subsequent meeting, and their decision shall be final.

"27. Every Member of the Society and every Associate of the Society in business on his own account, not in the receipt of nor an applicant for relief out of the Benevolent Fund will be entitled to two votes, and every Associate not in business on his own account, nor in the receipt of, nor an applicant for the like relief, to one vote.

"28. Every person entitled to vote in more than one class of voters shall be entitled to the votes due to him from each of such sources.

"29. In the event of an equality of votes, the chairman shall have the casting vote.

"30. Should any polling paper not be properly filled up or signed, the same shall be rejected by the scrutineers on their casting up the votes.

"31. Applications on behalf of orphans shall state their age and afford satisfactory evidence of the marriage and burial of the parents, and whether any means of subsistence have been left them; if so, its amount and the source from whence it arises, accompanied by a certificate signed as required by clauses 8 or 9; and any other particulars the Council may require.

"32. In the case of an orphan left under circumstances of urgent distress, the Council may, if they think fit, provide a home by purchase in one of the public asylums for orphans."

The report and recommendations were then unanimously adopted, and the purchase of £400 Consols to the Benevolent Fund account was ordered.

The SECRETARY announced that the subscriptions to the Benevolent Fund during the last year had already exceeded those of the former year by more than £150, and that in no case had a subscriber of 10*s.* 6*d.* reduced his subscription to 5*s.*, as some gentlemen had anticipated would be the case on lowering the amount of subscription necessary to confer a vote. He regretted, therefore, that the proposal to still further lower it had been overruled.

The VICE-PRESIDENT said the more liberal policy adopted during the past year had evidently produced a good effect. They had found an abundant return for casting their bread upon the waters, and he hoped the same course would be pursued.

A Common Room for Students.

The President read a petition which had been sent in, signed by 53 students attending the classes in the Society's School of Pharmacy, asking that they might be allowed the use of a room in the building for the purpose of conversation and discussion on matters connected with their studies.

Mr. Brown said the Council might refer this matter to the House Committee, but he was quite sure they would be desirous of granting the application, and he would therefore move that the petition be granted, so far as the arrangements of the house permit, and that it be referred to the House Committee to carry it out.

Mr. Schacht seconded the motion, and expressed his pleasure at the tone of the petition, and the earnestness on the part of the students which it evinced. They must all sympathize with them in their endeavours to perfect the educational work of the Institution.

Mr. Hampson hoped the House Committee would do its utmost in the matter.

The President did not think there would be any difficulty in providing a room for a certain portion of the day, but whether it could be spared the whole day he could not say. The Committee would certainly do its best to arrange matters satisfactorily.

Mr. Sandford said there were several things to be considered in connection with this question. Whatever room was granted to the students must be open to all members and associates, but many students were not connected with the Society at all. This matter arose from what had been said on a former occasion with reference to conversations taking place in the museum, to the interruption of study; but he believed the kind of conversation referred to in the petition would be perfectly admissible in the museum, and that the curator had himself stated that he should be very unwilling to stop any conversation of the kind. They must really consider whether, by granting the use of a room as was now asked, they would not be tending to empty the library and museum where young men should be studying. He, therefore, deprecated the passing such a definite resolution as Mr. Brown had proposed.

Mr. Frazer said this matter grew out of the regulation sanctioned last month to prevent conversation in the museum. It had occurred to him, since the last meeting, that the officer of the Society ought to be able to prevent any abuse of the privilege of conversation, and that the museum might with this restriction be used as heretofore.

Mr. Greenish said the regulation with regard to the museum was a perfectly proper one, as he had previously explained. He hoped the petition would be granted.

Mr. Betty suggested that the matter should be referred generally to the House Committee.

The resolution was ultimately agreed to in the following form:—

"That the Council desires to accede to the petition of the students so far as the arrangements of the house will permit, and that it be referred to the House Committee to carry out the necessary arrangements."

Foreign Societies.

Mr. Greenish asked the Council to order a copy of the *Pharmaceutical Journal* to be sent regularly, expense free, to three societies on the continent, viz., those of St. Petersburg, Bohemia, and Sweden. From the Russian Society they would get a journal in return, and from the others they would receive laboratory reports, and he hoped original papers for the Journal and the evening meetings. Professor Dragendorff, of the Pharmaceutical Institute at Dorpat, would also be glad to receive the Journal, and would send in return the printed papers prepared by some of his more advanced pupils, which would be a valuable addition to the library. Mr. Greenish added that the Russian Pharmaceutical Society had paid the Council the compliment of electing its two delegates to the late Congress honorary members.

Mr. Sutton thought they ought to send copies of the Journal to all recognized foreign societies, such as those at Copenhagen and St. Petersburg.

A resolution for forwarding free copies, as suggested by Mr. Greenish, was unanimously agreed to.

Report of Examinations.

November, 1874.

England and Wales.

	Candidates. Examined.	Passed.	Failed.
Major	2	2	0
Minor	15	4	11
Total	17	6	11

Five Certificates Received in Lieu of the Preliminary.

1 Society of Apothecaries.
1 University of Cambridge.
1 " " London.
2 " " Oxford.

PHARMACEUTICAL MEETING.

Wednesday, December 2nd, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed, the following Donations to the Library and Museum were announced, and the thanks of the Society were awarded to the donors:—

To the Library:—'Companion to the British Pharmacopœia,' tenth edition, from Mr. Peter Squire (the author).

To the Museum:—Specimens of Boldo and Jaborandi, from Mr. Morson; a photograph of annual and biennial Henbane, from Mr. R. Usher; a specimen of Tabashir, from Dr. G. C. Wallich; fine Crystals of Arseniate of Soda, from Mr. Geo. Green; a specimen of Cinchona Bark, containing Paricine, from Mr. W. Southall; specimens of Liquid Kino, from *Pterocarpus Indicus*; Burmese Varnish, from *Melanorrhœa utilitissima*; crude turpentine from *Pinus Khasyana*, from Dr. Forbes Watson; and the following specimens from Mr. D. Hanbury:—Yellow pareira brava; root bark of *Calotropis procera*; root of *Calotropis gigantea*; root of *Toddalia lanceolata*; leaves of *Tylophora asthmatica*; white pareira brava; calumba root, sliced and dried in London; cinnamon chips; cascarilla wood; gum of *Feronia Elephantum*; cortex thymiamatis; barba-timao bark; Guayaquil sarsaparilla; English coriander seed; English, Dutch, and Mogador caraway seed; Soymida bark; *Cassia vera* bark; Margosa bark; seeds of *Brassica juncea*; ishpingo; thick cinnamon bark; fruits of *Diospyros embryopteris*; schœnanthus; oleo-resin of *Hardwickia pinnata*; wood of xylobalsamum; pale catechu from *Acacia catechu*; root of *Xanthorhiza apiifolia*; root of *Cissampelos pareira* from Ceylon.

Boldo.

Professor Bentley exhibited some specimens of a plant which he said was now exciting some attention, from yielding the new drug called Boldo. But for the severe weather, he should have had the plant itself to exhibit at the meeting. He did not propose to enter into the merits of the medicine, his object was simply to show some recent specimens of the plant yielding it. The plant was now coming into the market, or at least would come into the market soon, as a drug. The name of the plant was *Boldoa fragrans*, or, properly, in accordance with the practice of botanists to take the prior name, it should be called *Peumus Boldus*. However, that was a matter of very little importance in a practical point of view. To those who were anxious to see the plant growing, he should be happy to give an order to view it at the Botanic Gardens. The plant at the Gardens was probably the largest in this country, being about twelve feet in height. All the characters of the plant might be seen from the present specimens. There were also present some flowers which had been described in the *Pharmaceutical Journal* about a fortnight since. The plant belonged to a small order called by botanists *Monimiaceæ*, allied to the nutmeg order to some extent, and also to the laurels. He should like to remark that the flowers were not, as described in the Journal, racemose, but what botanists called cymose, which was an important botanical distinction. One great peculiarity of the plant was the aromatic odour of its leaves. These leaves and young branches were reputed to possess tonic properties, and to form a valuable remedy in liver complaints, and certainly, from the testimony which had been given to their value, boldo was a substance, at all events, well worth trying. Whenever any substance came freshly to us, there was a possibility of its being spoken of too extravagantly, and it was the duty of persons in this country and on the Continent to test its properties. He could not say that he was himself satisfied at present that the efficacy of boldo as a medicine was in any degree established. There was a very valuable thesis published in Paris, and it would be found in the Journal; and he hoped that attention having been called to this drug, a supply of it would be obtained, and that it would be extensively tried in the hospitals. It had been tried to some extent in Paris, but not sufficiently to enable one to pronounce positively as to its merits. It was used for other purposes besides diseases of the liver, but at present we had no very detailed account of its physiological action, although it was evidently somewhat powerful, because if taken in certain doses it acted as a powerful emetic. It was, therefore, doubtless a substance which possessed some activity. The leaves contained a large quantity of volatile oil; their odour, when rubbed, was something like a tolerably common English plant, a small shrub, commonly called sweet gale, the *Myrica Gale*.

The President thought that the smell was something like that of verbena. He said that they were very much obliged to Professor Bentley, as they were always to any gentleman who brought new substances before them, particularly such as were likely to be tried in hospital or general practice.

Amorphous Phosphorus.

Mr. Greenish said he wished to make a remark arising out of the minutes of the last meeting. He said then that a medical man who had been in the habit of prescribing amorphous phosphorus had given up that substance for pure phosphorus. In a letter to the *Pharmaceutical Journal*, he had been asked by Mr. Postans for information as to the reason why amorphous phosphorus had been so given up. He had made inquiry, and found that the reason was the gritty character of that substance when administered mixed with syrup. He would also take that opportunity of remarking that notwithstanding all that Professor Redwood had said, he must adhere to his statement that they had no elegant form yet for the administration of phosphorus.

The Chairman said that, as Dr. Redwood was not present, they would, of course, abstain from discussing that question.

An Additional Test for Glycerine.

The Chairman said the first paper was a contribution from Professor Godeffroy, Professor of Practical Chemistry in the Vienna School of Pharmacy. This paper had been supplied to the society at the request of Mr. Greenish, who met the writer at St. Petersburg, and consequently this was one of the first fruits of their visit to the International Congress. He hoped that they would be supplied with many papers from similar sources.

The paper was read by Mr. Greenish, and is printed at p. 441. It gave rise to the following discussion:—

Mr. Greenish said that he had had three samples of glycerine tested by this means in his house by his son. The samples were Price's, Sarg's, and a German glycerine. Price's glycerine burnt, leaving simply a little sooty matter, but no other residue; Sarg's left a small quantity of residue and rather more charred matter. The sample of German glycerine, the maker of which he did not know, left a residue containing salts of lead and lime.

Mr. Robbins said he thought that this was a very good test for glycerine, but it was not entirely new. If he remembered rightly, the same test was published in the *Pharmaceutical Journal* some years ago. He happened to know a gentleman in the city, who bought a large quantity of glycerine at one of the exhibitions, when it was very dear, as only Price's glycerine was sold in the English market. The glycerine so bought was foreign, and was exhibited at the exhibition as something quite equal in every respect to Price's, and it was sold at a very much lower cost. The city firm sold it to its customers under the belief that it was selling pure glycerine. Some of it was examined, he believed, by Dr. Draper. There was then no known test for glycerine, but the examiner happened to try several methods, and this among the number. He found that the foreign glycerine was charred immediately, and that it consisted largely of grape sugar. He stated that pure glycerine would burn, and that it could be all distilled away without leaving any residue whatever.

Professor Attfield said that the paper which had just been read was partly new, and he thought that it was new to the extent to which it professed to be new. Respecting papers of this kind, there was no doubt that these international courtesies were very pleasant. This was not the first time that the presentation of a paper by a foreigner had taken place in England, and papers and notes by English pharmacists had occasionally been presented to scientific societies on the Continent. It was extremely desirable that such courtesies should be kept up. They promoted good feeling between the members of a common calling in different countries. With regard to the test itself, there could be no doubt that it had been known for a long time that glycerine was combustible, but it had not been generally recognized that glycerine, when heated, gave off a combustible gas, though the discoverer of glycerine himself alluded to the fact. At the same time, he thought it had not been generally understood that glycerine would so decompose without any unpleasant odour, and without leaving any residue whatever. The detection of sugar in that way had been, no doubt, suggested before. It seemed to him that Professor Godeffroy, from his remarks, offered this method as a sort of rough and ready test to be applied by any man who was not a chemist, in order to ascertain whether his glycerine was contaminated to any great extent. It would be pretty obvious to chemists that glycerine containing any large quantity of water, or any substance which would be likely, when heated, to yield water, could not ignite until that volatile substance had been expelled. But still, in offering a rough and ready mode of testing glycerine, it was desirable to call attention to that fact. Then, again, it would suggest itself to any chemist that glycerine, being a combustible body, any non-volatile residue which it contained would remain behind when the glycerine was burnt; but still it was desirable to point out that fact in offering a rough and ready test to persons who did not know much about chemistry. Again, with regard to substances which were not volatile, but which were combustible, Professor Godeffroy drew attention to the fact that such substances, if present in glycerine, would probably yield a residue of carbon when the glycerine was burnt, as in the case of sugar, or any other such substance. It was also important to draw attention to the fact that pure glycerine, when burnt, did not yield a residue, because in all works of reference on chemistry it would be found stated that glycerine yielded a residue. Chevreul, and Frémy, Gmelin, and the earlier workers with glycerine, all stated that when it was heated it yielded a combustible gas, and after ignition a residue of charcoal. If any one would try the experiment on the remarkably pure glyce rine which was to be met with now, putting about an ounce of it into a capsule and letting it burn away, he would find that practically there was no residue. Four or five hundred grains would scarcely yield a tenth of a grain of carbonaceous residue. He presumed that the glycerine which was experimented with in early days was scarcely pure, and hence the statement that it yielded a residue of carbon. Then the fact to which Professor Godeffroy called attention, as to the combustibility of cold glycerine by the aid of a wick, he (Dr. Attfield) did not think had been noticed before. As remarked by Professor Godeffroy, even glycerine containing water would burn. The speaker had placed in a vessel on the table some glycerine containing 10 per cent. of water, and it would be seen that it would burn by the aid of a wick. There was also some perfectly pure glycerine, which was very viscid, and hence it did not burn very well, but they would see that it would burn; and, of course, as they might expect, when it got slightly warm, and had become somewhat thin, it would burn very well. In a third capsule was some glycerine, which was warmed and ignited by Professor Attfield. It burnt away slowly with a slightly luminous flame, leaving a mere trace of carbonaceous residue.

Mr. Barnes said that there was an account contained last week in the *Daily News*, in the last article on the exhibition, in which it was stated that glycerine was burnt for giving light.

Mr. Moss said it would scarcely do to test all samples of glycerine by ignition in a platinum dish, for that some of the cheaper kinds were contaminated with lead salts, and at the temperature attained by the flame from an open Bunsen burner playing against the dish, these would be reduced by the carbonaceous residue and an alloy of lead and platinum be formed, to the serious detriment of the dish. If the Bunsen burner were used with the rose, he thought it would be found that even the best samples of glycerine would give a much greater proportion of carbonaceous residue than one-tenth of a grain from half an ounce. Professor Godeffroy said that pure glycerine (s.g. 1·26) will boil at 150° C. It seemed to him (Mr. Moss) that an error had crept in here somehow. A few bubbles escape at that temperature, but certainly the boiling (if boiling it were) at once ceased, and the temperature rapidly rose to 230° to 240° C. when ebullition fairly sets in. In an experiment made an hour previously, the lowest temperature at which the escaping vapour could be ignited was between 185° and 190°, tried with the temperature falling as well as with it rising.

The Preservative Effect of Chloroform upon Vegetable Infusions, etc.

A paper on this subject, by Mr. J. B. Barnes, F.C.S., was read. It is printed at p. 441, and gave rise to the following discussion:—

Mr. Gerrard said that he had that morning received a communication from Mr. F. J. Barrett, the pharmacist of the Wolverhampton General Hospital, which he would read. It was somewhat confirmatory of Mr. Barnes's remarks. This communication is printed at p. 442.

Mr. Umney said that he feared there was one serious objection to the use of chloroform in the dilute infusions in the proportion given by Mr. Barnes. In the ordinary dose in which infusions were taken, namely, from one to two ounces, such a proportion of chloroform would be almost equal (in chloroform) to fifteen or twenty minims of spirit of chloroform of the British Pharmacopœia, which would be an ordinary dose. It seemed to him that this was the chief objection to this method of preservation. Such a quantity of chloroform could not be used without materially altering the character of the infusions.

Mr. Gerrard said that Mr. Barrett had found that the sixth of a minim was sufficient to preserve one ounce of infusion for a period of several months.

Mr. Wilson said that the objection of Mr. Umney might be obviated to some extent in the case of some infusions by heating the infusion to the temperature of boiling water before using it.

Mr. Haselden said that he was very pleased to find that Mr. Barnes had once more brought forward the subject of infusions. Some years ago the question of how they might preserve fresh infusions, and yet not interfere with the processes of the Pharmacopœia, was constantly the subject of their attention. He confessed that he saw no difficulty whatever in the employment of chloroform in the proportion of five minims to eight ounces of infusion, except one, and that was a very serious objection. It was the question of whether the physician would like the pharmacist to give chloroform with every infusion he ordered, when he himself had no intention that such a thing should be administered. At the same time, when they considered that two prescriptions out of three contained spirit of chloroform, it would not be a matter of very great difficulty if the physicians were aware that fresh infusions were prepared with the assistance of chloroform. If such infusions were introduced into the Pharmacopœia, that would at once remove the difficulty. If the medical man did not wish chloroform to be contained in the infusion, it would be the simplest thing in the world to order a fresh infusion to be made, and to intimate to the patient that the prescription would require time to be made up. About seven or eight years ago infusions were very seldom prescribed. Medical men seemed to forget that there were such things as fresh infusions and concentrated infusions. That was about the time when the first British Pharmacopœia was brought out; but he was glad to see that about two or three years ago medical men had returned to the employment of infusions, and dispensers now very frequently found in the prescriptions infusion of calumba, gentian, quassia, and various other infusions. At the time that so much talk took place about preserving fresh infusions, the addition of spirit was suggested; the addition of tincture, and the boiling of infusions, and tying them over, as in the making of preserves, were also suggested. He believed that all those plans had been carried out to a certain extent, but they were never found to be very efficacious. Physicians would not mind their patients waiting a little for the infusion to be made, if it was so understood. They were constantly prescribing infusion of orange peel. He supposed they meant simple infusion of orange peel, and not the old compound infusion. The infusion of orange peel took a very short time to prepare, but would keep good only twenty-four hours. The time for its preparation was too short unless it were made from fresh orange peel; but seeing that the infusion was often prescribed at a time when fresh orange peel could not be obtained, and the infusion had to be made from dried peel, the time given by the Pharmacopœia was scarcely sufficient to get the full flavour of the orange peel. and therefore a longer time would be desirable. That ought to be borne in mind by the Pharmacopœia Committee. But to come back to the subject, he did not see any objection to the use of chloroform to preserve infusions, provided that the medical profession were made aware of the fact, and would agree to the practice.

The President said that what Mr. Haselden had said was important. They must get the sanction of the medical profession before the use of chloroform in infusions could be adopted; but he preferred the fresh infusions as at present prepared.

Mr. Moss said, that with regard to Mr. Umney's objection to the use of chloroform, it must be remembered that a twenty minim dose of Spiritus chloroformi contains nineteen minims of rectified spirit, which would certainly not be without effect when that remedy was administered. The spirit would not be in infusions preserved as suggested by Mr. Barnes.

Mr. Greenish said that there was some difficulty with regard to fresh infusions, but he still held to the opinion that there was nothing like them. He had seen a great many very good concentrated infusions, but when he came to dilute them, he found that they did not equal the fresh infusions. He felt very much indebted to Mr. Barnes for bringing this subject before the meeting ; but upon putting those bottles to his nose, he (Mr. Greenish) found that there was such a strong smell of chloroform that it would be quite impossible to use such infusions in ordinary dispensing.

The CHAIRMAN quite agreed that there was nothing like a fresh infusion. With respect to chloroform, of course, nothing could be done without the sanction of the Medical Council. He did not know whether any one present had tried the use of glycerine as a preservative. He did not think that it would be so objectionable as chloroform, and perhaps it might sweeten the infusion a little, and make it somewhat pleasanter.

Mr. URWICK said that the consent of the Medical Council would have to be obtained to the use of glycerine.

The CHAIRMAN : I quite agree with you.

Mr. URWICK said he had heard many say that they found a difficulty in the use of infusions, but he had never done so. He had never used concentrated infusions, but he always kept a supply of the others, and managed very well. They were far superior to the concentrated, and he should like to see the latter altogether banished.

Professor ATTFIELD said, that as the pharmaceutical aspect of the matter seemed to be worked out, he should like to say a word or two on the action of the chloroform, irrespective of the value which it might have as a preservative of infusions. Mr. Barnes in his note said that in his opinion the chloroform preserved infusions by its action on the fermentable substances held in solution ; but the question was, what was that action ? They had been told many times that infusions could be kept if the air was prevented from getting to them, and therefore it seemed as if the alteration of the infusions was due to some process in which the air had some action, and it was presumable that the oxygen of the air would attack the infusion, and also that bodies floating in the air might find their home for growth in the infusion. So long ago as 1850, the action of chloroform as an antiseptic was noticed in a pamphlet by Aujendie of Constantinople. He (Professor Attfield) did not know that the writer mentioned infusions, for he did not think he was a pharmacist ; but he went pretty fully into the action of chloroform in preventing alteration in meat and similar substances. This writer, and more particularly M. Robin of Paris, considered that the action was simply the prevention of oxidation. M. Robin went so far as to assert that the influence of chloroform when inhaled as an anæsthetic was to prevent the oxidation of the blood by the air.

Mr. MARTINDALE suggested that it was most probable that chloroform acted like carbolic acid or other antiseptics in checking the growth of septic germs which might exist in infusions. He believed that Mr. Barrett once used carbolic acid for preserving infusions, but that substance, to the extent to which Mr. Barrett used it, was very dangerous in consequence of its poisonous action. It would be interesting to know the effect of the addition to infusions of salicylic acid, which appeared to resemble carbolic acid in its antiseptic property.

Mr. GREENISH said that Mr. Barnes alluded to one subject which he thought was extremely interesting, and that was the keeping of waters and solutions. Mr. Rimmington, who had paid some attention to that subject, was present. He (Mr. Greenish) and Mr. Rimmington often found fungoid growths in the solutions, as in solution of arsenic and solution of strychnine. In the latter case almost the whole of the strychnine would be taken up by the fungoid matter. It was possible that chloroform might be useful in preserving such solutions, but it was a very large subject.

Mr. RIMMINGTON said that he had no doubt at all that the changes which took place in all vegetable infusions arose from fungoid growths, and that the only action performed by chloroform or any other preserving agent was to prevent such growth. Of course the nature of the growth which took place would vary with the infusion and the circumstances in which it was placed, but from his own experience he felt confident that the growth of fungi in vegetable infusions was the cause of their decomposition, and that any means which would prevent the growth of such bodies would secure the preservation of the infusion.

Mr. BARNES said that he did not suggest that chloroform should be added to infusions. He merely recorded the fact that it had preservative properties. He should not suggest its use unless it were sanctioned.

THE PRESERVATION OF THE LIQUID EXTRACT OF LIQUORICE ROOT.

The remarks on this subject (printed on p. 442), by Mr. C. Umney, gave rise to the following discussion.

The PRESIDENT said that they were very much obliged to Mr. Umney, and he supposed that they might look forward to having, in the course of two or three months, a paper on the result of what Mr. Umney had now put aside.

Mr. MARTINDALE said that a sample of the preparation which he had made in May last, and kept in a cool place, had completely gelatinized. A sample kept in a warm place had changed as Mr. Umney had described.

Mr. UMNEY said that he had noticed, on a large as well as a small scale, the decomposition which he had described. He had used large quantities of liquorice root since April, and he had seen the fermentation going on in the fluid extract when stored in bottles containing three or four gallons, and in a cool place.

Mr. GREENISH asked what temperature Mr. Umney's sample had been exposed to.

Mr. UMNEY said that it had been made in the cold, then raised to 212°, so as thoroughly to coagulate the vegetable albumen, evaporated by a water-bath, at a temperature of about 170° or 180° Fahr., and, finally, filtered. This was the process given in the Pharmacopœia, which was thoroughly sound in principle, and only required, he believed, more spirit to make it perfect. Most of them knew that 11 per cent. of spirit would not preserve preparations of this class.

Mr. MARTINDALE said that he thought that the preparation was too strong.

The meeting then adjourned to the 3rd February, 1875.

PRELIMINARY EXAMINATION.

The undermentioned certificates, in lieu of this Examination, were received by the Board of Examiners at their meeting on the 9th of October :—

Certificates of the College of Preceptors.

Aplin, Isaac W. ....Yeovil.
Glanville, George ....London.
Norburn, Albert Edward.........London.

Certificate of the Royal College of Surgeons of England.

Dyer, Edward Henry ....Horncastle.

Certificate of the Society of Apothecaries.

Savory, Arthur Ledsam ....London.

Certificate of the University of Durham.

Hurworth, Andrew Maitland ...Boston.

Certificate of the University of Oxford.

Fry, Henry ....Leicester.

NORTH BRITISH BRANCH, EDINBURGH.

The first scientific meeting for the session 1874-5 was held in the Society's rooms, 119a, George Street, on Thursday evening, 26th November, at half-past eight o'clock ; Mr. Gilmour, President, in the chair. There was a very full attendance.

The President made the following remarks:—

"One of the first duties which it becomes me to discharge to-night at this the first meeting of another session is to thank you very cordially for the honour you have done me in placing me in the presidential chair. In doing this I cannot but feel how much better it would have been had you chosen one with an older head and greater experience than I can lay claim to, to fill this important and honourable position. It is one I have always looked up to, particularly when filled, as it has been of late years, by men whom we all honour (and who are worthy of all honour), as one of great responsibility, and nothing would have induced me to comply with the call you have thus given me, had I not felt assured that I would have both your sympathy and co-operation in every duty which I might be called upon to discharge. Especially, gentlemen, do I ask this of you to-night in the somewhat peculiar and difficult duty which now lies before me in formally opening another session's scientific meetings. In doing this there are one or two things which I think it becomes me, before commencing more immediately the business of the evening, to take notice of as a cause for congratulation in our present position and prospects. And one of the first of these which commends itself to us is that we meet to-night in our new rooms with no small degree of comfort and pleasure. It is not necessary that I should here narrate all the steps which were taken after finding the old premises small and otherwise unsuitable, to find others, or how, after long and anxious search, your Council happily fixed on those we now occupy. But it is certainly matter for congratulation that we have been fortunate enough to secure rooms at once suited for all the purposes for which they are required, and convenient for all who may find it necessary to frequent them. And with this enlargement of our space it is pleasant also to anticipate a probable demand upon all the extra room which we have thus available. For some time it has been apparent that the Council of the parent Society has been not only willing but even anxious to supply our every want, and place us in a position hitherto unattained and unattainable by us. This, together with events which have more recently taken place, cause me to look forward with confident expectation to a not distant day when we will have both a museum and library worthy at once the name and the Society to which they belong.

"It is with great pleasure (coming more immediately to our winter's work) that I call your attention to the arrangements which have been completed for the admission of pharmaceutical students to a winter's materia medica course of lectures, in addition to the usual classes. I do not at the present time wish to enter upon the question either of education or examination, but this I would say; that whilst education will ever commend itself to every right-minded student more for its own sake than as a mere help by which they are enabled to pass the examinations, still we cannot shut our eyes to the fact that such examinations do now lie before them in their path; nor can we avoid the further probable fact that they will bulk very largely in all their calculations and plans; and it is therefore, I think, fit and proper we should hold out every facility and inducement to them to take advantage of arrangements such as those which are thus made for them every session. In getting them to join such classes, we have the best guarantee that they are obtaining an education which will not only enable them to pass creditably their examinations, but an education which will prove useful to them in all their future career.

"I have also much pleasure in further calling your attention to the list of able lecturers which our indefatigable secretary has secured for our winter's scientific course. Interesting as many of the lectures have been in past sessions, I feel assured that this winter's will prove as interesting and successful (if not more so) than that of any previous year, and I need not say that I confidently anticipate your countenance and support to the different lecturers who have thus so kindly promised their services on these occasions. The names of the gentlemen who have kindly promised papers are—Dr. S. Macadam, Dr. M'Kendrick, Mr. Sadler, of the Royal Botanic Garden; Dr. Craig, and Dr. Moinet."

At the close of these remarks Mr. Gilmour delivered a most interesting lecture, of which the following is a short abstract:—

Theory and Experiments in the Development of Science.

It was my wish to bring before you something which, whilst it would enable us to spend a pleasant hour, would at the same time prove of some lasting benefit to us in the way of improving and adding to our knowledge; but only those who have been in such a position as that in which I am now placed can understand the difficulty of the task, turn in what direction we may. Accident, however, determined what thought did not, and so having my attention turned for another purpose to some aspects of modern theory, I thought I might utilize a few of my thoughts in another direction of the same subject, and present them to you to-night. I need not call your attention to the fact of how largely science bulks in the thoughts of men as well as in the literature of the present day, or how important are the issues which it threatens to involve in its speculations. Time was when science was the goal of theory, but in these days it seems to have become the starting point only, and we are caused often to wonder if it can explain any phenomena, or if its province has degenerated into explaining that they are inexplicable either as to their final or proximate causes, and this, too when nature is giving out her secrets with a prodigality unknown during the past six thousand years of her history, and when, in addition, experiment and research have more abounded than in any previous age. He must, I think, be but an indifferent observer of the times who does not see all this; and more than an indifferent observer who does not occasionally stop to inquire into the cause and the probable ultimate influence which it may exert not only, and not so much upon himself as an individual, as upon the community, or nation, or world at large, to which he belongs, and of which he forms a living, thinking, responsible unit. I do not intend taking up this aspect of the question at this time, interesting though it be. I have a firm faith in the great truth so beautifully expressed by the poet, that

> "I doubt not through the ages one increasing purpose runs,
> And the thoughts of men are widened with the process of the sun's."

Only it becomes us in this widening process not to attach undue importance to individual action, or opinion, or wisdom, in case we succeed like many in our day in elevating, for the time being, every theory into fact, and every individual bearing the name philosopher into a god, knowing good and evil,

It is my intention to-night to speak upon science with more immediate reference to the spheres of theory and experiment in its development, first, because I hope to induce some of the young men now before me to turn their attention to the whole subject, if not for the purpose of becoming men of science, at least of becoming men of true principles, discerning clearly and soundly betwixt the true and the false in the great war at present raging betwixt new science and old orthodoxy; and second, and principally, because I firmly believe this to be one of the first and most important duties which we should be able to perform, to wit, the weighing and estimating betwixt good, honest, sound theory—theory which has first been the outcome of proper observation and deduction, and then the object of careful and proper experiment—and that abortive thing, born of mere ingenuity, with which at present the whole world of thought is surcharged.

How is this assay, it may be asked, to be accomplished? Mainly, I reply, by a clear and intelligent idea of the principles from which theory originates and is developed. All theory, we may take it for granted, owes its formation to the desire of the human mind to inquire into and understand the mysteries, or phenomena, or by whatever name we may name the unknown of nature. In this process of inquiry there are but two ways in which we may proceed with investigation, viz., from observed phenomena backwards to proximate or first causes, or the antithesis, from first causes upwards to effects. But whether we proceed to make investigation by this analytical or synthetical process, we ought never to forget or overlook the fact, that the probabilities are, we may have, after all, begun with defective principles. "Lay the theoretic conception" (says one of the greatest theoretic speculators of the present day), "lay the theoretic conception at the root of matters, and determine by rigid deduction what are the results which must of necessity grow out of this root." But what, let us ask, is this root or where are we to find it? Not, certainly, on the one hand, in any phenomena, isolated and viewed from one stand-point alone where all are related, and all are less or more affected by each other; nor certainly, on the other hand, in any causes or even facts that in their nature are less than unchanging and unchangeable. Our very premises, as I have already said, may be variable, uncertain, defective.

And if this is the case of the start-point, how much more is it with this whole process of deduction, however rigid? The deduction lies away beyond the reach of the external, but its confirmation lies in it, and hence to the fallacy of reasoning we have to add all the uncertainty of experiment. Not that experiment in itself is uncertain. It is the grand touchstone to which all theory must be brought for proof and verification, but this very verification may be, after all, of mere negative importance, if not positively misleading, as attaching only *a value* to theory, and not the demonstration of its exclusive truth. With all these barriers, need we wonder if the development of science has been painful and laborious, or if theory has abounded over experimental knowledge? Nay! it is only when we call them all up before us, and correctly estimate them, that we are enabled rightly to understand and appreciate the progress which science has made and is now making.

Without unnecessarily obtruding these different points, which I have thus so briefly summarized, it is my wish to bring them before you to-night, as it were practically, in tracing the development, through theory and experiment, of a branch of physical science, leaving you to draw your own deductions and conclusions. For many reasons optics commends itself to us for this purpose, but principally because it is a science entirely of modern growth.

The lecturer then rapidly sketched some of the theories of the ancient philosophers regarding light, showing more immediately how barren their whole results were, and how little research had accomplished even down to the sixteenth and seventeenth centuries, when Galileo and Kepler succeeded in making several important discoveries, not only in optical instruments, but also regarding light itself. These discoveries, in the new revelation which they brought, as it were, to men's minds, as well as in their very incompleteness, set men to theorize and investigate, and so prepared the way for the advent of the great founder of the science, Newton, whose theories, and experiments, and discoveries, as well as mistakes, the lecturer then proceeded to narrate. From the discovery of the composition of light and the experiments in verification of it, the subject was minutely traced up to the discovery of achromatism by Dolland, and onwards to the substitution of the slit by Wollaston, instead of the round hole which philosophers had up to his time used, and in consequence, the foundation of that most important of all modern discoveries—viz., spectrum analysis, by the discovery that the colours of the spectrum were not continuous; occasion here being taken to show that no science could possibly be confined rigidly to one groove, but would branch out in every direction, shedding light all around.

After touching on the nature and theory of colours, the phenomena presented by thin films and grooved surfaces were next dwelt upon, and the corpuscular and undulatory theories brought to bear upon them for explanation. The interest of the audience from this point onwards as the rival theories were brought to the test of experiment, was most marked, and never flagged as the lecturer went on to demonstrate how the undulatory theory not only accounted for, but even anticipated phenomena in a way which the corpuscular theory could not, and thus obtained over it.

In concluding, reference was made to the length of the waves for the different colours, and the mode explained how they were calculated, and a diagram was shown, illustrative of the difference betwixt Newton's light particle and a wave of light, etc.

The lecture was illustrated throughout by means of some very beautiful and interesting experiments, thrown upon a large screen by means of the oxygen light, and Mr. Baildon at the close proposed a hearty and cordial vote of thanks to Mr. Gilmour for the very able manner in which he had treated his subject, referring especially to the successful and striking way in which he had conducted his experiments.

Mr. J. R. Young, in seconding the vote of thanks, expressed the pleasure and gratification with which he had listened to the paper, and hoped that ere long Mr. Gilmour would continue the subject, and give the Society another evening.

The Secretary drew the attention of the meeting to the following presentations which had been made to the Museum and Library, all of which were placed on the table for examination:—

Museum:—Forty-five specimens in jars illustrative of the vegetable department of the United States Pharmacopœia; twenty-seven mounted specimens of plants for the use of students; thirteen specimens of dried plants for portfolio; seven specimens of woods and roots, all presented by the Society in London; specimens of boldo leaves, from Professor Archer, Edinburgh; specimens of boldo leaves on the stalk, from Messrs. T. Morson and Son, London; pure Nepaul pepper from Western India, by Mr. H. Hyne, London.

Library:—Prior on the Popular Names of British Plants, from Mr. Daniel Hanbury, London; Smithsonian Annual Report for 1871-2, from the United States; eight numbers of the Pharmacist, from Chicago; fourteen numbers of the Proceedings of the Royal Society of London, from John Mackay; complete list of the awards by the Juries of the International Exhibition at Vienna, from J. Mackay; list of the Athenæum Museum of Vienna; fourteen numbers of the Journal of the Chemical Society in London, from J. Mackay.

Thanks were voted to the various donors.

The New Regulations of the Board of Examiners.

Mr. Mackay then proceeded to make some remarks on the recent alterations in the examinations. He explained that he did this by special request, as not a few misapprehensions appeared to be entertained as to the real operation of these changes, for, notwithstanding the explicit manner in which the new regulations had been laid down in the printed syllabus of the Society, there yet appeared to be a considerable difficulty in the minds of many, regarding them. Mr. Mackay begged to be distinctly understood that he had no official explanation to give, but simply to indicate his own individual opinion as to the manner in which the alterations would probably be carried out. Alluding to the Preliminary or the first examination, he reminded the meeting that at the close of the year, Selecta c̄ Præscriptis and the London Pharmacopœia would be omitted from the Latin examination, and a translation of a portion of the first book of Cæsar only required. In addition to the arithmetic, a knowledge of the metrical system of weights and measures would also be expected. He then referred to the Minor examination, and spoke of the slight alterations in the departments of prescription reading and pharmacy; but referring to the subject of chemistry, he stated, from numerous letters and verbal inquiries, he found that the nature of the practical examination about to be exercised in this department was not understood, and impressed many with the idea that the new requirements would be much more strict than the old ones. Now, the real changes were to this extent, that a practical knowledge in chemistry would be required to be shown by actual manipulation. When, therefore, better understood, the present fear of this portion of the examination must be at an end, because if bottles containing certain salts in solution, or otherwise, properly labelled, were placed in the hands of the candidate with a request that suitable reagents be employed to prove the presence of such substances, the difficulty to many would be rather lessened than increased, as compared with having various chemical reactions committed to memory. Of course, no books or memoranda will be allowed in this examination, and the various changes will require to be written down and shown by equations or diagrams. He then drew attention to the fact that on and after 1st January, 1875, every candidate must have attained the age of 21, before coming up for his examination, and in addition to this, and looking forward two years, evidence would be required that each candidate had been employed in practical dispensing for at least three years.

In speaking of the Major examination, Mr. Mackay intimated that the written examinations would now be done away with entirely, and that instead of eight departments, the new regulations only comprised four. Of these four, materia medica and botany remained unaltered, but there will now be considerable laboratory practical work in connection with chemistry and materia medica. Books and memoranda will, however, be allowed during the six hours in the laboratory. This work will include proving by experiment the percentage of alkali and acid in solutions given and not labelled; testing for the presence of metallic and alkaline salts, and proving in each case the base and combining acid. Also, it will be necessary to show an acquaintance with the various scale preparations, and prove their presence by testing when in solution; to be able to determine the purity or impurity of medicinal powders, and if of the latter, the kind and extent of such adulteration; and to show an acquaintance with the various alkaloids; and to know practically volumetric analysis. In the *vivâ voce* examinations, which will be supplementary to this practical one, and be continued the following day, the candidate will require to know the various chemical salts, crystals, and liquids, and give an explanation of some of the processes in chemistry and in the arts. He will also be required to show an acquaintance with the atomic theory, latent and specific heat, polarized light, electricity, and magnetism.

The foregoing, when taken along with the printed statement issued by the Society in connection with the new regulations, may give a general idea as to the preparation required for the Minor and Major examinations.

Mr. Mackay again reminded the meeting that the remarks he made in no way committed any of the examiners either in London or in Edinburgh, as each member of the Board had full power to examine on his own particular subject, in any way he thought best, in order to bring out the knowledge which the Society required each party to have before he gained his diploma as pharmaceutical chemist, or was put upon the register as a chemist and druggist.

The thanks of the meeting were voted to Mr. Mackay for his remarks, and carried with acclamation.

Parliamentary and Law Proceedings.

Prosecution under the Adulteration Act.—Adulteration of Pepper.

On Friday, November 27, at the Borough Court, Bradford, Inspector Booker summoned several persons for selling adulterated pepper. The town clerk (Mr. M'Gowen) conducted the prosecutions, and Mr. F. M. Rimmington, the borough analyst, was in attendance. In none of the cases were the articles used for the adulteration injurious to health, but the adulterations varied from 20 to 30 and from 40 to 75 per cent. The principal commodity used to mix with the pepper was peameal, which may be had at about 1*d.* per lb.

The first case was against Roger Walker Barker, grocer, Leeds-road. Inspector Booker proved the purchase of the pepper, and Mr. Rimmington stated that it was adulterated with 40 per cent. of peameal and ground rice. Mr. Hutchinson, who appeared for the defendant, said that his client had purchased the pepper from a highly respectable person, Mr. W. C. Swithenbank, the central Mills, Armley, near Leeds; that he paid a good price for it, and that it was guaranteed on the invoice to be pure. He submitted that the defendant ought not to be held liable for the adulteration; but the magistrates held that the defendant certainly was liable, and he could have had the pepper analysed before selling it on the payment of 2*s.* 6*d.* to the borough analyst. A fine of 10*s.* and 8*s.* costs was imposed.

The next case, in which the pepper had been obtained from the same wholesale firm, was against Joseph Addy, grocer, 189, Leeds-road. The case was proved by the Inspector and the borough analyst, and Mr. Hutchinson was told by the magistrates that he need not argue the matter again, as the case was on all-fours with the other, and the same fine and costs would have to be paid.

Margaret Staincliffe, 6, Vicar-lane, had to pay a similar penalty and costs for selling adulterated pepper, which had come from a London firm, and had been sold to her by a Bradford house. The solicitor urged that it was very hard on poor shopkeepers like the defendant. The town clerk remarked that they would have no difficulty in getting their money back from the wholesale dealer when the article was guaranteed. They could have it analysed, then bring an action against the wholesale dealer, claim substantial damages, and he had no doubt they would get a verdict.

Mr. Hutchinson said he had instructions from his client to proceed at law to vindicate his position, and to recover damages for the injury he had sustained.

In the case of Luke Barber, grocer, 141, Leeds-road, the pepper bought was proved by Mr. Rimmington to be fully three-fourths peameal. It had been obtained as pure from Messrs. H. Glover, Sons, and Co., Leeds-road, Bradford. Mr. Ralph Fawcett, a member of the firm, put in an invoice, and said that they had bought about a ton of pepper from Messrs. R. Robinson and Son, Valley Mills, Beeston, near Leeds, and it was "warranted genuine" on the invoice. The defendant was similarly fined to the others.

John Noble, grocer, 51, Bridge-street, bought his pepper from an eminent firm as pure, but had not got a guarantee to that effect. Mr. Rimmington said that this sample contained from 20 to 30 per cent of tapioca starch, and rice flour. Like penalties and costs were inflicted.

James Sharp and Co., 94, Godwin-street, had bought a quantity of pepper from Messrs. Topham Brothers, but it appeared that it was adulterated with from 20 to 30 per cent of peameal. As in the other cases, a fine of 10*s.* and 8*s.* costs was imposed, and the town clerk, in conclusion, told all the defendants who had a guarantee that they had their remedy elsewhere, but the inspector only knew the persons who sold adulterated articles.—*Leeds Mercury.*

Extensive Poisoning by Arsenic.

It is reported that upwards of fifty persons connected with the works of the West of England Fire-clay Company, near Calstock, in Cornwall, have been made ill by drinking water from a tank into which some arsenic had been thrown, it is supposed, maliciously. Three of the sufferers are said to be in a dangerous condition.

Alleged Attempt to Poison by Corrosive Sublimate.

On Tuesday, at the Worship Street Police Court, William Cherry was charged on remand with attempting to murder his wife by poison. The particulars of this case were reported last week. After some further evidence had been given, the magistrate decided upon committing the prisoner for trial.

Notes and Queries.

[419]. PHARMACY IN NEW ZEALAND.—I shall be much obliged to any reader who will give me any information, in this Journal, as to the state of pharmacy in New Zealand, and what is the average assistants, salaries ?—R. M.

[420]. PEARSON'S SOLUTION.—Can any reader inform me whether the solution known as Pearson's solution was introduced by Dr. Richard Pearson, of Birmingham, or Dr. George Pearson, of Doncaster? The time of its introduction was probably early in the present century.—H. Kerr.

Correspondence.

The Board of Examiners.

Sir,—The Council has an undoubted right to challenge the Board of Examiners if there are any weak members on it, but after the really Herculean efforts on the part of that Board in July and the preceding months, it does not appear very gracious to do so.

It cannot be too fully borne in mind the examiners must be taken from a class of thinkers and workers, with natures very different and often quite incompatible with those qualities which often place men on the Council; and with that learning, thought, and patient study which can alone command the respect and veneration of students, there is often an intense sensitiveness which a word used heedlessly in debate cannot fail to wound.

All I desire is to see on that Board men who can ably take the places of many who have left it, and the Society will not suffer.

Medical pupils revere most both as teachers and examiners men who have successfully, and with some mark, done what the students themselves aspire to—men who have put themselves on the world's judgment, and have won its approbation and support in their respective callings.

George Mee.

79, Grosvenor Road, Highbury New Park, London, N., Nov. 25, 1874.

Liverpool Chemists' Association.

Sir,—At Mr. Siebold's request, I hasten to correct a slight exaggeration of my remarks in introducing him to his audience at the last meeting of the Liverpool Chemists' Association, as reported in your issue of the 28th ult.

The words used were ". . . . a gentleman whose enthusiastic devotion to scientific pharmacy has raised him to the position Mr. Siebold now holds. As representative of our art at one of the principal scientific colleges in the world, and with our kindred association at Manchester," etc., etc.

On such an occasion, perhaps, a little license is allowed, and I would have preferred to let the matter rest, but Mr. Siebold's usual love of accuracy forbids our secretary to anticipate for him the honour referred to; and as this paragraph has caused Mr. Siebold (to whom we are much indebted for his very excellent lecture) some unpleasantness, which I sincerely regret, I must ask you kindly to insert this in your next issue.

Alfred H. Mason.

Liverpool, December 1, 1874.

[*** Mr. Siebold held an appointment, as lecturer on pharmacy at Owen's College, before the Manchester School of Pharmacy was separated from that institution.—Ed. Pharm. Journ.]

A. T.—See a paper entitled "A Cheap Disinfectant," read by Mr. E. C. C. Stanford before the British Pharmaceutical Conference in 1872 (Pharm. Journ. [3] vol. iii. p. 237), and another by Mr. Wanklyn on the "Action and Relative Value of Disinfectants" (vol. iv. p. 205).

A.—A formula for Syrup of Lasto-Phosphate of Iron and Lime was published in vol. iv. p. 610.

B.—According to the preface of the British Pharmacopœia the avoirdupois ounce would be implied though it is possible the Apothecaries' may be intended.

Lytta.—(1) Liquor Epispasticus, B. P. (2) The "Papier nitré" of the French Codex is prepared by steeping unsized paper in a cold saturated solution of potassium nitrate in water, and afterwards drying it.

"*A Student.*"—In the Minor examination a candidate is required to determine practically, by means of tests, the presence in solution of the chemicals in common use, and to explain the reactions which occur in each case.

S. Nockolds.—You will find a full description of croton chloral in the *Pharmaceutical Journal* for Oct. 31, p. 341.

J. Parker.—Yes, if required.

F. Booth.—Parrish's Treatise on Pharmacy, published by Baillière, Tindall, and Cox.

C. M. P.—The context would indicate the sense in which the words are to be construed.

"*Inquiro.*"—We are unable to answer your questions.

H. Mortimer.—See an article in the present series of the *Pharm. Journ.*, vol. i. p. 225.

A Country Pharmacist.—The Council would be unable to adopt such a course as that you recommend, without the sanction of Parliament.

R. H. R.—"Posological Tables," by Dr. W. Handell Griffiths. Published by Baillierè, Tindall, and Cox, King William Street, W.C.

P. B.—(1) It acts as a mechanical purifier. (2) No. (3) Analytical tests for distinguishing hydrates, carbonates, bicarbonates, etc., will be found in any good manual of chemistry.

"*One who takes an Interest in the Society,*" who writes to complain that he has been unable to obtain modern manuals of botany from the Library of the North British Branch, had better communicate personally with the Secretary in Edinburgh, who will most likely do what he can to oblige him.

"*Minor*" is referred to the rule respecting anonymous communications.

"*A Case for the Benevolent.*"—In the letter of our correspondent, Dr. Bathurst Woodman, published in last week's Journal, he has fallen into an error, which escaped our notice at the time. Mrs. Newby was not excluded from assistance by the rules of the Benevolent Fund, as Dr. Woodman states, because her husband was not a Pharmaceutical Chemist, but in reality because he was not a Registered Chemist and Druggist. We may take this opportunity of remarking that grants from the Benevolent Fund are not confined to Pharmaceutical Chemists, but are equally available for all registered Chemists and Druggists, their widows and orphans.

"*Pills.*"—We think it would be more digestible in the natural condition, if fresh and good.

Communications, Letters, etc., have been received from Mrs. A. Thompson, Mr. Durrant, Mr. Finch, Mr. Postans, Mr. Fairlie, Mr. Clarke, Mr. Robinson, Mr. Taylor, Mr. Mortimer, Mr. Booth, Mr. Parker, Mr. Holdsworth (Victoria), A., P. B., H. M. W., R. H. R., Bristoliensis, A Student, A Country Pharmacist.

NOTICE.—In consequence of the length of the official reports we are compelled to defer the publication of several communications.

THE USES OF AGAVE AMERICANA.

BY JOHN R. JACKSON, A.L.S.,

Curator of the Museums, Royal Gardens, Kew.

Some attention has lately been drawn to the common Agave (*Agave Americana*) on account of its supposed efficacy as an antiscorbutic. As noticed in this Journal last week, General Sheridan, whose name is as a household word in the United States, is said to have used the juice with great success amongst his men, who were suffering from scurvy in a small isolated post on the Texas border. The disagreeable smell of the juice, which has been compared to that of putrid meat, causes a person at first to turn from it in disgust, but after a while the odour is overcome, and a liking for it takes the place of the previous dislike. From the compulsory doses of this juice taken by Sheridan's small army, the effectual stay of scurvy is attributed. In Mexico the plant is very highly valued for its medicinal properties, the belief in which, amongst the Mexican peasants, has been handed down from a remote period of history. Thus, the gum found in the lower part of the stem is used as a cure for toothache, whilst the juice of the leaf is applied to bruises and contusions. This juice forms a large article of internal trade in Mexico. The plant is known as the "Maguey," or "tree of wonders," and even at the present time, in some parts of Mexico, it is considered one of the most important productions of the soil. The discovery of the juice of the plant as an intoxicating beverage is said by some to date back to the days of the early inhabitants of the Mexican continent. In an interesting report on the history, culture, and trade in the plant furnished to the Foreign Office some short time since, we read that "more modern tradition has fixed the epoch of its discovery as having been about the year 1045 to 1050, under the reign of the eighth King of the Taltec tribe, named Tepancaltzin, at whose court a relation of his, named Pepantzin, presented himself, and informed him that his daughter had discovered that a sweet and aromatic liquid sprung forth from the Metl plants in her garden. The King ordered her into his presence, and she brought him a 'Tecomatl,' or vase of the liquid she had discovered, which he tasted, and then ordered her to bring him more; and subsequently, becoming enamoured of the maiden, whose beauty was great, and whose name was 'Xochil,' or flower, he married her; of which union a child was born, to whom was given the name of Meconetzin, or 'Son of the Metl;' or, Maguey, in allusion to the circumstance which was the origin of his parents' first interview."

Leaving its very remote history, there seems "no doubt that the divers properties of the plant itself were known many years before the discovery of Mexico by the Spaniards, for not only is it mentioned as furnishing thorny scourges, as well as whips made of the fibres of the plants' leaves for the multitudes who annually met to celebrate a festival in honour of the god, Texcatlipuca, in the great Temple of Tenochtitlau (the modern Mexico), but the use of the juice became so general that many severe laws against the drunkenness resulting from it were issued by the ancient Mexican kings; mention being made of a widow who sold it promiscuously having been put to death by order of the king, Netzahualcoqatl; only women suckling infants, old people, and soldiers upon the march being allowed to drink it." Several varieties of the plant are cultivated in Mexico, each being known for the greater or lesser quantity of the juice it produces, its colour, whether yellow or greenish, its thickness, or sweet or bitter taste. These variations as to the properties or consistency of the juice depend a great deal upon the nature of the soil, and of the range of temperature; thus it is the least mucilaginous in a somewhat clayey soil, and is cultivated with the greatest success at an elevation of about 9,000 feet. Though the plant is cultivated very largely in many parts of Mexico, it is in the plains of Apam that the greatest Agave district is situated; more than 600 square leagues are here almost covered with the plant, either in its wild or cultivated state. The mode of propagation is by removing the young plants or suckers from the old ones, and after spreading them on the ground for two or three months to partially dry them, so that they may not rot, instead of starting into growth, they are planted in rows, and barley sown between them, which is considered rather to assist their growth. In a good soil the agave plant requires a period of from ten to twelve years before attaining maturity. "The plant upon attaining its full growth, which is easily discernible by its height and the prodigious extension of its leaves, brings forth a tall stem crowned with yellow flowers, and then a certain amount of pruning becomes necessary so as to form a kind of reservoir in the centre, and what is technically termed a "cara" or "face," around it, so as to cause the juice to flow towards the same spot, and to facilitate the extraction of it by removing some of the interior leaves and thorns."

To collect the juice, or "pulque," as it is called, as soon as the leaves begin to turn yellow a small concave aperture is scooped in the core of the plant, and an elongated tube-like gourd, the air in which is exhausted by suction, is thrust into the aperture; each labourer carries with him, strapped to his back, an impervious sheepskin bag, into which the gourd tube is emptied as soon as it is filled. From 50 to 60 plants are usually allotted to the care of one man, and from these he extracts, on an average, about 110 to 120 arrobas of juice, called honey-water, per week. After each plant has been exhausted of its juice—and often two collections are made in one day—the apertures or incisions are carefully covered up with leaves and stones to preserve them from the attacks of cattle, dogs, and a kind of jackal, common in the country. The pulque manufactories on the plantations, to which the juice is removed after collecting, consist of long, covered, and well-ventilated galleries, in which are rows of vats made of bullocks' hides stretched over a framework, and covered with lime; the juice is emptied into these vats, and allowed to stand for about thirty-six hours, when fermentation ensues, and its yellow transparent colour changes into a milky white. After fermentation the juice or pulque is ready for use, and is then sent off to the City of Mexico, Puebla, or the nearest market within a radius of 20 or 30 leagues; the pulque very commonly undergoing a considerable dilution of water by the way at the hands of the carriers who convey it in sheepskin bags upon mules or donkeys. The quantity of it which thus annually enters the City of Mexico alone may be estimated on an average to be about 2,000,000 arrobas, and that which enters Puebla to be about 500,000 arrobas, and the cost of transport alone has been calculated, taking the approximate average of 1 real as that of each arroba, to represent the sum of 312,000 dollars; not less than 20,000 mules and donkeys laden with the beverage entering the city every month by the gate leading to the Maguey districts. To the quantity paying duty must also be added a considerable quantity which is smuggled in, and including this it may be calculated that about 50,000,000 bottles are now annually introduced into the City of Mexico.

"From a chemical analysis of pulque it is found to contain, in different proportions, according to its quality, alcohol, mucilaginous fecula, sugar, water, and potash. It has been observed that the drunkenness produced by it under its different varieties is of a less violent description than that produced by another common beverage of the country, 'chinguirito' (brandy made from the sugar-cane), and that *delirium tremens* is rarely produced by the immoderate use of the former, though often by that of the latter. It is also affirmed that the pulque drinker is commonly long-lived, whilst the reverse is the case with regard to persons addicted to 'chinguirito,' and that the former beverage, notwithstanding its somewhat acid taste, is, probably on account of the fecula contained in it, peculiarly beneficial to women suckling their infants, and to those people whose constitutions require a wholesome stimulant."

Besides this pulque which, as we have seen, is the chief product of the *Agave* in Mexico, a strong spirit is prepared from the sap, known as mezcal, also a kind of brandy of 80 degrees of strength, a sweet, thick substance resembling honey, a concentrated gum used in medicine, brown sugar, loaf sugar, sugar candy, and vinegar of very excellent quality, so that the *Agave*, the value to us of which is mostly for its fibre, is, in fact, one of the most important economic plants of Mexico.

EXTRACT AND FLUID EXTRACT OF GUARANA, WITH GENERAL REMARKS ON THE MANUFACTURE OF MEDICINAL EXTRACTS.*

BY J. B. MOORE.

Paullinia has, within the last few years, attained considerable local popularity, and has been extensively prescribed in some parts of the United States.

Physicians, however, appear to be very unsettled, not only in regard to its physiological action and therapeutic application, but also in regard to the dose in which it should be administered. Upon inquiry among his medical friends who have used guarana in practice, the author received very conflicting reports of its therapeutic value. While some extolled it highly, others condemned it as worthless and almost inert. Unfortunately, physicians frequently make a great mistake in their experiments to test the effects of a remedy, and to ascertain its true physiological action, by too often prescribing the remedy under trial associated with other active medicinal agents, effects being often credited to the new remedy that are due to those with which it is associated. To judge, with any degree of accuracy, of the effect of a remedy, it should be prescribed alone or with comparatively inert substances.

The author had occasionally received prescriptions for it in powder, for the last two or three years, but it was not until recently that he had it prescribed in the form of fluid extract; and not having any of the latter on hand, and knowing of no published formula by which to make it, he concluded it would be well to devise a formula and process for its preparation. The expensiveness of guarana, however, made it rather an uninviting subject for experiment; but as he was fortunate in his first conception of its character, and the proper strength of menstruum required for its exhaustion, he encountered but little difficulty in framing what he considers to be a suitable formula, as follows:—

℞ Pulv. Paulliniæ . . . . . ℥xvi troy.
Alcohol. Fort.
Aquæ . . . . āā q. s.

Mix three measures of stronger alcohol with one of water, moisten the powder with the menstruum, and pack it in a glass funnel prepared for percolation, and gradually pour the menstruum upon it until one pint of tincture is obtained. Set this aside in a shallow vessel to evaporate spontaneously to twelve fluid ounces; continue the percolation with the same menstruum until two pints more of the tincture are obtained, or until the powder is exhausted. Evaporate this portion by means of a water-bath, at a temperature not exceeding 140°, to four fluid ounces. Mix this with the reserved tincture and filter through paper.

This formula is stated to yield a perfectly reliable preparation, which is transparent, of a deep reddish-brown colour (almost identical in appearance with the fluid extract of gentian), with a bitter, astringent, not unpleasant taste, leaving an after-taste on the palate strongly resembling that of coffee. The menstruum employed in the above process is found to thoroughly exhaust the drug of its virtues, and the proportion of spirit retained in the finished product holds in perfect solution all its soluble active matter. A sample of this fluid extract, made over three months remained still in excellent condition, showing no signs of change, and entirely free from deposit.

In an emergency a solid extract of guarana may be made by carefully concentrating the fluid extract, by means of a water-bath, to the proper consistence. But, as this medicine is likely to be often prescribed in the form of pills, a definite formula and process for making a solid extract would be preferable. The author therefore offers the following, which he says affords an excellent solid extract of the drug, unimpaired by process of preparation, if the directions given for its manufacture be observed:—

℞ Pulv. Paulliniæ . . . . . ℥xvi troy.
Glycerinæ . . . . f℥ss.
Alcohol. Fort.
Aquæ . . . . āā q. s.

Mix three measures of stronger alcohol with one of water, moisten the powder with the menstruum, pack it in a glass funnel prepared for percolation, and gradually pour the menstruum upon it until one pint of tincture is obtained. Set this aside in a shallow, open vessel in a warm place. Continue the percolation with the same menstruum until two pints more of tincture are obtained, or until the drug is exhausted. Evaporate this by means of a water-bath, at a temperature not exceeding 140°, to a syrupy consistence. To this add the reserved portion and the glycerine, and continue the evaporation at a temperature not exceeding 120°, until the whole is reduced to the proper consistence. During the concentration, in making this extract, the liquid should be stirred almost constantly, and especially is this necessary at the close of the process.

The author appends the following remarks on the manufacture of extracts:—

In the manufacture of all extracts, both solid and fluid, the important precaution of stirring during the evaporation should be observed, as it is by the neglect of this that the products in such cases are so often injured by heat. When it is observed, the concentration proceeds more rapidly and satisfactorily, and the medicinal virtues of the drug under treatment thus enjoy a comparative immunity from the injurious influences of heat.

In making fluid extracts, when reserved portions are to be concentrated to a given point, by either artificial or spontaneous evaporation, preparatory to receiving the product of the remainder of the percolate, it is very

* Abstract of a Paper in the *American Journal of Pharmacy*.

important to see that the concentration does not proceed too far. The evaporation should be closely watched, and the moment it has reached the desired point, the liquid should at once be transferred to a bottle and tightly corked, to await the product of the remainder of the process. The neglect of this apparently trifling point is often the cause of entire failure, or at least of great inconvenience, and not unfrequently leads to the production of imperfect and faulty preparations; as, owing to the uncertainty of the composition of the liquid after evaporation has once been permitted, its loss cannot be supplied with any degree of accuracy, especially when it is a liquid of a compound nature; such, for instance, as alcohol. Formulæ are in this way sometimes blamed for imperfections when it is the carelessness or inattention of the operator that is at fault.

Much care is also necessary in the concentration of the *last* portion of the percolate in making fluid extracts; where the liquid to be evaporated is a simple, as water, ether, chloroform, etc., the same care is not requisite to guard against excessive concentration, as the loss, in such cases, may be supplied by the addition of fresh portions of the respective liquids. Nor is it so important even when alcohol is the liquid under treatment, if, in the operation, *all* of the alcohol is supposed to be expelled, because then water may be used to make up the loss, but if the spirit is to be only partially driven off, then care is absolutely necessary, for reasons above stated.

If the attempt be made, under such circumstances, to supply the waste occasioned by excessive evaporation, it may be the means of causing précipitation or other untoward result, when this portion of the percolate is added to the reserved portion. It is the object of the suggestions offered in this paper to impress indelibly, if possible, upon the minds of all inexperienced pharmacists the importance of these little points that are so essential to success in all pharmaceutical manipulations, yet which are so often overlooked, both by writers and teachers.

When a hydro-alcoholic liquid is to be evaporated, and it is important that all the spirituous portion should be expelled, this will be only imperfectly accomplished if the liquid is not diligently stirred. The agitation throws fresh portions of the liquid constantly to the surface, and thus favours the liberation of the alcohol.

By the above process the author obtained from nine hundred and sixty grains of powdered guarana, three hundred and thirty grains of extract of a good pill consistence, which is about one-third, or thirty-three per cent. of its weight.

This yield was the result of a carefully-conducted experiment, in which no glycerin was used; although he does not think that the presence of the glycerin would influence the result much, as it simply takes the place of the water that would otherwise be retained in the extract to give it consistence. This small proportion of glycerin, he thinks, will be sufficient to preserve the extract in good pill consistence for an almost indefinite period. He has a sample of extract of gelsemium made in January, 1869, and another of extract of opium, made about eighteen months ago, to which was added about the same proportion of glycerin, and these extracts at the time of writing were in as good condition as when first made.

Mr. Moore is of opinion that pharmacists would find the addition of from five to ten per cent. of glycerin to all extracts prone to harden in keeping, would save them the annoyance so frequently experienced in dispensing from this cause. He has been in the habit, also, of incorporating a small portion of glycerin with blue mass just when it begins to stiffen and become inconvenient for forming into pills; he adds just enough to restore it to a good pill condition.

In the United States Dispensatory, page 1670, edition 1870, guarana is directed to be given in substance, in the dose of from one to two drachms, while of the extract only from eight to ten grains are directed to be given *during the day*, in pill form. Here there seems to be a great and unaccountable disparity of dose between the extract and the powder. Either the dose of the powder is unnecessarily large or that of the extract is much too small. The dose in which the powder is directed, the author thinks, is no doubt excessive, and that the proper dose of guarana, in substance, would be from fifteen to thirty grains. Taking this as a basis, the dose of the fluid extract would be from fifteen minims to a half fluidrachm, or from about twenty-three to forty-five drops, as a fluidrachm was found to contain about ninety drops, as dropped from the lip of an ordinary six-ounce prescription bottle; while the dose of the solid extract would be from five to ten grains, to be repeated every two, three or four hours, or three or four times a day, according to circumstances.

The fluid extract of guarana is most agreeably administered mixed with simple syrup or the syrup of orange, in the proportion of from fifteen to thirty drops to a dessert-spoonful of the vehicle.

In the treatment of various nervous affections, headaches, etc., Mr. Moore thinks it probable that bromide of potassium, valerianate of ammonium, hydrate of chloral, valerian, morphia, belladonna, hyoscyamus, and tincture of hops will be found to be its best adjuncts and most eligible associates in a prescription.

As syrup seems to be so pleasant a vehicle for guarana, a syrup of guarana would probably be a very desirable and useful preparation of the drug, and Mr. Moore is about commencing some experiments with the view of framing a suitable formula for such a preparation. The dose of guarana in substance is so large, and it requires so strongly alcoholic a menstruum for the solution of its active principle, that the proportion of spirit in a tincture would possibly be objectionable, and would be injurious, therapeutically, in the class of diseases in which guarana would be likely to be most generally employed.

ACTION OF BROMINE UPON SOME ALCOHOLS.*

BY M. HARDY.

The action of bromine upon alcohol has been long studied. In 1832, Loewig recognized that bromal is one of the products of the reaction. He prepared it by pouring gradually three or four parts of bromine into one part of absolute alcohol, kept cool with ice; after standing for a fortnight, he distilled off three-fourths of the liquid, and then added water to the residue, and thus obtained crystals of hydrate of bromal. Schoeffer caused bromine vapour to pass into a relatively small quantity of alcohol, and, as products of the reaction, obtained bromide of ethyl, hydrobromic acid with a little bromine, a small quantity of acetic ether, bromal, bromoform, tetrabromide of carbon, and a substance which was decomposed by water, giving bibromacetic acid.

Schoeffer's process, like that of Loewig, caused the formation of a quantity of secondary products, and did not manifest clearly the transformation which alcohol undergoes in the presence of bromine. This may be accomplished by dropping into a long-necked vessel containing absolute alcohol a suitable quantity of bromine in successive portions, so as to avoid too great elevation of temperature, sealing the vessel in a lamp flame, and heating it during several hours to 100° C. in a water-bath. When the reaction has terminated no gas is evolved upon the opening of the vessel, and the liquid, perfectly decolorized, forms two layers, which may easily be separated. The upper layer contains hydrobromic acid in solution in water; the lower contains bromide of ethyl and bromal, a portion of the latter being free and a part combined with a molecule of alcohol, forming a compound similar to the alcoholate of chloral described by M. Per-

---

* *Comptes Rendus*, vol. lxxix., p. 806.

sonne, and which the author proposes to call alcoholate of bromal.

$$3(C_2H_6O)+8Br=$$
$$\underbrace{C_2H_5Br}_{\text{Hydrobromic ether.}}+\underbrace{C_2HBr_3O,C_2H_6O}_{\text{Alcoholate of bromal.}}+4HBr+H_2O.$$

$$2(C_2H_6O)+8Br=\underbrace{C_2H_5Br}_{\text{Hydrobromic ether.}}+\underbrace{C_2HBr_3O}_{\text{Bromal.}}+4HBr+H_2O.$$

These substances separate upon distillation.

Propylic Alcohol.—Propylic alcohol, heated to 100° C. with bromine in sealed tubes, separates into two layers; the one consists of water holding hydrobromic acid in solution, the other of propyl hydrobromic ether and propyl alcoholate of propyl bromal. The propyl alcoholate of propyl bromal is a slightly yellow liquid, giving upon analysis figures corresponding to the formula—

$$C_3H_8O,\ C_3H_3Br_3O.$$

Butylic Alcohol.—Butylic alcohol submitted to the action of bromine under the same conditions gives a similar reaction, but the separation into two layers takes place after a more prolonged ebullition. The lower layer consists of water and hydrobromic acid; the upper of butylhydrobromic ether, butylalcoholate of butylbromal, and a non-volatile residue which carbonizes at a high temperature. The butylalcoholate was distilled by the author in a current of carbonic acid, and gave upon analysis numbers corresponding to the formula—

$$C_4H_5Br_3O,\ C_4H_{10}O.$$

In this distillation butylbromal was not obtained, and in rectifying under a pressure of 40 centimetres only the butylalcoholate separated.

Amylic Alcohol.—The reaction of bromine upon amylic alcohol likewise yields water charged with hydrobromic acid and a denser liquid. The latter consists of amyl hydrobromic ether, easy to separate by distillation, and a liquid which separates upon cooling after a portion of the ether has been distilled off. This liquid, mixed with sulphuric acid, was submitted by the author to distillation under diminished pressure, when a slightly coloured liquid passed over, which gave upon analysis figures that induced him to consider it to be a molecule of amylbromal, combined with one or two molecules of amylic alcohol.

JABORANDI AS A DIAPHORETIC AND SIALOGOGUE.*

M. Albert Robin has communicated to the Therapeutical Society (*Gazette Hebdomadaire*, November 20) an account of his investigations into the effects of this drug, in which he has been engaged in Professor Gubler's ward at the Beaujon. Under its influence the urea is at first diminished in quantity in consequence of the quantity of the urine being diminished; but after some days both these are increased, and the same may be said of the chlorides and the uric acid. This last has not been found either in the sweat or saliva, but the urea has been met with in the proportion of 3·12 grammes per litre. In a case of albuminuria the amount of albumen diminished during the first twenty-four hours from 17·20 grammes to 15·40; but the diminution was not permanent except in one case, in which it continued reduced from 14·40 to 12 grammes. The temperature increases in ten or twenty minutes, rising from 37° to 39° or 39·8°; the pulse also increases (from 96 to 105, for example). During the sweating the temperature falls to 37·7°, 37·6°, or 37·2°, and, when this is terminated, to the original 37°. For the next two days after the administration both pulse and temperature remain lower than the normal rates. When the sweating commences, "a true experimental asystolie" is produced, the tension diminishing notably; but next day the tension is reproduced and becomes sometimes more considerable than in the normal state. The *jaborandi* therefore seems to act on the vaso-motors, diminishing tension by paralysing them and facilitating the passage of the blood through the capillaries of the skin. In several cases in which it was given in minutely divided doses, there was neither sweating nor salivation, an abundant diuresis taking place, so that the urine increased from 750 to 1380 grammes. The effect of *jaborandi* on animals is very marked: guineapigs are seized with salivation, weeping, and diarrhœa, true ecchymoses being found in the intestines, and dogs become instantly salivated, their gastric secretion being also much increased.

M. Gubler observed that he had recommended M. Robin to employ the divided doses, in consequence of his having observed that diuresis occurred the next day or day but one after taking a large dose. He supposed that if the portion of the *jaborandi* which remained in the system after three days proved thus diuretic, this effect might be at once produced by giving small divided doses. A small quantity thus does not suffice for influencing vascular tension, acting only on the kidney. M. Gubler believes that the sweating determined by this drug depends upon the diminution of the tension which it causes, but that a complete equation cannot be established between this diminution of tension and the sweat. Another factor is the secretory irritation of the glands—an irritation acting on the kidney, and inducing diuresis.

* From the *Medical Times and Gazette.*

WILLIAM PROCTER, JUN.*

At the Semi-Annual Meeting of the Philadelphia College of Pharmacy, held September 28th, the "Committee on Deceased Members" presented an interesting memoir of the life and services of the late Professor Procter, whose death has already been recorded in this Journal. The memoir is too lengthy to reprint *in extenso;* but the following are the principal points:—

William Procter, Jun. (the "junior" being added to distinguish him from an uncle bearing the same name) was the ninth and youngest child of Isaac and Rebecca Procter. His father, who was a member of a Yorkshire family which had early associated itself with the Society of Friends, had emigrated from England while still a young man. William Procter was born in the city of Baltimore on the 3rd June, 1817. When from six to ten years of age he attended a Friends' school in Baltimore, taught by a lady of rare gifts and attainments. He was studious, gentle and companionable, and greatly beloved by his teachers and class-mates. His powers of observation were very early developed, and, as a child, nothing escaped his notice; he would interest other boys in stones that he would pick up in the streets, or in general subjects that would arrest his own mind. Mineralogy was his especial delight and study at this early age; while other boys would spend their weekly holiday in play, he would start early, with a lunch in his pocket and a steel hammer in his hand, and spend the whole day with a companion in the "quarries" north of the city, or in the "deep cuts" of the iron district, or at the "Bare Hills." The boys at school were always interested in his specimens, and many a young mineralogist received his taste and first lessons from this young teacher.

The husband of his eldest sister being disqualified by sickness from attending to his business—that of a cooper—William was at an early age taken from school to look after the affairs of his sister, and in the cooper's shop he acquired a knowledge of tools and a dexterity in the use of them which served him many a useful turn in after life.

Visiting Philadelphia with his mother, he became

* Abstract of a Memoir in the *American Journal of Pharmacy.*

acquainted with Joseph Turnpenny, who was then learning the drug business with the late Henry M. Zollickoffer at the corner of Sixth and Pine streets. Visiting the store with his friend, he found subjects congenial to his taste, and he determined to make that business the occupation of life. In 1831, at the age of fourteen, he entered the store of Henry M. Zollickoffer as an apprentice. Whilst in this position he received valuable counsel from his loving mother, the nature of which may be estimated from the following letter sent to him soon after his apprenticeship :—"Seventh month, 6th, 1831—I must tell my dear William how rejoiced I was to receive his very nice letter, not a single blot or mistake in it; continue, my dear boy, to be thus particular in everything thee does (I mean to do everything well), and I have little doubt thee will succeed in giving satisfaction to all with whom thee may have to do. Let it be thy study to endeavour to please (thy employer), not only when in the store about thy every-day business, but in everything. There are many ways of gaining the affection of those we are with by being kind and obliging to all, and if thee can lend a hand of help in any way, no matter how small the act is, never be backward, but with cheerful alacrity be always ready; this will cost thee very little, and by a kind and courteous deportment in the store and out of it thou wilt gain the love and good-will of all around thee. True politeness, my son, is a lovely accomplishment, but above all, never, never equivocate to screen thyself from censure, but if thou shouldst get into any difficulty be open and candid. Let honesty and integrity be visible in all thy actions, and thus, my son, I think, thou wilt never want a friend in man, and thou wilt have a friend in thy Heavenly Father, who can, and will, if thou love Him as thou ought, do more for thee than all the world beside. Therefore, my dear boy, 'seek Him now in the days of thy youth;' it is never too early to begin. There is another point on which I wish to remark—that of keeping everything thee may ever know relative to thy master's business entirely within thy own breast; sometimes by tattling or telling little matters to others it has often been a cause of a great deal of mischief and uneasiness, if not unhappiness; therefore thou wilt be guarded on this subject; never trust even thy own dear friends with anything relative to thy employer's business which thou might suppose he would not be willing for everybody to know; and always stand open to reproof; I have no doubt, if necessary, it will be administered in meekness and in love." The letter from which we have made this abstract, so replete with wisdom, is found among the letters which he preserved of that period.

From 1831 to 1836, he was quietly pursuing his duties as an apprentice, residing in the family of Henry M. Zollickoffer, his employer, endearing himself to all by his cheerfulness, brightness, and alacrity in all his duties. In 1836 he commenced a diary. In one of the early entries of this year, we find he records the death of his mother, at the age of sixty-three years. He says, "I have indeed lost another and only parent, who has watched over me with truly parental care and tenderness. All my hopes of repaying her unceasing kindness are now at an end, and all my dreams of pleasure about the days when I should become a corner-stone to her have vanished for ever."

In March, 1837, he passed a successful examination as a candidate for the diploma of the Philadelphia College of Pharmacy. The subject of his thesis was "Lobelia Inflata," a paper of great merit, in which he demonstrated the presence of an alkaloid, lobelina, on which the medical activity of the plant depends.

In May, 1840, he was elected a resident member of the College, and from that period the volumes of the *American Journal of Pharmacy* contained many contributions from his pen.

Whilst continuing unostentatiously in his position at Sixth and Pine Streets, his mind was keenly sensible to the deficiencies of his early education, and he strove by a diligent course of study and reading, to acquire a knowledge of the subjects kindred to his profession. His habit was to rise early, and devote the morning hours to his self-culture. 'Turner's Chemistry,' 'Ure's Dictionary,' and 'Dalton's Chemistry,' appear to have been his text-books. His custom was to keep notes of his reading, and indicate by signs whether a particular subject had been pursued to the satisfaction of his mind, or whether farther examination was desirable. His reading was attended with experiments in pneumatic chemistry, and an examination of the properties of the elementary substances. Electricity, galvanism, and electro-magnetism were attractive branches to him, at the time when Davy and Faraday were opening the portals which lead to a knowledge of these once mysterious agents of nature. He attended lectures given by Drs. Hare, Mitchell and Bache, in the winter of 1840, and expressed his gratification with Dr. Hare's experiments on electricity, and the solidification of carbonic acid, by Dr. Mitchell. He writes in his diary, "I obtained a piece of solid carbonic acid, and, returning home, repeated Dr. Mitchell's experiments on freezing mercury; my thermometer, after falling to —40°, suddenly contracted, and was frozen." He also constructed an electro-magnet, capable of supporting a one-fourth pound weight, and a table blowpipe to enable him to construct apparatus of glass.

In his twenty-third year, an offer made to him to enter into a chemical works in Baltimore was declined, and his engagement with Henry M. Zollickoffer was renewed. His leisure time was now divided between literary and scientific pursuits; his vacations, were occupied in occasional journeys for recreation and improvement. One note-book gives an account of a trip to Washington, and the country bordering the upper Potomac; another was to Ohio, returning by Niagara Falls; another by sea to Boston.

In 1841, he accepted the position of secretary to the committee on revision of the Pharmacopœia, and made numerous experiments for the committee, the chief of which were on the production of ether and Hoffman's anodyne. His first experiments on ether he records as failures; but says, "I have got on the track to obtain a good article of Hoffman's anodyne."

The years 1842 and 1843, continued his engagement at Sixth and Pine Streets. His leisure hours were improved by continuing his study of chemistry, taking up also botany, and learning the French language. General literature received considerable attention from him during this period. 'The Life of Washington,' 'Johnson's Life,' 'Alison's History of Europe,' and moral philosophy, are recorded as forming part of his reading. In 1842, he made a journey through central Pennsylvania to Pittsburgh, continuing westward as far as Cleveland. He returned by the way of the lakes to Niagara, then through the lake district of New York, and home, by the way of Elmira and Williamsport.

In February, 1844, he purchased the property at the south-west corner of Ninth and Lombard Streets, and commenced making alterations to render it suitable for a store.

We cannot do better than give his own recorded words at this important period, when about to embark in life on his own account:—"I am about to leave Sixth and Pine Streets, after so long a residence. What singular events occur! Little did such a prospect appear probable some years ago. Steadiness and calmness of mind, how important to the proper appreciation of life! This I daily become more convinced of, and find cause to note the want of it in my own case. Reflection steadily and calmly directed to moral and intellectual improvement, with all the rigour of justice, and all the affection of mercy. How few can truly govern themselves! I have made little progress in this all-important power, and have too frequent cause to regret acts of indiscretion and weakness."

On the 12th of May, 1844, he opened his store, and was behind his own counter. Long accustomed to the routine of an old-established business, he did not escape the trials which assail the mind while waiting for some indication of prosperity. Three months after opening his store, he writes, "It has been a time of singular discomfort to me, the anxiety incident to opening a new store, and the much time unemployed has been very burdensome. I need more faith and confidence in the course of events."

A circular issued on opening his store, bearing date Fifth month, 13th, 1844, says, "In reference to that important branch of the business, embracing the compounding of medicines and physicians' prescriptions, he believes that a regular education at the Philadelphia College of Pharmacy, and twelve years' experience in one of the first establishments of this city, will enable him to give satisfaction." The names of Drs. Wood, Bache, Jackson, Mütter, Hartshorne, Meigs, Harris, Rutter, and Henry M. Zollickoffer, are given as references.

The neighbourhood of Ninth and Lombard Streets, at that time, would not have presented many attractive prospects to the generality of beginners, so well qualified as William Procter, jun., for the higher branches of pharmacy. The square on the south side of Pine Street, between Eighth and Ninth Streets, was then an open lot. South street was the boundary of the city proper, and beyond this limit, for a long time, the acts of unrestrained "rings" of lawless associations presented but little inducement to a settlement in that part of the city of the well-to-do citizen.

Quietly, however, William Procter, jun., pursued his course, attending to his own business, and abiding his time. The unemployed time he speaks of, was far from being *misspent;* his active habits and inquiring mind were not content with waiting for the routine of counterwork. His attention was directed to the improvement of many of the formulæ of the Pharmacopœia, devising new preparations, and to original investigation on many subjects. As time passed on, the vacant lot was occupied by first-class residences, on Pine and on Ninth Streets. A consolidated police force restored order in the districts, and the business at Ninth and Lombard Streets began to assume proportions more befitting to the capacity of its proprietor.

Closely occupied during the day in the affairs of his business, he was always ready in the evenings to enjoy the society of his friends. Practical in his habits of conversation, a close and correct observer, well informed in all the branches of science which were allied to his profession, he was a pleasant and profitable companion. Naturally retiring, and somewhat reticent with strangers, he appeared to them grave and not susceptible to lively emotions; but to these who know where lay the secret spring which unlocked this exterior, the inner man was found with all the freshness of boyhood, and, with almost child-like confidence, his real life was spread before them.

There was no subject which enlisted his attention so much as the advancement of Pharmacy. The minds of many of the members of the College of Pharmacy had long foreshadowed the time when lectures on this subject would be added to the curriculum of the College. In 1845, the subject assumed a definite shape, by the presentation, at a meeting of the College, held in September of that year, of a memorial, signed by William Procter, jun., A. J. Duhamel and Edward Parrish, and accompanied by the following resolution, "That a committee of nine be appointed to consider the propriety of creating a new professorship, the occupant of which should be called the professor of theoretical and practical pharmacy." After an *animated* discussion (as the minutes inform), the resolution was adopted, Daniel B. Smith, then President of the College, acting as chairman of the committee. At a special meeting of the Board of Trustees in the following June, William Procter, jun., was unanimously elected Professor of Pharmacy.

In October, 1847, Mr. Procter delivered his introductory address to the class, which was published by request of the College. This address will be found in vol. xix. of the *American Journal of Pharmacy*, and will well repay any student of pharmacy for a careful perusal of it. The following extract which we make has not lost any of the timely words of warning then uttered. He says:—

"Some individuals enter the lists of pharmacy under delusive impressions, or are placed there by guardians who are equally misguided, illy prepared by education or endowments for so responsible a vocation. It is a sad spectacle to behold such giving their early years and youthful energies to a profession not suited to their tastes or inclinations—pursuing it, perhaps, until, on the threshold of manhood, when they find themselves about to be cast upon the ocean of society in a vessel with whose qualities and powers they are too slightly familiar to enable them to cope with the difficulties which assail them. Many who are unsuccessful as apothecaries might have arisen to respectability and competence in other pursuits more harmonious with their inclinations or natural gifts. It too often happens with these that, repelled by ill success from their legitimate calling, they are induced to bow before the image of empiricism in the hope of a golden reward, and prostitute that knowledge that they never should have acquired to the invention of nostrums, and forcing them into notice."

At the commencement of the course of lectures on pharmacy, there was some misgiving, in the minds of some students, whether they would find an equivalent for their time, and the money-cost of the course. Such, however, soon found that there was a science and method in the dull routine of even the mortar and the spatula which they had not dreamed of, and, by the time the course had ended, they discovered a necessity for the exercise of mental as well as manual dexterity behind the counter, if they purposed encountering an examination on their fitness to prepare and dispense pharmaceutical products.

In the preparation of his lectures no amount of labour was too great to deter Professor Procter from bringing before his class practical illustrations of his subjects; oral instruction he deemed very imperfect in his branch, unaccompanied by full demonstrations. This necessitated the expenditure of time and personal exertion which few could realize who were not conversant with his habits of thoroughness and conscientiousness in the discharge of his duty as a teacher. During several years of his professorship his health was not strong, but his active mind rose above his bodily infirmities, and made the physical subservient to the determined will which animated him. While aware of the necessity of taking care of himself, the severities of winter rarely prevented his being found at his post at the appointed time. He commanded the respect and affection of his class, and his opinions had a weight of authority with them which has rarely been disturbed by after experience.

In 1846 William Procter, jun., was associated with Professor Joseph Carson as co-editor of the *American Journal of Pharmacy:* for two years previously he had assisted Professor Carson in its editorial management. In 1850, Professor Carson resigned his position, and Professor Procter assumed the sole editorial charge. In 1853 the Journal was enlarged by the issue of six numbers annually in place of four. In 1871 the issue of the Journal was made monthly. Professor Procter inaugurated the monthly issue, and after editing the April number resigned his position, and was succeeded by Professor John M. Maisch. He had contemplated a relinquishment of his editorial duties for some time, and in a written communication to the College, some months previously, had advocated a monthly issue of the *Journal*, and requested to be relieved from the editorship as early as the College could find a suitable successor.

For twenty years the *Journal* had been under his management in its editorial department, and how successfully that management was conducted, the volumes issued during that period are the best testimony. The original matter from his pen, and his judicious selections, gave to it a value and standing among American pharmacists, and made it the most complete history extant of the progress of pharmaceutical science in the United States. As an editor, he was just to all contributors, pleasant in criticism, never indulging in the personal or sarcastic, ever ready to expose fraud and empiricism, loving truth and sometimes proclaiming it when it was a disagreeable duty. After resigning the editorship his time was so much occupied by his business that his name does not appear as a contributor directly to the *Journal;* in April, 1871, we have an article from his pen "On Pharmaceutical Titles" —the last of the long series. The general index of the *Journal* exhibits seven columns, numbering some 550 items, under his name, exclusive of extracts and editorials.

In October, 1849, William Procter, jun., was married, at Mount Holly, N. J., to Margaretta, daughter of Amos and Elizabeth Bullock.

During this year was issued from the press his American edition of Mohr and Redwood's Practical Pharmacy, enriched by additions from his own pen. The work never went through a second edition, attributed in a great measure to the cost of proper illustration, which the publishers were not willing to incur, and without which much of the value of the work would have been lost.

In October, 1851, there was assembled in the City of New York a convention of pharmaceutists, in pursuance of a call made by the New York College of Pharmacy, for the purpose of considering the law relating to the inspection of drugs at the Custom House, and to fix upon some standard which would enable inspectors to act with uniformity and discernment. This convention was impressed with the advantages which would be derived by the pharmacists of the United States from an association national in character, whereby, through personal intercourse and exchange of experience, the practice of pharmacy throughout the United States would be more harmonized and the general standard of education elevated. It was therefore "resolved that a convention be called, consisting of three delegates from each incorporated and unincorporated pharmaceutical society, to meet in Philadelphia on the first Wednesday in October, 1852." This convention assembled in the old College building, in Zane Street (now Filbert Street), and there was inaugurated the American Pharmaceutical Association, the President of the College, Daniel B. Smith, acting as its first presiding officer. From the time of its inception William Procter, jun., enlisted all his activity in promoting its welfare, and his name will be found in all its proceedings down to the meeting in Richmond, Va., in 1873. In 1852 he was a member of its first executive committee. He was corresponding secretary from 1852 to 1857, first vice-president in 1859-60, and was elected president at the session of the Association which convened in Philadelphia in 1862. In 1866 he was appointed one of the delegates to represent the Association at the International Pharmaceutical Congress to assemble in Paris in the following year. He was absent from the annual meetings of the Association but once (while in Europe), and contributed largely to the interest of its proceedings by answers to queries which he had accepted, and by his volunteer papers.

In 1859 Mr. Procter lost his wife, and in 1864 was married to Catharine, daughter of Robert and Sally Parry.

In 1866 he resigned the chair of Pharmacy, and was succeeded by Professor J. M. Maisch; an interchange of professorships was afterwards effected between Professors Maisch and Parrish, Professor Parrish taking the chair of Pharmacy, and Professor Maisch that of Materia Medica.

Many years of close attention to his varied and assiduous duties rendered a season of relaxation and change necessary. In the summer of 1867 he determined to take a trip to Europe. Leaving New York by steamer in April, he landed at Queenstown, and after a hasty run through Ireland he crossed over to England, and proceeded to London, and afterwards to the Continent. In the fortieth volume of the *American Journal of Pharmacy* is published his notes of travel, containing much interesting information to the intelligent pharmacist.

The business at Ninth and Lombard Streets increased with the progress of the city in that direction, and rendered necessary more ample accommodations. The first enlargement of his store was made in the winter of 1861, brought about at that time by an accident. He was distilling ether from a preparation, and having his attention called away, the water in the condensing apparatus became warm, and allowed ether vapour to escape into the store; mingling with the close atmosphere of the room, an explosive mixture was in time formed and ignited by the gas lamp under the still. The explosion forced the glass of the bulk windows into the street, but did no injury to the interior arrangements of the store, or to those engaged in it. Again, in 1870, more room was found necessary, and the whole of the remaining portion of the first floor was thrown into the store. In making these alterations, convenience for dispensing and proper arrangements for storage of articles was the first consideration, but little attention was given to the modern drawing-room style of some pharmaceutical establishments.

In 1847, Quevenne's Iron was introduced, and becoming popular, Mr. Procter devoted considerable attention to its manufacture, and produced an article which gained a high reputation in the market. The manufacture having been taken up by others possessing more room and greater convenience, he, after a few years, abandoned it.

When pepsin came into use, the varying qualities in the market induced him to make experiments on its production; he devoted considerable attention to it, and, during the last year of his life, he was quite extensively engaged in its manufacture. The subject of pepsin closed the last lecture which he delivered to the class.

In 1872 the chair of Pharmacy became vacant by occasion of the death of Professor Edward Parrish. The season for the opening of the course of lectures was so near at hand that the minds of the trustees of the College turned instinctively towards William Procter, jun., as the man to relieve them from embarrassment. The trustees were well aware that he had an earnest desire for retirement, and canvassed well the field for one who could, at so short a notice, take up the course on practical pharmacy. At the request of the Board of Trustees of the College he consented to fill the chair, and delivered the course of lectures in the winter of 1872-73. It was known to his friends that the position was intended by him to be but temporary, and that he contemplated retiring at the close of the following session. The lectures for 1873-74 progressed as far as February 9th, and but a few more remained to finish up the work which he intended should terminate his professorship. On the evening of February 9th he delivered his usual lecture, and on returning home expressed the great satisfaction which the attention of the class had given him. At a late hour he retired in apparently usual health; shortly after falling asleep, a disturbance in respiration aroused the attention of members of the family, and before medical assistance could be called, life had ceased. He died aged 56 years and 9 months, leaving a widow, and two children by his first wife.

In person, William Procter, jun., was of medium stature, with dark hair and black eyes, bespeaking an active, earnest mind. For many years after he commenced business his health was delicate, and fears were entertained that he laboured under pulmonary difficulties; such, however, proved not to have been the case, and the symptoms were probably connected with the incipient stages of disease of the heart, which finally terminated his life. His motions were quick, and evidenced the energy with which he was endowed. In manner he was unostentatious and retiring, but when he felt himself known and understood he was genial and playful. He was an observer rather than a talker, but possessed the ability of expressing himself in clear and pleasant language. As a lecturer he chose the didactic to the exclusion of the ornate style of speaking. The jewels of his character were integrity, sincerity, and a just sense of duty to his fellows. Educated in the religious belief of the Society of Friends, and holding their views during his life, he made no profession of sectarianism, but had an extended charity for the views of those who differed from him. Although he rarely alluded to religious subjects, those possessing his confidence were aware that the Bible had not been overlooked among his books. He was happy in the use of his pen, and his essays are marked by clearness of expression and a carefulness of detail, which leave no room to doubt the meaning of the writer. His investigations evidence a faithfulness in research and a completeness which has made his name an authority.

William Procter, jun., became a member of the Philadelphia College of Pharmacy in 1840; in the succeeding year he was elected to its Board of Trustees, and held that position during his life. In 1855 he was made Corresponding Secretary of the College, and continued to serve as such for twelve years. In 1867 he was elected first Vice-President of the College. His interest in the affairs of the College continued unabated during the thirty years of his connection with it; so closely was he identified with its progress, that its history during that period is almost a narrative of his life.

He served on all committees appointed for the decennial revision of the Pharmacopœia for the past thirty years, and his services were engaged in assisting Doctors Wood and Bache in several of the later editions of the United States Dispensatory.

A complete review of the published essays of Professor Procter would occupy too much space for this memoir, and we can only allude to a few of them. In his published thesis in 1837 on *Lobelia inflata*, he demonstrated the presence in the plant of an alkaloid, described the salts formed by union of the principal acids with the alkaloid, and proposed the name lobelina for the active principle.

Three years previously, S. Colhoun, M.D., Professor of Materia Medica in Jefferson Medical College, Philadelphia, published in the *American Journal of Pharmacy*, vol. v., the investigation of an acidified extract from Lobelia, which foreshadowed the presence of an alkaloid, but he did not succeed in isolating the principle. Professor Procter was aware of Doctor Colhoun's investigation, and referred to it in his supplementary paper, published in 1841, his not having done so in his thesis being, as he states, a "casual omission." In November, 1850, Mr. William Bastick read a paper before the Pharmaceutical Society of Great Britain on *Lobelia inflata*. He referred to Doctor Colhoun's paper, but evidently was not aware of Professor Procter's researches in 1837 and 1841. Mr. Bastick isolated the alkaloid, and described it, and his name is associated in the books with its discovery. In January, 1851, Professor Procter wrote to the Editor of the *Pharmaceutical Journal*, London, as follows:—"For some reason, these (my) essays appear to have been entirely overlooked by the press and writers on your side of the Atlantic, and now that the drug in attracting the attention of your medical men, its chemical relations are exciting the curiosity of your pharmaceutists. I should not have taken the trouble to bring their existence to your notice, had I not observed the paper of Mr. Bastick in your Journal for December, in which he states his ignorance of any previous researches having the same tendency as his own." The *Pharmaceutical Journal* then published Prof. Procter's essay, placing him thirteen years in advance of Mr. Bastick as the discoverer of lobelina.

In the same year with the publication of his thesis, we have "Remarks on an oil obtained by distillation from wild cherry bark, and evidences of its similarity to oil of bitter almonds." In 1838, a paper "Demonstrating the existence of amygdalin in several species of the genera *Prunus* and *Amygdalus*." In 1839, "Observations on dextrin and diastase," and "On *Lobelia cardinalis*," showing the presence in that plant of an alkaloid differing in some respects from the alkaloid found in *Lobelia inflata*. In 1840, a paper "On the power of saccharine substances in protecting from decomposition solution of protiodide of iron." In 1841, an essay "Supplementing his thesis on *Lobelia inflata*, and showing that the alkaloid therein described, represents the plant in medicinal qualities." In 1842, "Observations on the volatile oil of *Gaultheria procumbens*, proving it to be a hydracid analogous to salicylous acid." In 1843, "On the volatile oil of *Betula lenta* (sweet birch), and on gaultherin"—a substance playing a part similar to amygdalin—and which, by its decomposition, yields an oil identical with oil of gaultheria. In 1847, "On the reduction of oxide of iron by hydrogen." In 1849, "Remarks on the oleo-resinous ethereal extracts, their preparation, and the advantages they offer to the medical practitioner." In 1851, among numerous contributions, we have an essay "On the botanical and chemical character of sassy bark (the doom plant), of Western Africa." In 1852, a continuation of the essay on sassy bark, and "Observations on the volatility and solubility of cantharidin, in view of an eligible pharmaceutical treatment of Spanish flies." In 1853, fluid extracts began to attract attention, and in this and the succeeding year he contributed several papers on that subject; also, one "On the pharmacy of the phosphates." In 1858, "An essay on the hypophosphites." In 1859, "On polygalic acid," and "On the existence of nicotina in green tobacco." In the same year, he read before the American Pharmaceutical Association, in Boston, an elaborate essay on fluid extracts, suggesting formulæ for their preparation, and presented specimens of over thirty fluid extracts prepared according to his suggested formula. In 1866, we have an essay "On *Liquidambar styraciflua* and its balsamic resin," "showing the principle contained in the resin to be cinnamic acid."

The papers contributed by Professor Procter to the American Pharmaceutical Association are numerous, and marked by his usual carefulness and accuracy of investigation. Of these, his essay "On Ergot" (suggesting the use of acetic acid in its preparation), "On aconite root," "Atropia from American belladonna," "On extract of *Cannabis Indica*," "On *Sassafras officinale*," may be mentioned as not included in the preceding review. One of his latest papers was entitled "Suggestions to beginners in Pharmacy," and was reprinted in the last volume of this Journal, p. 974.

One of his last official acts before this in connection with the College, was in September, 1873, as Chairman of the Committee on Deceased Members, to read a memoir of their late associate, Elias Durand.*

Medical Evidence in Australia.—His Honour Mr. Justice Lilley, says the *Brisbane Courier*, during the hearing of the trial of the South Sea Islanders for manslaughter, gave a ruling upon a question in connection with medical testimony which has often cropped up in our courts. A chemist and druggist, Mr. Block, of Beenleigh, was called by the Attorney-general, to give evidence as to the cause of death; but Mr. M'Devitt, who was retained on behalf of the prisoner, objected to the question on the ground that the witness was not a properly qualified medical man, and that therefore his statement would be merely a matter of opinion, and would not, even if admitted, be of any weight. His Honour, in giving his decision on the point, held the evidence to be perfectly admissible, and said he wished it to be understood that he should never consider it necessary that witnesses giving medical testimony must be duly qualified medical practitioners; but in all such cases he should hold the proper course to be to examine the witness as fully as possible as to his experience in such matters, and then to let the evidence go to the jury for what it was worth.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 12, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DOCTORS AND DRUGGISTS.

THERE has been a time in the history of many social and political discussions, when the force of the arguments has swayed to one side, not so much because there has been any freshness in the arguments as because they have received the adherence of former opponents. Often such periods have been followed by a complete revolution in public feeling with respect to the particular question. The "no-popery" man of yesterday has to-day joined in abolishing religious tests; the protectionist has lived to expound the virtues of tree trade: until one wonders how with such a present consensus of opinion, the reform could have been so long delayed. One subject which has peculiar interest for the readers of this Journal appears to be now approaching a similar phase. Long have chemists and druggists been supplied *ad nauseam* by the medical journals with admonitory sermons upon the sacredness of medical ground, and the profanity of the chemist and druggist who approaches it with shoes either off or on. But there has been almost an entire ignoring on their part of all suggestions that proper bounds should be put round about the mount. Without putting it into so many words, the literary leaders of medical opinion have allowed it to be inferred that with respect to the callings of the doctor and the druggist, the former was at liberty to act towards the latter upon the principle—or *unprinciple*—of the old saying, "What's yours is mine, and what's mine is my own."

We are, therefore, glad to receive, almost simultaneously, two articles written so far apart as London and Montreal, and published in medical journals, in which a disposition is shown to discuss this question more impartially. The "faint and almost imperceptible line" which, in many parts of London, separates medical practitioners from druggists, is the theme of the *Medical Times and Gazette*. The evidence of the glaring lamp, the ostentatious display of diplomas—and, it might have been added, of druggists' sundries and patent medicines,—is regarded by our contemporary as demonstrating in many instances that the medical man has been impelled by the force of circumstances to lay aside the dignity of his profession and assume the position of a tradesman. The main excuse put forth in extenuation or explanation of this state of affairs is virtually the old one—

"Virtutibus obstat
Res angusta domi."

In this case the "straitened means" appear to be of two kinds, those of the practitioner and those of the locality by which he is surrounded. We only note this excuse to remark that, if available at all, it has a wider application.

If the method of obtaining a competence by the members of the medical profession must be "modified by their environments," chemists and druggists can hardly be expected to maintain a hard-and-fast line. On the other hand, if it be remunerative for practitioners dispensing from private surgeries to receive little, if anything, more for advice and medicine than would be paid for the medicine alone to a respectable chemist, there should be some margin of profit for the less expensively educated—but still respectable—chemist and druggist, whose charges are modified by his "environments."

En passant, we take exception also to the special application of a sneer of our contemporary at the enterprising young chemist, who gifted with a higher education than his predecessors, uses a "Greek compound," or "Greek and Latin conglomeration," to make his new combination pass muster with the drug-drinking public. It may have been temporarily forgotten that perhaps the most widely advertised instance of this kind is claimed as the invention of a gentleman whose name occurs in the Medical Register.

We are glad to find that the *Medical Times and Gazette* recommends the medical practitioner to withdraw as much as possible from this undignified contest of "pull doctor, pull druggist," and would look upon his victory in the contest as an unfortunate alternative. In that case it considers the taint would advance into higher circles; "men dispensing from private surgeries will extend their not uncommon practice of retailing drugs, and the good name of the medical profession in large towns will run the risk of being defamed by that familiarity which proverbially breeds contempt." We thoroughly concur in these remarks as being in accord with what has been repeatedly urged in these pages; and we believe that the medical profession would best serve its purpose in this matter by assisting to educate the public to draw a sharp distinction between the doctor and the pharmacist. Undoubtedly, as our contemporary remarks, the existence of the present state of affairs in the medical profession shows a "levelling down" which is in unfavourable contrast to the "levelling up" of pharmacy during recent years. We therefore rejoice that one leading medical organ at least should have the courage and wisdom to protest against medical men forgetting that they claim, by virtue of social position, by education, and by admission into a learned profession, to be superior to dealers in drugs, and that it calls upon them therefore to guard against that injury to the whole body which might easily accrue from "introducing a purely and ostensibly commercial element into the exercise of a dignified profession."

The other article we have referred to appeared in the *Canada Medical Record.* It owed its origin to local circumstances; but the underlying principle is the same as that affected in this country. Having come to the conclusion that reform is necessary, the *Record* proclaims that the physician and druggist should each work for one end: the one proving the therapeutic value of drugs, the other preparing them of such uniform quality and purity as to render observations made with them perfectly reliable. It therefore believes it to be the duty, as well as the interest, of medical practitioners to leave the latter portion of the work to the control of pharmaceutists, and thus to get rid of the onerous task of dispensing their own medicines. It points out that although it is impossible to combine both duties properly, there are men in Canada who practise as physicians and at the same time superintend drug stores. Such hybrid combinations are condemned as being injurious to both parties, and a hope is expressed that before long stringent means will be adopted to prevent them.

We cordially endorse these opinions, and share the hope of our contemporaries.

THE LIBRARY AND THE CONVERSATION ROOM.

It will be remembered that at the last meeting of the Council of the Pharmaceutical Society, a letter from the students at present in the Society's School of Pharmacy was read, asking that they might be allowed the use of a room in the building for the purpose of conversation and discussion on matters connected with their studies. The Council expressed its desire to accede to the request as far as the arrangements of the house would permit, and referred it to the House Committee to carry out the necessary arrangements.

We learn that the Committee has accordingly decided that on and after Monday next, the 14th inst., the Committee Room adjoining the Library shall be open for the purpose every evening from 5 until 10 o'clock, except on Saturdays, and that all persons connected with the Society, and all persons who have obtained permission from the Secretary to use the Library, shall have the privilege of using this Room. The Conversation Room, as well as the Library, will be under the supervision of the Librarian.

It has also been decided that in future the Library shall be open continuously from 9 a.m. until 10 p.m., daily, Saturdays excepted, when it will be closed at 2 p.m.

CHEMISTS AND DRUGGISTS' ASSOCIATION OF IRELAND.

We learn from an Irish correspondent that the chemistry class in connection with the above Society is now in full operation, under the able guidance of Professor Tichborne. A spacious room has been fitted up as a laboratory and lecture room, and contains all the necessary apparatus and conveniences. The classes meet on two evenings a week, viz., Tuesdays and Fridays, at 8 o'clock. Up to the present time more than sixty students have joined the classes, and it is expected that very shortly that number will be increased to about a hundred. Attfield's 'Manual of Chemistry' is the class book used in the chemistry class. The classes in botany and materia medica will not commence until February. Donations in the form of specimens, etc., will be very acceptable to the Society, and may be addressed to the Honorary Secretary, Mr. William Hayes, 12, Grafton Street, Dublin.

At the usual monthly meeting of the Society, held in the lecture room on Tuesday evening last, about twenty new members joined the Association.

EDINBURGH UNIVERSITY BUILDINGS EXTENSION.

An important meeting was held at Willis's Rooms, St. James's, on Monday last, for the purpose of making known in London a project for extending and improving the buildings of the University of Edinburgh, which buildings, in consequence of the widely extended area traversed in modern academic teaching, have become very inadequate. For instance, although the University of Edinburgh was the first British school to introduce practical instruction in Chemistry into the medical curriculum, no provision has yet been made for carrying on satisfactorily this and similar important branches of scientific training. His Royal Highness the Duke of Edinburgh presided, and stated that it was estimated that £100,000 would be required, towards which the sum of £70,000 had been subscribed, and he appealed for public support in providing the University with practical appliances for scientific research and instruction, so that it might be able to retain a foremost place among the educational institutions of the nation.

The resolutions were moved and supported by the Earl of Derby (Lord Rector of the University), Dr. J. Oswald Dyke, Professor Huxley, Professor Allman, Dr. Lyon Playfair, M.P., Mr. Hugh Matheson, Mr. Beattie, Mr. Cowan, M.P., and Sir J. Kay-Shuttleworth. Several large sums were subscribed at the close of the meeting.

The Duke of Edinburgh, who described himself as a matriculated alumnus and an Honorary Doctor of Laws of the University, amusingly illustrated the want of room in the lecture theatre, by narrating how on one occasion his hat was only by hasty removal saved from receiving the liver of a shark, under dissection by Professor Allman. Such a contingency, His Royal Highness seemed to think, would have been worse to endure than the smells produced by Dr. Lyon Playfair in his lecture theatre.

At a meeting of the Town Council of Dewsbury, held last week, Mr. F. M. Rimmington, of Bradford, Pharmaceutical Chemist, was appointed Public Analyst for that borough.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

December 8th, 1874.

Present—Messrs. Ainslie, Buchanan, Gilmour, Kemp, Kinninmont, Noble, and Young.

Professor Maclagan was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Two candidates were examined. Both passed, and were declared qualified to be registered as Pharmaceutical Chemists :—

Frazer, Samuel McCall .... Glasgow.
Currie, Robert Kirkwood............... Glasgow.

MINOR EXAMINATION.

Ten candidates were examined. *Six* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists :—

Edwards, Frank Dunn.................. Usk.
Cutler, William Herbert............... Bristol.
Cummings, Charles .... Glasgow.
Royse, John Frederick .... Stockport.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The following Certificate was accepted in lieu of this examination.

Certificate of the University of Glasgow.

McKenzie, Andrew .... Invergordon.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The second meeting of this Association (session 1874-5) took place in the large room of the Church Institute on the evening of Wednesday, November 11th, when, as on several previous years, it assumed a social character. Invitations were given to all the chemists and their assistants in the town, and were responded to by about one hundred, who sat down to a tea at half-past eight o'clock.

A number of microscopes and other scientific instruments interesting to the pharmacist, which had been kindly lent for exhibition by Mr. Fairley, the Borough Analyst, Mr. Pocklington, Mr. Abbott, Mr. Yewdall, and Messrs. Harvey and Reynolds, were after tea inspected with much apparent interest.

The President then, after welcoming the guests to the annual social gathering, delivered the following address:—

"Gentlemen, I congratulate you, as well as myself, that your Committee has been enabled to make such arrangements for our entertainment this evening, that it will be unnecessary for me to trouble you with any lengthened presidential address ; with your kind permission I will, however, venture to make a few remarks on one or two points which have suggested themselves to my mind. In the first place, then, let us ask ourselves, what is, or ought to be, the future work of associations like our own ? If we look around us towards the horizon of the pharmaceutical world, what do we see there ? 'A cloud no bigger than a man's hand !' For amongst the voices of the prophets, we may hear in accents louder than a whisper, 'The curriculum of pharmaceutical education is coming.' And the mouth which utters the momentous announcement is none other than that of Mr. Giles, of Clifton, seconded by our esteemed friend and neighbour, Mr. Siebold, of Manchester. Personally, I incline to the opinion, that taking the drug trade as a whole, and knowing that in country districts, and the poorer districts of large towns, the remuneration to be obtained by a chemist and druggist is but very small—I say I incline to the opinion that it would not be advisable to inaugurate so extreme a measure as that advocated by the gentlemen named. However, whether the little cloud grows larger, or fades altogether from our view, one thing is certain, scientific knowledge must be obtained somehow and somewhere, in order to pass the necessary examinations. Then I believe these local associations must become the centres for such educational means. Leeds already holds important advantages over her near neighbours. She is capital of the great West Riding of Yorkshire. Her school of medicine ranks high in the esteem of the medical profession. The recently inaugurated Yorkshire College of Science has its home, as you know, in our midst. Why should not Leeds also become the centre of pharmaceutical education for Yorkshire ? It is very likely that the College may materially assist towards such a settlement of the matter. Already it has its professor of chemistry, who delivers courses of lectures during the day, whilst our own able teacher, Mr. G. Ward, F.C.S., lectures to his students in the evenings ; and, although there will not probably be professorships in botany, materia medica, or pharmacy, yet I believe the Council would favourably receive any proposal from our Association, for the establishing of lectureships in such branches of science. Such lectures would doubtless have a certain prestige, and attract students to our town."

The President also made a few remarks on the recent controversy on Professor Tyndall's address at Belfast ; he thought the Professor had been rather hardly treated, considering his admission, "that beneath all there is a power perfectly inscrutable to the intellect of man."

Mr. Abbott followed with a short speech, in which he forcibly urged upon his hearers the value of a practical system of study ; and Mr. Ward and Mr. Brown, in proposing and seconding a vote of thanks to the exhibitors (which was carried by acclamation), vigorously put before the meeting the advantages connected with the Association.

A party of glee singers sang a selection of music at intervals during the evening, and contributed materially to the enjoyment of the meeting.

The third meeting of this Association (session 1874-5) was held in the library on Wednesday evening, November the 25th—the President, Mr. F. Reynolds, in the chair—when a paper was read by Mr. Jas. Abbott on "The Preservation of Syrups."

Mr. Abbott said the syrups of the Pharmacopœia included cane and grape sugars as preservative agents; all contained organic matter ; and organic matter was liable to change. He described the mode of germination and the whole life-history of Penicillium, Aspergillus, and Mucor, our commonest moulds, and illustrated them by diagrams and on the black-board. These, he said, were the cause of fermentation, etc. ; the spores were wafted about everywhere, and, if we could by any possible means keep them out of our syrups, we should be free from a great pest. It was false economy to use anything but the best sugar crystals in making syrups. They should be well boiled, put hot into clean small bottles, which should be filled to the lips, and the corks pushed in through the liquid. If stored in large bottles, the first time any was taken out, the enemy, fungus spores, etc.—mould—entered and luxuriated even in darkness : light not being required for their development.

He further said it is admitted that dark-coloured or opaque syrup bottles are necessary in our shops to hide from view their dirty insides ; midges, flies, mycelium, etc., being their constant occupants. He thought the old-fashioned teapot form of vessel for syrups was better than the modern bottle. With the former the syrup is poured from the bottom without breaking through the crust of flies, mycelium, etc. (though, of course, they should not be there). He also conceded that using from small bottles was better than from large ones.

A discussion followed the reading of the paper, in which the President, Mr. Thompson, Mr. Smeeton, and Mr

Brown took part; and a hearty vote of thanks was accorded to Mr. Abbott, on the motion of Mr. Jefferson, seconded by Mr. Hellowell.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Third General Meeting of the session of this Society was held in Anderson's University, on Wednesday Evening, 25th November, Mr. John Currie, President, in the chair. The lecturer for the evening was Mr. J. M. Milne, Ph.D., analytical chemist, who chose for his subject "Carbon and its compounds with Oxygen." He dwelt chiefly upon the nature and properties of the carbon monoxide and carbon dioxide, illustrating his remarks by experiment and otherwise. The lecture was most interesting and instructive, time alone preventing the subject from being treated so extensively as it might have been. At the close, on the motion of the president, Dr. Milne was awarded a very hearty vote of thanks for his able lecture. It was intimated that at next scientific meeting, John Dougal, Esq., M.D., would read a paper on "Zymotic Poison."

The society is reported to be in a most flourishing condition this session. The membership has already tripled what it was last year, and the meetings both of the association and the assistants' section are most enthusiastically and largely attended. An attractive syllabus has been issued, and upwards of thirty members are attending the tutorial class, conducted by Mr. R. C. Lindsay, B.Sc., and over twenty are attending Professor Dittmar's practical chemistry class.

A general meeting of the trade, under the auspices of the Society, is also to be held on the 16th December, to consider, firstly, the propriety of negotiating with the chemists of Edinburgh and other Scotch towns, with a view to having compiled a more extended retail price-list for the whole of Scotland; and, secondly, the effect which the present system of examinations and fees has on the supply of apprentices and assistants; and to consider a memorial proposed to be presented to the Council of the Pharmaceutical Society, praying them to alter and amend the regulations in relation to the same.

HALIFAX CHEMISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.

The inaugural meeting of the members of the above Society was held in the rooms on Friday evening, October 30th, when the following address was read by the President, Mr. W. Hollingsworth:—

Gentlemen,—It is my pleasing duty to congratulate you on the success which has attended the efforts of your Council. The reading-room is now, as you see, complete. The laboratory will be in operation in the course of a few months. Arrangements have been made for the conducting of a Latin class, which will meet for the first time on Monday evening next. Classes in materia medica, chemistry, and pharmacy will be commenced as soon as the laboratory is complete for their reception.

I have put together a few remarks for the benefit of those just commencing their studies.

On Study.

By study, I mean not a simple reading over of certain books and the learning off by rote of certain facts, but the earnest diligent perusal of the subject in hand, and when practicable, the verification of the statements made, whether in books, or *per ora*, by actual experiment. No student should accept anything on trust, but take the first opportunity of proving to the satisfaction of his own mind that the conclusion arrived at must be the correct one. Actual observation is of the utmost importance in those sciences with which we more particularly have to deal—chemistry, pharmacy, botany, and materia medica. A student may be fully acquainted with the number of the elements, their atomicity, the theory of atoms, and molecules, he may also have thoroughly learnt off by rote the characteristics of the various metals and non-metals, and yet not be able to distinguish potassium from sodium, nor a flask from a beaker. In botany he may be fully acquainted with descriptions of the various modifications of the root, stem and leaves, and the inflorescence. He may be well up in the characteristics of oxogens and endogens, and the essentials of the various natural orders, and, leaving out the actual examination and collection of plants, be in other respects a model student. But take him out into the fields, ask him to find you a plant, and refer it to its proper natural order; or, pull up a plant by the roots, and ask him to give you the name of that particular modification of root, and in nine cases out of ten he will not be able to answer you. The same in materia medica; he may be thoroughly conversant with the name, physical characters, and the natural orders yielding the various substances of which he has read—yet this will avail him nothing if he does not add to it the actual examination of authentic specimens. Now, suppose the chemical student had at once entered a well-appointed laboratory, and been set to work to make, say, hydrogen gas; he would have, first, the method of using the apparatus explained to him, and be told what materials to use; he would then proceed to the manufacture of the gas, and while this was going on, the teacher would take the opportunity of stating (supposing zinc and sulphuric acid to be used) that the experiment was an illustration of one of the modes of chemical action—the zinc displacing the hydrogen of the sulphuric acid, which was liberated as a gas, sulphate of zinc remaining in the bottle, and so on.

Thus, on the completion of his experiment, the student would not only have learned how to make hydrogen, but the use of the apparatus employed, together with the physical and chemical characters of the substances employed, and of the resultant compounds; and on reading up the subject afterwards he would more thoroughly understand his author, whilst the experiment would form a sort of nucleus round which his mind would cluster any further information and he might gather at any future time respecting hydrogen. These remarks apply equally well to the other sciences mentioned.

In my opinion, one-half of the failures in the examination result simply from the want of a well-directed system of study. Many students will work for three evenings, and sometimes a whole week, at one subject, and I know instances where one subject has been pursued, to the exclusion of all others, for two or three months. Now, suppose a student working up for the preliminary examination, sets to work at Latin grammar, and works at it continuously for, say, a week; the next week he works up his English grammar, and, the week after, arithmetic; at the expiration of the three weeks he comes back to Latin, and finds, to his astonishment, that the knowledge he had gained at the expiration of the first week has been pretty thoroughly crammed out of him by the pressure of English grammar and arithmetic. Nothing daunted, he sets to work again at Latin for another week, and then commences English grammar; here he finds that he is in exactly the same position in regard to this subject as he was with the Latin, yet not knowing how to account for the leakage of learning continually going on, he determines to work all the harder, figuratively "pouring water into a sieve." Here we have a thoroughly earnest and honest student who fails simply for the want of a system. He is, in fact, doing his best to cram out one kind of knowledge by the acquisition of another.

The system of study I would advocate is as follows:— First, in regard to the Preliminary students. The subjects required for this examination are, Latin grammar and translation, English grammar and composition, arithmetic, so far as concerns the first four rules, decimals and vulgar fractions, a knowledge of the metric system of weights and measures, and the First Book of Cæsar, 'De Bello Gallico.' We may place these subjects unde the respective heads of Latin, English, and Arithmetic; thus we have three subjects, and there are five evenings in the week on which the student may study. On Monday evening suppose he attended a Latin class. Tuesday he would devote entirely to the working out of the Latin exercises and the learning off of Latin grammar, etc., Wednesday would be devoted to the study of English grammar and composition, and Thursday to the study of arithmetic and the metric system. Friday evening he would have free for recreation, or for additional study in that branch of education in which he was most deficient. In this way he would go on, week after week, acquiring his knowledge little by little, and the intervals being short, he would not have time to forget anything he had learned before he again took up the same subject. The student should remember that Rome was not built in a day, nor is it to be expected that he will be able to pass his examination by a few months of Herculean study. By acquiring his knowledge in a slow and sure manner, small doses at a time, he has time to think over and practise what he has already learned, before it is crammed out by a fresh instalment. And, after all, this is the best and most expeditious method to adopt, and by degrees his mind becomes disciplined, his power of thought increases, and study becomes a pleasure. Moreover, he has the gratification of knowing that the result of his long course of study has not been the simple passing of an examination, but that the knowledge he has acquired, and the wholesome discipline which his mind has undergone, render him, in these days of the survival of the fittest, all the more fitted to carry on the battle of life. To those preparing for the Minor I would recommend a similar classification of their subjects, and urge on them the importance of not confining themselves to books, but of making their studies as practical as possible by a judicious blending of theory with experiment, and by endeavouring to demonstrate for themselves, as far as possible, the genuineness of the knowledge they acquire, thereby ensuring the success of their efforts. The student of materia medica should, whenever practicable, during the time he is reading up any given subject, have the actual specimen of the substance before him, so that he may examine it from time to time, noting the various characteristics which it is said to possess. No man can aspire to be a chemist who has not had a thorough laboratory training, and is not a diligent experimentalist. Similarly, no man is a botanist who has not gone out into the fields and visited the plants in their own homes; no amount of book learning can possibly make a botanist. The elements of botany should, if possible, be acquired in Nature's school, in order that the student may become a collector of plants before he is a student of their anatomy. We might as well expect a man to become an architect by studying the anatomy of bricks and mortar, and with as much reason, as we might expect the man to become a botanist who confined himself to the study of plants as depicted in books. Above all, the student should learn to apply his knowledge to the business in which he is engaged, whereby it becomes all the more firmly fixed in his memory, and by its application he gains fresh knowledge. What does it profit a man if he have all the knowledge in the world, if he cannot apply it in some way or other for the benefit of mankind? Like the miser, who takes a certain amount of money out of circulation, hoarding it up, he neither uses it himself nor allows others to do so; like the barren fig-tree, he only cumbers the ground. Every man has a talent given him, and woe to him who does not use it. Give me the man who can not only acquire knowledge, but use it. A man's life were indeed wasted if he did not leave the world, in some respect, better than he found it. Every man is not a genius, but every man has at least a mind, if he will only cultivate it. I will now conclude by exhorting all the assistants and apprentices of this town to avail themselves of the advantages which this Association offers, and, if they have not already done so, to at once commence to study in earnest, and, by their diligence and success, cause this Association to be known, not merely as an association of chemists' assistants and apprentices, but as an association of earnest seekers after knowledge, students in more than name.

Mr. A. G. Green proposed that the thanks of the meeting be given to the President for his able address.

Mr. C. Middleton said that the success of the members depended upon their individual efforts. There was a German proverb which said, "Every beginning is difficult, and the more excellent the task the greater the difficulty." Therefore he hoped that now they were commencing to study, they would persevere and endeavour to be successful. He had pleasure in seconding the vote of thanks.

Mr. M. F. Walton said that he could speak from experience of the benefits of a well-ordered system of study, and did not think he could improve upon the plan recommended by the President.

Some little misunderstanding having arisen on the part of the Chemists' Association, on account of a misconception of the attitude of this association, at a meeting of Council held November 4th, the President was empowered to treat with the Chemists' Association in order to settle the matter. A meeting of the Council was held December 1st, to receive his report of the action he had taken, and a copy of a resolution passed at a meeting of the Committee of the Masters' Association, received in reply to his communication, was presented. On the motion of Mr. W. H. Illingworth, seconded by Mr. A. F. Bottomley, the following resolution was passed, and a copy ordered to be sent to the hon. secretary of the Chemists' Association: "That this Council cordially agrees with the resolution passed at a late meeting of the Chemists' Association in reference to this association, and that it is their desire so to act as to merit the hearty sympathy and approval of their masters."

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 3rd December, 1874, Mr. W. H. Perkin, F.R.S., in the chair. After the usual business of the Society was terminated, a paper was read by Mr. S. Lupton on 'The Formulæ of the Alums.' The next was a note 'On the Colour of Cupric Chloride,' by Mr. W. N. Hartley, who finds that the crystals of the salt, when quite dry, have a blue colour, and not a green, as they usually appear when slightly moist. Papers were also read 'On the Oxidation of the Essential Oils, part II,' by Mr. C. T. Kingzett; 'On the Purification and Boiling Point of Methyl Hexyl Carbinol,' by Mr. E. Neison, and a 'Note on the Boiling Point of Methyl Hexyl Carbinol,' by Dr. C. Schorlemmer, F.R.S. The meeting was finally adjourned until Thursday, 17th December, for which date communications are promised 'On Groves' Method of Preparing Chlorides,' by C. Schorlemmer, F.R.S.; 'On the Precipitation of Metals by Zinc,' by J. L. Davies; 'Researches on the Paraffins existing in Pennsylvanian Petroleum,' by T. Morgan; and some remarks on the preceding paper by C. Schorlemmer.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of this Society was held on Wednesday, November 4, under the presidency of M. Regnauld.

A note was presented from M. Martin, accompanying a specimen of native sulphur from the Ottoman empire. M. Martin also presented a specimen of jaborandi from Brazil, which differed from that received from M. Coutinho, the radicles having a piquant taste analogous to that of radix pyrethri.

M. Husson sent a note relative to the alteration of iodide of potassium under the influence of sunlight. He proposed the addition to the starched paper of a small quantity of albumen, which would absorb the iodine in the event of the decomposition of the iodide by sun-light, and thus allow the action proper to ozone to be distinguished.

Eucalyptus as a Vermifuge.

M. Poggiale presented, on behalf of M. Vidal, a note on the vermifuge properties of essence of eucalyptus employed in the form of an enema. It gave the details of the case of a Zouave, who being afflicted with the presence of a great number of *Oxyuris vermicularis*, which all the ordinary vermifuges had failed to remove, was completely cured in nine days by using every evening an enema containing 50 or 60 drops of essence of eucalyptus to the quart. M. Mazet read a paper on the fermentation of currants in preparing the Codex "Suc de Groseilles," and the preparation of that juice.

False Opoponax.

M. Marais presented to the Society a specimen of false opoponax, composed entirely of myrrh. He stated that this gum resin, although little used in pharmacy, is at the present time much employed in Paris by perfumers. The consequence has been that the commercial stock has been exhausted, and the demand still continuing, it has given rise to the fabrication of a false opoponax from certain aromatic gum resins. The following tests are sufficient to discriminate between the true and false substances:—Upon incineration the true opoponax burns with a non-fuliginous flame, and diffuses an extremely pronounced odour of wild celery root; whilst the false gives off the characteristic odour of the gum resin or resin of which it is composed. If myrrh be used, it will, under the influence of the nitric acid vapour, acquire a beautiful rose colour; whilst opoponax, under the same conditions, does not change colour.

M. Bourgoin made known to the Society a new organic acid, dioxymalic acid.

Ceresin.

M. Guichard described some researches he has made upon the properties of ceresin. Paraffin has a crystalline texture, but ceresin and mineral wax are opaque and non-crystalline. Paraffin is soluble in ether, which only incompletely dissolves ceresin and vegetable wax. The residue presents the same appearance as the original substance, and melts at 80°, 85°, and 96°C., according to the degree of purification. From mineral wax may be obtained 23 per cent. of a carbide melting at 85°C. The soluble portion is paraffin. Some paraffin examined melted at 53°C., ceresin at 63°C., and mineral wax at 68°C. Neither mineral wax or paraffin is attacked by potash, and it only acts upon a portion (3 per cent.) of the ceresin. M. Guichard does not consider that these different products present any advantage over animal wax in the preparation of cerates. The absorption of water is difficult, if not impossible. But he thinks they would give to the vesicating plasters and the pomades a degree of hardness that would be valuable in the summer season.

PHILADELPHIA COLLEGE OF PHARMACY.

The first meeting of the present session was held October 20th, 1874, Mr. J. T. Shinn in the chair. Mr. W. McIntyre was elected Registrar.

Professor Bridges presented, in the name of Mr. A. Yarnal, some masses of sublimed bicarbonate of ammonia, which had been found in a barrel of the commercial carbonate lately purchased. This is an accidental product, rarely occurring in commerce. It was first noticed by Phillips, ('Annals of Philosophy,' xvii., 110), Henry (the chemist) having given it to him as an abortive result in a preparation intended for smelling salts. Phillips, on analysis, found it to be anhydrous bicarbonate, having the composition, as then expressed, of $NH_3 2HO.2CO_2$, the ammonium hydrogen carbonate of the new chemistry, $NH_4 H.CO_3$. This salt resembles the commercial carbonate in appearance, is hard, translucent and crystalline. After keeping it in a close bottle for some time a decided odour of ammonia is perceived when the bottle is opened, probably from the presence of some sesquicarbonate. This soon disappears, and, after exposure, becomes imperceptible. It has a pungent, saline taste, but none of the sharp biting of the sesquicarbonate. Exposed to the air it does not alter, but probably evaporates slowly; like all the alkaline bicarbonates, it holds, in the presence of water, part of its carbonic acid with a weak affinity. It dissolves, at 55° F., in six parts of water, and when a mass is placed in water minute bubbles soon form on the surface as solution takes place; these increase in number and size as the temperature rises, and become very copious at 150° F. The gas given off precipitates lime water freely. This solution of lime with an excess of the lime, when raised to the boiling point, does not affect moist turmeric paper placed in the mouth of the flask in which it is heated, showing that the gas is nearly all carbonic acid. The solution of the ammonia salt has also acquired a strong odour. This ready elimination of carbonic acid explains why solution of ammonia cannot be fully saturated with carbonic acid at ordinary temperatures. This salt, of course, is not proper for use as a stimulant, but, like the effloresced sesquicarbonate, may be used for other purposes for which the salt is adapted.

Mr. A. W. Miller exhibited oils of peppermint and lemon adulterated to a very large degree with alcohol and castor oil, and oil of wintergreen adulterated with alcohol.

Professor Maisch exhibited so-called American opium proved by Mr. Ebert to contain no opium, but to be probably extract of lettuce.

Dr. W. H. Pile briefly described the process for preparing bromide of ammonium, as reported by him to the American Pharmaceutical Association. The ammonia must not be poured down the same funnel as the bromine, but should be carefully distributed over the surface of the water, at the bottom of which the bromine is kept, otherwise reaction might take place with dangerous rapidity. In answer to a question by Professor Maisch, he stated that no bromide of nitrogen was produced.

Mr. Robert England exhibited some pictures photographed by the sun's rays, the natural colours of the object being fixed to some extent.

It was stated that sulphate of cinchonidia seems now to be used largely, and the good reports of its merits are substantiated.

Parliamentary and Law Proceedings.

Important Excise Prosecution of a Chemist and Druggist for Selling "Morning Tonic."

At the Hull Police Court on Tuesday, before T. H. Travis, Esq., Stipendiary Magistrate, William Staning, chemist, Cogan Street, was summoned by the Excise Authorities for retailing certain spirits, to wit, spirits contained in a certain compound called "pick-me-up," on the 1st of October, without his having a license to sell exciseable liquors.

Mr. F. Summers appeared for the prosecution, and Dr. Rollit, representing the Hull Chemists' Association, for the defence.

Mr. Summers said he was instructed by the Board of Inland Revenue to prefer the charge against the defendant, under the 6th George IV., chap. 81, sect. 26. The defendant was a druggist carrying on business in Cogan Street, and had latterly dealt in a liquor called "pick-me-up," which he (Mr. Summers) supposed was intended to be used by a man getting drunk over-night to "pick him up" in the morning.

Dr. Rollit (interposing): I beg your pardon, that is not the name. I am instructed not to take any technical objection, but I may say the name is "morning tonic." I don't know how the mistake has arisen of calling it "pick-me-up."

Mr. Summers continued, that if it were more agreeable he would call it "morning tonic," although it was actually known as "pick-me-up." A bottle of it was purchased by John Claridge, an excise officer, on the 1st of October, and it was handed over to his superior, Mr. Shawcross, who in turn sent it for analysis to London. The mixture was then found to contain 67·7 of proof spirit, and was flavoured with ginger, orange peel, and gentian. In consequence of the amount of proof spirit being found in the mixture, the Excise authorities had brought the case into Court. He should call the officer of the Excise who purchased the bottle, and the analytical chemist who had made the analysis, and he thought if he proved that the mixture did contain this large amount of proof spirit, the magistrate would have no difficulty in ordering a conviction. He was told that the gin and bitters sold by the publican did not contain more than 40 per cent. of spirit. In the event of this being so, the defendant would, he contended, be liable for selling spirit without a licence.

In reply to the Bench, Mr. Summers said his contention was that this mixture came under the statute as being British spirit. It was a British compound containing spirit, and flavoured with orange peel, quassia, and gentian.

The following witnesses were then called :—

John Claridge said : I am an officer of excise at Hull. On the 1st October last, I went to the defendant's shop in Cogan Street, and asked for a bottle of "pick-me-up" tonic. I was supplied in the bottle produced, and paid Mr. Staning 3*s.* 6*d.* for it. I took the bottle to the excise officer and gave it to Mr. Shawcross.

By Dr. Rollit : I could not say whether it was "morning tonic." I saw the label, but not until after purchasing the bottle. It was described on it as "morning tonic," but I asked for "pick-me-up" tonic, and I was supplied with it. I called more than once at the shop.

Dr. Rollit : The first time you called, didn't Mr. Staning tell you that he had none made ?—He did.

But you called a second time, and didn't he again tell you he had none made ?—He said he had not got it filtered.

Now, the third time when you called, didn't he fill the bottle for you ?—I do not think it was quite full.

I don't mean that—but did he make it up for you when you called ?—He went into an adjoining room.

Was he not absent a little time ?—He was.

And he brought the tonic from an adjoining room ?—Yes.

And for aught you know he may have had to make up the tonic for that special occasion ; he may have put it into the bottle ?—I can't tell.

At any rate, the bottles were not in the shop exposed for sale ?—I did not see any.

Now, did you ask for the largest size ?—I asked for a bottle of "pick-me-up."

Don't you know there were three sizes, one at 1*s.*, another at 2*s.* 6*d.*, and another at 3*s.* 6*d.* ?—I do not know.

Did you see the label ?—I had not seen the label at the time. I asked him what it was, and he said 3*s.* 6*d.*, and I paid him.

Have you not read the label, "In bottles 1*s.*, 2*s.* 6*d.*, and 3*s.* 6*d.*" ?—Yes, afterwards.

The bottle having been handed to the stipendiary, he asked : Did you see the cork ?—Witness : Yes, it was a plain cork.

Was it sealed ?—Not to my knowledge.

Did the defendant put any sealing wax upon it ?—I believe he did on the paper outside.

There was no seal on the cork ?—No, sir.

Then in point of fact the cork might have been put in at any time ?—Yes.

There was nothing to show that it had been put by for any length of time ?—No.

Mr. Summers: Can you say whether this is the cork put in at the time ?—Witness : I cannot say.

William Shawcross said : I received the bottle now produced from the last witness. He gave it me the same day that he purchased it, the 1st of October. I forwarded it to the Laboratory in London, addressed to the principal of the Laboratory, with the particulars of the case. I put it in a box, and sealed it up. The bottle is now in the same state that I received it, excepting that it was nearly full.

By Dr. Rollit : I believe the cork had no seal upon it. I think the same cork is now in it. I had the cork out several times, and I do not recollect any seal upon it. To the best of my belief there was no seal upon it.

Dr. Rollit : Assuming that this was a medical compound, I presume you would not think it was your duty to interfere at all ?—Witness : I am speaking now as an officer of Inland Revenue, and I do not think I am obliged to answer the question. If a person is selling spirits as we think illegally, we should interfere.

Assuming it to be a tincture, the Board of Inland Revenue would not interfere ?—If we interfere in any case, we must submit it to the commissioners, and ask for their decision.

Assuming this to be a medical tincture, you could not interfere ?—I did not interfere in this case.

If this is a *bonâ fide* medical tincture, the Board would not interfere ?—I should think not.

The Stipendiary : You would send it up and ask the Board instructions about it. You could not tell what the Board's decision might be ?—Witness : That is so.

Dr. Rollit : As a matter of experience you have not known of a case of interference with any *bonâ fide* medical tincture ?—Witness : I have never had such a case before as this is.

William Harkness was the next witness. He deponed : I am the analytical chemist to the Inland Revenue Board, and have been an analytical chemist for 13 or 14 years. The bottle produced I received into my possession on the 20th October last ; it was in a box, sealed. I may explain about this cork ; it was I who cut the top of the cork off. It is the same cork that was in the bottle in the box. By the direction of the Board I proceeded to make an analysis of the contents of the bottle. He found it to contain 67·7 per cent. proof spirit, and the flavour appeared to be derived from gentian, orange peel, and probably a little quassia.

Mr. Summers : From the result of your analysis will you state to the Court what is your opinion as to the mixture in that bottle ?

Dr. Rollit : I submit that my friend must put the question in some more definite form.

The Stipendiary : He tells us the particulars.

Witness : It is similar in every respect to bottles sold by publicans—a bottle of which I hold in my hand ; and is quite different from any "pick-me-ups" I have used.

Dr. Rollit : I submit the witness is not a medical expert ; he is not on the medical practitioners' list.

The Stipendiary : He is called to show what are the ingredients in this compound. I think what he has said so far is perfectly legal.

Mr. Summers : What is the usual quantity to be found in tinctures ?—Witness : Tinctures are generally made with proof spirit, and I have examined, in connection with this case, seven or eight samples, and have found them to contain 90 or 95 per cent. of proof spirit.

By Dr. Rollit : You say this tincture, as I venture to call it, contains 67 of proof spirit ?—It does.

So that it contains less spirit than tinctures usually do ?—It contains less spirit, but just the amount of spirit that public-house bitters do.

Now, you have referred more than once to public-house bitters ; don't you know as a fact that the publicans buy them of the chemist?—I don't know. They generally come from the rectifiers.

I suppose that probably both would be purchased from the same source?—Possibly.

Will you please give me your detailed analysis of the tincture?—67·7 per cent. of proof spirit, and the flavour appears to be gentian, orange peel, and probably quassia. I cannot give the exact quantities.

Can you tell me the names of any more of the ingredients?

In reply to the Stipendiary, Witness said: The amount of solids is only 3 per cent.; the amount of ash 3-10ths per cent.

Dr. Rollit: Do you say it probably only contains gentian, orange, and probably quassia?—One is in such a small quantity that I am not perfectly satisfied of its presence.

Dr. Rollit: Would you be surprised to learn that there are twelve or thirteen drugs in it—gentian root, camomile flowers, chiretta, coriander fruit, cascarilla bark, quassia, cardamom seeds, nutmegs, cayenne pepper, dried orange peel, cinnamon, calumba root, raisins and proof spirit?

Witness: If there had been raisins there I should have detected the sugar.

Dr. Rollit: You do not presume to say the medical attributes of each of these stimulants—

Witness (interrupting): I am not a medical man, though I examine these things for the medical profession.

What do publicans' bitters contain?—Generally proof spirits and one or two ingredients.

So that if there were the numerous ingredients of which I have spoken in this medicine that would distinguish it from the publican's mixture?—I found one publican who had six or seven different bitters.

You said, however, there was generally only one?—Yes, proof spirits and one or two ingredients.

Did you ever know a publican's bitter which contained some twelve or thirteen?—I have known one to contain five.

That is the largest number you ever knew?—Yes.

I want to know, if this contains twelve or thirteen ingredients; whether it will not lead you to modify your opinion that it is similar to the bitters sold by publicans?—Certainly not.

You have limited the publicans' bitters to contain only five ingredients?—In receipt books you will find far more than that number.

I want to ask you whether, if it contains more than twelve or thirteen ingredients that won't modify your opinion as to this being similar to the publican's?—It won't modify it unless I find the amount of each ingredient.

You say it is quite different to the "pick-me-ups?"—Quite different.

So that it is not like the publicans' bitters, and it is in itself a singular compound?—I said it was like the publicans' compound.

You have told us of other "pick-me-ups," just give me the ingredients.—Witness: The last I examined contained a large amount of sugar, glycerine, cinnamon, quassia, and 46·9 per cent. of proof spirit.

So that I may take it the average constituents of a "pick-me-up" would be about four ingredients, with a proportion of proof spirit?—Three or four ingredients; there may be more.

You have never met with a "pick-me-up" which contained some twelve or thirteen or fourteen bitters?—Never.

Are the "pick-me-ups" sold without the interference of the Board as medicines?—Some of them are sold as medicines.

The Board has not interfered in any case yet?—Up to the present time it has not.

Can you tell me what are the chief constituents of these medical "pick-me-ups"?—Quassia, gentian, and sugar.

So that the chief constituents of medical "pick-me-ups" are the same as this morning tonic?—Yes, except in larger quantities.

Can you tell me the detailed analysis of the residue of 3 per cent. of solids?—Oh no.

Supposing I found several chemists to tell us there was a much larger proportion, and they knew the ingredients, might that not lead you to modify your opinion?—If it were said of the same as I have examined I should certainly be astonished at it.

Some tinctures, I believe, are prepared with rectified spirit, which is still stronger than the proof spirit?—I do not know of any tinctures made with rectified spirit.

Supposing I were to name some to you, would you not be astonished?—I have not gone through the Pharmacopœia.

(The Pharmacopœia was here handed to witness, and looking at it, he was asked by Dr. Rollit): What is tincture of aconite?—That is rectified spirit.

Turn to tincture of arnica.—That is rectified spirit.—Turn to tincture of asafœtida.—That is rectified spirit.—Turn to tincture of Indian hemp.—That is rectified spirit; I confess I did not know this before.—Tincture of lavender which is sold every day over the counter, is not that rectified spirit?—I suppose it is.

Now, essence of ginger, is it not sold every day for domestic purposes; is it not used in every household?—It is not used in mine.

Is it not used for rheumatism?—I suppose it is.

Is it not used for flatulency?—I suppose it is; I am not a medical man.

Just turn to essence of ginger?—It is rectified spirit.

Then essence of ginger would contain a much larger portion of spirit than the tincture of which we are speaking?—It would.

I may take it as a general fact that the Pharmacopœia contains a number of compounds prepared in spirit containing a much larger proportion than the one now before us?—Yes.

So that the proportion of spirit in this tincture, if it be a tincture, is not excessive?—It is not.

So that practically that tincture is very far below the Pharmacopœia standard of spirituous ingredients of tinctures?—It is.

Dr. Rollit proposed to reserve his remarks for the present, and called—

Dr. Kelburne King, who said: I am a Fellow of the Royal College of Surgeons, and have been in practice for about twenty-three years in Hull. I am one of the surgeons in the Infirmary, have lectured in Hull on anatomy and surgery, and am President of the Hull Literary and Philosophical Society. I have been shown a bottle of this tincture.

Dr. Rollit: Would any man be likely to take it as a beverage?—Witness: I should think not.

Dr. Rollit asked his worship if he would taste the liquor?

The Stipendiary: I should be reduced to extremities if I did so (laughter).

Witness continued: The tincture is very nasty to the taste. A man would be very much depraved in intellect to take it as a beverage. It leaves a very nasty bitter taste in the mouth. I have had a prescription given me naming the articles in it. It has very much the same taste as the tincture of gentian of the Pharmacopœia has. It may be a little more bitter. From this I should say it contains more or less of gentian. There are other bitters I can detect—one of which I should think is quassia.

Do these appear to be in a small or large proportion?—Quite large enough to make it as strong a tonic as the tincture of gentian is. The proportion of spirit contained was rather less than that in the usual tincture of Pharmacopœia. It was a great deal less than one spoonful of lavender. It was about one-fourth less than a tincture prepared with proof spirit. There were many tinctures prepared with rectified spirit, which was considerably stronger; about 20 altogether.

Assuming this, Dr. King, to be composed of gentian root, camomile flowers, chiretta, coriander fruit, cascarilla bark, quassia, cardamom seeds, nutmegs, Cayenne pepper, dried orange peel, cinnamon, calumba root, raisins, and rectified spirit, *plus* water—how would that be described by yourself?—As a medical preparation, if medicinally prepared.

I ask you, Dr. King, is that what you would prescribe for any one?—I might; I am not bound to follow a prescription I do not know every particle of.

Might it not be prescribed with curative effects for any one suffering from certain complaints?—It might.

Would you prescribe it, or something of the same kind?—I would not prescribe anything, unless I knew every article in it and its preparations.

These constituents might be administered with advantage as a medical compound?—Yes.

Will you tell us any tincture in the Pharmacopœia to which it would be similar?—It would be similar to the compound tincture of gentian.

Have you any reason to doubt that these constituents are contained in that liquor?—I have not the least doubt some of them are.

Is the taste inconsistent with the presence of the whole?—It is not.

By Mr. Summers: I understand you to say that the contents of the bottle are similar to the compound tincture of gentian?—Yes.

Will you tell his worship what quantity of the compound tincture of gentian you would prescribe for a person?—That would entirely depend on the nature of the case.

As a morning tonic?—I don't know that I am particularly given to prescribing morning tonics. (A laugh.)

Don't you know the dose is from ½ to 2 fluid drachms?—It all depends on the case.

You have already said the contents of the bottle are similar to the compound of tincture of gentian, of which I am informed that from half to 2½ fluid drachms is a dose. Now, if you took two or three wine glasses per day from this bottle would it kill you?—No.

What would be the effect?—It would give you a very dry mouth and make you feel very disagreeable. (Reading from the bottle.)

Would you like to take a small wine-glassful at any time?—Certainly not, I don't say I would not prescribe it. You put the question to me, a person in good health; but to say I would not prescribe it under all circumstances is different.

Mr. Summers said the intimation on the bottle was "a small glassful may be taken at any time; or, mixed with a little sherry, it forms a milder but an agreeable tonic."

Mr. Travis asked what was a drachm?

Witness: A drachm is about a teaspoonful.

Mr. Summers: Would you recommend it to a sick or a distempered person?—Witness: There are diseases I would recommend it in.

Mr. Summers: Not to be taken in such large quantities as a wine-glassful?—Witness: I cannot say. It would depend upon the person for whom I was prescribing.

Mr. Summers: Would you think it a wise thing to give a bottle like this that a person might take it indiscriminately?—Witness: I disapprove entirely of medicines being sold to be taken at the discrimination of the person buying them.

By Dr. Rollit: Supposing the tincture of gentian were diluted with water to form a small wine-glassful, would it not have in it similar quantities to the tincture produced?—Yes, of the same strength, in reference to gentian, as the figure 3 to 4; so that an addition of the fourth part of water would bring the tincture of gentian down to the strength of this.

In that case a small wineglassful of the tincture of gentian would not be excessively diluted, as I suppose?—I don't think it would be excessive.

Have you any doubt, from the taste of that liquid, that gentian and other bitter tonics are largely prevailing?—Not the least.

Can you give me any idea of the percentage of solid matters?—The percentage of solid matter is very small.

Supposing it were present to the extent of some 3 or 4 per cent., that I suppose would be sufficient for its medical efficacy?—I should say so, if it were properly prepared.

Mr. Travis: You object to things of this kind being sold except under medical advice?

Witness: I, of course, disapprove of patients taking the law into their own hands.

Mr. Travis: Look at that bottle, we have had evidence that there is 67½ per cent. of strong spirit. Assuming you are not present, a person may take it as he likes?

Witness: I don't approve of their taking it at their own discretion.

The case was then adjourned, *pro formâ*, for a week, and then a day will be fixed for its conclusion.

Reviews.

SCIENTIFIC LONDON. By BERNARD H. BECKER. London: H. S. King and Co. 1874.

More than two centuries have elapsed since, in 1660, after a lecture in Gresham College by Sir Christopher Wren, then Gresham Professor of Astronomy, a number of gentlemen who had been accustomed to meet and talk over subjects connected with mathematical and physical science, resolved to form themselves into the association which survives to the present time under the honoured name of the Royal Society. But science has now become a domain far too vast for any society to attempt its exploration single handed; therefore, whilst in this country the Royal Society still devotes its attention to the investigation of the general principles of science, the working out of the details of the various branches of science has become the work of numerous institutions, each of which undertakes its special portion. Many of these, though not by any means all, have their seat in London, and they have furnished Mr. Becker with a topic for an extremely interesting little book, entitled "Scientific London," in which he has successfully attempted to supply a gap in the literature of science, by arranging, in a form accessible to the general reader, some of the scattered facts of their history.

The scientific institutions treated of in this book are fourteen in number, namely, the Royal Society, the Royal Institution, the Society of Arts, the Institution of Civil Engineers, the Chemical Society, the Department of Science and Art, the London Institution, the Birkbeck Institute, the Gresham Lectures, the Society of Telegraph Engineers, the Museum of Practical Geology, the British Association, the Statistical Society, and the Royal Geographical Society. We notice that no mention is made of any of the medical societies,—and perhaps consequently of the Pharmaceutical Society,—of the Linnean Society, the Royal Society of Literature, the Royal Microscopical Society, the Quekett, the Royal Asiatic Society, the Society of Antiquaries, and some other societies at least as important, in a scientific point of view, as one or two that are included. Of this, however, we make no complaint, for we should be unwilling to make room for them at the expense of any portion of the present volume; but we will express a hope that the author may have the opportunity and inclination to make them the subject of another.

Although Mr. Becker acknowledges the aid he has received from the officers of the various institutions, and some of the chapters evidence an intimate acquaintance with the history of the respective institutions, he has avoided a patchwork of different styles, by himself moulding the materials, and running through them a spice of individuality, which prevents them from becoming a dry record of bare facts. The general plan is to give a sketch of the origin of the institution, then of the work done by it and of the principal workers, and this is usually supplemented by a pleasantly written narrative of a personal visit by the author. Thus in the chapter on the Royal Society we get glimpses of Prince Rupert, Boyle, Wren, Newton, Hooke, Flamsteed, Halley, Gray, Banks, Wollaston, Davy, Brewster, and many others. Amongst the work of members of the Society in its earlier days, are mentioned the transfusion of blood, Newton's researches into the nature of light, the publication of the 'Principia,' Savery's engine to raise water by fire, a new-invented boat to be rowed with oars moved by heat, and Papin's digester. The author might have added, a paper on the production of perfect pea-fowl from barnacle shells. Further it would not be without significance to mention that so late as 1783, a Fellow of the Royal Society having asserted that he had accomplished the transmutation of mercury and other inferior metals into gold and silver, and being requested by his brother fellows to repeat his experiments, committed suicide by drinking laurel-water in the presence of three fellows who attended at his house for the purpose of witnessing them. This man, James Price, was the last of the English alchemists.

The chapter on the Royal Institution contains a sketch of the life of that remarkable man, Count Rumford, and shows how his effort to found an "institution for introducing and bringing forward into general use new inventions and improvements, particularly such as relate to the management of heat and saving of fuel, and to various other mechanical contrivances by which domestic comfort and economy may be promoted," has developed into one which will be for ever associated with the discoveries of Davy, Dalton, Young, Faraday, and Tyndall. On the other hand, the Society of Arts, founded originally to encourage young artists, has successfully carried out a scheme similar to that originally projected for the Royal Institution.

This will, perhaps, suffice to indicate the scope of the work under notice. But in order to give a specimen of the author's style, we quote his description of an evening at the Chemical Society, which also contains some reflections that will not be without interest to many of our readers:—

"The Chemical Society is one of those highly favoured bodies which, like the Royal Society and the Geological Society, are permitted to occupy a portion of Burlington House. A magnificent suite of rooms is allotted to it. There is a handsome library, admirably appointed, and enriched by a fine collection of chemical works, and regular files of English and foreign scientific periodicals. Adjoining the library is the inevitable tea-room, without which the domain of no scientific society is complete. Beneath these apartments is the great room of the society, fitted up with benches in ascending order, like those of an ordinary lecture-room. Behind a long table, more or less encumbered with chemical specimens and apparatus, sit the president and the two secretaries—the two latter gentlemen being charged with the onerous duty of reading papers in the absence of their authors. The presence of a number of ballot-boxes reveals the fact that several gentlemen recommended on the basis of "personal" or "general" knowledge are up for election; and the reception of many recently-elected Fellows, according to the form prescribed, indicates that the Chemical Society is adding largely to its list of members. This is a cheering sign, but my spirits are slightly dashed when I observe the extreme youth of many among the audience. As the names of the visitors—of whom each Fellow may introduce two—are read aloud, I find that their number does not account for the remarkable preponderance of young gentlemen. On inquiry I find that these must, therefore, be actual Fellows. I naturally experience some little surprise at this discovery, as I was once inclined—in the innocence of my heart—to attribute a certain distinction to the mystic letters F.C.S. Now, no human being is more inclined to encourage youth, and more disposed to regret its loss, than myself. It has long been an article of my creed that when a man is able to do good work, he is old enough to be entrusted with it, and I never lose an opportunity of insisting that in life the 'time' is not, as musicians say, 'taken quickly enough,' but I find it difficult to resist the conviction that many of the juvenile Fellows of the Chemical Society cannot possibly have attained any higher rank than that of students or of assistants to lecturers. I may be mistaken. The young gentlemen referred to may have attained eminence in the chemical world, or the letters F.C.S. may not be intended to convey any grave significance, but I confess that I am puzzled.

"Elections over, the reading of papers is proceeded with. Many of these are important, and a particularly interesting account of researches in Phenol is read by Dr. Armstrong, the chemical professor of the London Institution. Time passes quickly, and the attention given to the business of the evening is perfectly warranted by its engrossing character. Much revolving these things, I at length emerge into Piccadilly, admiring the youth of the Fellows of the Chemical Society, and wondering why a powerful body like this, possessing a fine library, has yet no museum of its own."

THE CHEMISTS AND DRUGGISTS' DIARY FOR 1875.

We have received a copy of this useful annual, which is doubtless now too well known to our readers to need any special recommendation. If it be granted that a Diary is a useful adjunct to the tradesman's counter, it necessarily follows that one drawn up with special provision for the wants of his particular calling wlll be a desideratum, and this object is fully attained in the Chemists and Druggists' Diary for 1875. Besides the usual sections of the Diary proper, there are included this year special articles on the Use of the Diary, Book-keeping, The Laboratory, County Court Processes, Aerated Waters, a Botanical Calendar, a Selection of Formulæ from the German Pharmacopœia, and other information generally looked for in almanacs.

BOOKS RECEIVED.

REPORT BY DR. M. C. COOKE ON THE GUMS, RESINS, OLEO-RESINS, AND RESINOUS PRODUCTS IN THE INDIA MUSEUM, OR PRODUCED IN INDIA. London: India Museum. 1874.

TRANSACTIONS OF THE ASIATIC SOCIETY OF JAPAN. Yokohama. 1874. From the Society.

Obituary.

Notice has been received of the death of the following:—

On the 21st October, 1874, Mr. Thomas Abson Nicholson, Chemist and Druggist, of Bradford, Yorkshire.

On the 27th October, 1874, Mr. Thomas Richardson Negus, Chemist and Druggist, of Manea, Cambridge.

On the 20th November, 1874, Mr. Alexander Stewart, Chemist and Druggist, of Milnathort, Kinross-shire.

On the 24th November, 1874, Mr. Henry Augustus Bolton, Chemist and Druggist, of Gateshead.

On the 29th November, 1874, Mr. Thomas Mayhew, Pharmaceutical Chemist, of Glastonbury. Mr. Mayhew had been a Member of the Pharmaceutical Society since 1842.

On the 30th November, 1874, Mr. Robert Waller, Chemist and Druggist, of Liverpool.

Notes and Queries.

[421]. SYRUPUS FERRI LACTO-PHOSPHATIS. —*A.* wishes to be supplied with a formula for Syrup of Lacto-Phosphate of Iron.

Correspondence.

Preservation of Infusions.

Sir,—In the discussion which followed Mr. Barnes' paper on the above subject at the last evening meeting of the Pharmaceutical Society, one of the speakers, enumerating several methods which had been tried, observes "they never were found to be very efficacious." Will you allow me one word in defence of an old friend there deprecated, viz., the process of boiling and tying over? It is adopted in many first-class provincial pharmacies, where the demand for infusions does not justify the daily manufacture of a supply of the infusions mostly in request, and where, unfortunately, the physician does not very frequently intimate to the patient that the medicine will take some time to prepare. Your readers are doubtless familiar with the process, which, if carefully conducted, rarely fails. It is easy, and necessitates no departure from the official formula. Some infusions so made were exhibited at the Norwich Conference, and, though six months old, were universally admired, and I shall be glad to show any one a rhubarb infusion eighteen months old as bright and free from deposit as on the day when it was strained into the bottle. To make any addition to official or private formula for the sake of convenience is the worst habit a dispenser can fall into. Who does not recoil from the introduction into infusions of such an element as chloroform? It would, even if sanctioned by the Medical Council, entirely alter the character of the preparation, and vastly diminish its value; for is not an infusion most frequently resorted to when there is a desire by the physician to avoid the stimulant contained in the tincture of the same drug?

THOMAS PERKINS.

Dover, December 7, 1874.

Sir,—I much regret that I am unable on account of distance from London to attend the evening meetings at Bloomsbury Square. I must say that I was surprised to find by last Saturday's Journal that gentlemen who occupy a high position as pharmacists should advocate the use of chloroform as a preservative for infusions, one gentleman gravely asserting (of course "cum grano salis") that two out of every three prescriptions contain chloroform. I find by my own dispensing book that chloroform and its preparations do not average more than about 8 per cent. It is well known that even in small doses in some diseases, especially in heart affections, its use is highly objectionable. By a very simple expedient all infusions (that of roses excepted) may be kept perfectly good for an indefinite period of time. Completely fill bottles, six or eight ounces are a convenient size, with fresh-made infusions, place them in a pan of cold water up to the neck, and bring to the boiling point to expel the air, immediately tie over with a double piece of thick tinfoil. I myself have kept infusions of senna, cascarilla, and others, if carefully prepared, perfectly fresh for three years, and if slightly warmed no difference could be noticed between them and infusions prepared an hour before.

OCTAVIUS CORDER.

London Street, Norwich,
December 9, 1874.

Amorphous Phosphorus.

Sir,—I am gratified to see that Mr. Greenish considered the purport of my letter to the *Pharmaceutical Journal* of sufficient importance to be brought prominently before the members present at your last evening meeting. My object in writing it will at once be apparent if your readers will turn with me to the correspondence (page 400, November 14th, *Pharm. Journ.*) relative to the discussion on my paper on "Amorphous Phosphorus," and they will there find the letter in which four questions are asked with a view to enable that gentleman to support his statement with facts as to dose, etc., this being most important in all cases of investigation where it is essentially necessary to reject "useless theory" and mere hypothetical "statements;" but I confess I am disappointed to find Mr. Greenish has not answered my plain questions in a plain and candid manner. I will therefore leave your readers to decide (on turning to my questions relating to the statements mentioned) what value to put upon the information given.

As workers in the cause of pharmacy, it is necessary to supply to medical men any form or forms required, and in the event of one or more not suiting the palate of a patient, to invent perhaps twenty others which will do so, and in this manner pharmacists may become, like Mr. Squire's book, important and useful, practical companions to the everyday life of the physician.

With your permission I should like to reproduce Dr. Attfield's remarks in the discussion at the evening meeting, and with his remarks I will be silent until I can submit the result of practical investigation.

"Professor Attfield said that amorphous phosphorus had been used in medicine some years ago, though not extensively, except by a few practitioners. He was informed by a person engaged in the trade, that though there was a considerable demand for it some ten or twelve years ago, it had lately been seldom required. At that time, however, therapeutists did not seem to know so much about the peculiar effects of phosphorus as they did now, when it was very generally prescribed, and therefore it occurred to him that with this increased knowledge therapeutists would be in a better position to test the qualities and medicinal properties of amorphous phosphorus. Very contradictory opinions had been expressed as to its physiological effects, and therefore it appeared very important that therapeutists should experiment with this powerful element in this particular form, and give the world the benefit of their experience. All experiments should be with red phosphorus containing no trace of ordinary phosphorus, or resulting observations would be valueless."

ARTHUR W. POSTANS.

35, *Baker Street, W.,*
December 8th, 1874.

Early Closing Movement.

Sir,—I have great pleasure in being able to say that the chemists and druggists of Bedford (a town of about 18,000 inhabitants) close their establishments at 7 p.m., except on Saturdays, when it is 10 o'clock, and do not open on Sundays; and close also on Bank Holidays. Most of them have three or four assistants, who take it in turns to stop in when shop is closed, after which time only medicine is supplied. On Sundays the one on duty stops in one hour in the afternoon, and from 8 to 10 in the evening.

The above plan has worked well for the last five years, so much so that all the other tradesmen have followed the example, with the exception of the tobacconists, etc.

A. W. WARING, A.P.S.

Dissatisfied Young Men.

Sir,—Contrary to the Rev. Dr. M'Auslane, and "A Dissatisfied Master," I do not think a man has reached a state of ineffable bliss when he says, "I have learned, in whatsoever state I am, therewith to be content." (I have often seen a fat, healthy pig look desirous of using such a phrase); moreover, it is pretty evident to any thinker that the amelioration of the "*désagrémens* incidental to the drug business," to living in closely populated countries, together with all moral, physical, and intellectual improvement, are promoted solely by dissatisfaction and a spirit of scepticism. Touching the vexed subject of early closing, it is worth while considering whether it is better to concede fair terms to our assistants now, or to wait until we are involved in the popular question of strikes.

We ask and expect higher education from our assistants, and it is simply justice to accord them definite and sufficient time for study and recreation—not to ask them to make "bricks without straw." When an assistant, I made ineffectual efforts to acquire sufficient knowledge to pass the Minor examination, until I found a master with a conscience, when I passed easily; there are many situated as I was, and want the same aid that I had.

In conclusion, I would ask "A Dissatisfied Master" to evolve from his inner consciousness an idea of what our world would be without dissatisfied people like himself.

GEORGE R. DURRANT.

Hertford, November 23, 1874.

Several other communications upon this subject have been received, which we are unable to print *in extenso*, but their tenour may be estimated from the following extracts:—

F. A. doubts the correctness of identifying the present generation of young men engaged in pharmacy with the class referred to in Dr. M'Auslane's sermons. The rev. doctor, in speaking of "the young men who lived in the great metropolis of the empire," said, that "they had health and strength, vigour and elasticity;" that "they were buoyant with hope," etc.; "they were with few cares, burdens, or trials." These characteristics *F. A.* considers to be inconsistent with long hours, small remuneration, stringent examinations, and the competition of co-operative stores.

"*Nemo*" says, that if "A Dissatisfied Master" is enabled to get comfort from Dr. M'Auslane's ministry, there are few assistants who are so privileged, and he fears they will fail to find any in the paragraph quoted. The comfort which "*Nemo*" thinks they would prefer is short hours, mainly that they may have a little time for study. He thinks the remuneration will be settled when there are more examined assistants.

"*Bristoliensis*" has forwarded a communication, in which he sketches the manner in which this question may be viewed from the masters', the assistants', and the neutral point of view. Although we are unable to spare the space for its insertion, we quite agree with him that the subject should be carefully viewed under every aspect.

We have also received a letter from an esteemed correspondent, under the signature "*Veritas*," which we purpose to print next week for the sake of the sketch it gives of apprenticeship in the "good old times."

Chemists and the Adulteration Act.

Sir,—Your leader of the 5th, on "Chemists and the Adulteration Act," though in the main excellent, yet in some points appears to have been written under a misapprehension, the correction of which is the object of this letter.

The "Society of Public Analysts" do not pretend, at this stage, to submit an absolutely authoritative definition of "adulteration" or of an "adulterated article," but they have endeavoured to express in tolerably comprehensible language the views which generally they hold.

The actual framing of a definition for the new Adulteration Act, if there should be such an Act, and if it should contain a definition, will have to be done by the authors of the Bill, who would probably confer with the Local Government Board, and if the co-operation and assistance of the "Society of Public Analysts" be then requested, they will be willingly rendered.

The Adulteration Act, 1872, contains no definition, strictly speaking, and the only legal guide which public analysts have had has been the well-known tea case in the Court of Queen's Bench, where it was ruled that any deviation, no matter how infinitesimal, from the standard of absolute purity should be deemed an adulteration.

Had this judgment been followed (and undoubtedly analysts and magistrates might have argued that it ought to be, seeing where it was given), the tradesmen, who, in their trade journals, as it is, are continually bewailing their lot, would indeed have had some cause to complain.

The public analysts, however, happening to be not only men of science, but men of sense, have given a considerable (I admit a variable) amount of "law," but their experience onvinces them that, in justice alike to themselves, the tradesmen, and the public, a definition of "an adulterated article" should be framed, and they presume to think themselves as competent to undertake the task as any other body of men.

Who, for instance, is so likely to know whether an article is "injurious to health" as the analyst?

Scarcely solicitors or magistrates, whose *forte* is law, not toxicology.

Surely not the manufacturers or vendors who have never made such a point their study, even if they feel any interest in it.

Certainly not the consumers, who, as a rule, know nothing about the matter.

Even the present Act therefore very properly assigned this duty to the analyst.

As to your objection to the term "sensibly increases,' your reason of objection is precisely my cause of defence, viz., that it does not tie the analyst down to report as adulterated an article containing some minute trace of foreign matter, but leaves him free to ignore any but an appreciable quantity, such as could be weighed or measured, and if the analyst be "sensible" there can be little danger in his being allowed this margin.

You next challenge the wisdom of making exceptions in the case of the presence of ingredients "due to circumstances necessarily appertaining to its collection, manufacture," etc.; but though the expression would doubtless leave room for argument, to have left it out would have been to rob the manufacturer of a safeguard to which he is fairly entitled.

I think it is idle to discuss the literal meaning of the word "adulteration," whether it includes substitution as well as debasement, impurity, corruption, contamination, etc.; and in the compilation of the definition we have declined to be shackled by the mere dictionary meaning, but adopting the view taken by the Select Committee have endeavoured to reduce to terms a "definition of adulteration" (or whatever other name you like to give it), which, if acted upon, will, we believe, at the same time, guard both the health and the pocket of the public, and the just interests of the honest tradesmen.

No one, except those who have been engaged in the task, knows the amount of labour it has taken.

Every effort has been made to obtain the soundest opinions, both chemical and legal, and though members of various trades would each like to see their own specially exempted, even some chemists, I believe, holding the extraordinary doctrine that the adulteration of drugs (but of course of nothing else) is a good thing; yet, on the whole, the Society of Public Analysts have all but unanimously accepted the definition as a "fair" one.

G. W. Wigner.

Erratum.—We are informed by Mr. J. B. Barnes that in the report of the discussion which followed the reading of Professor Godeffroy's paper "On an Additional Method of Testing for Glycerine," he is erroneously reported to have said "that there was an account contained last week in the *Daily News*, in the last article on the Exhibition, in which it was stated that glycerine was burnt for giving light." What Mr. Barnes said, was, that there was an account contained last week in the *Daily News* of the last English Arctic Expedition, in which it was stated that glycerine had been burnt as well as oil for giving light.

"*Student*."—The precipitate probably consists of a sparingly soluble compound of the quinine with the chloride of mercury.

F. C. S.—We will try to obtain the information asked for.

O. O. O.—According to section 12 of the Pharmacy Act, 1852, it is not lawful for any person, not being duly registered as a pharmaceutical chemist, to "assume, use, or exhibit any *name, title,* or *sign implying*" that he is so registered.

J. Simpson.—The arsenic in sheep-dipping compositions is generally combined with soft soap and potash. See an article by Dr. Macadam and Professor Gamgee in the first series of this journal, vol. xviii., p. 511, for precautions to be observed in the use of such compositions.

"*Query*" has forwarded, unaccompanied by his name and address, a series of queries, replies to which would involve an antiquarian research into the history of lac sulphuris. We must refer our correspondent to the rule respecting anonymous communications.

A.—Several formulæ for syrupus calcis lacto-phosphatis have already appeared in this journal. See vol. iii., pp. 559 and 570. Your other question appears on p. 578.

E. M.—See vol. i. (present series), p. 446.

J. T. Barrett.—Both your communications have arrived together, just as we are going to press. They shall receive early attention.

Communications, Letters, etc., have been received from Professor Tichborne, Mr. W. Baxter, Mr. Bennett, Mr. Ince, Mr. Bell, Mr. J. F. Brown, Mr. Postans, "Digitis."

ON A DRUG SUBSTITUTED FOR CHIRETTA (OPHELIA CHIRATA, GRISEBACH).

BY PROFESSOR BENTLEY.

Honorary Member of the Pharmaceutical Society of Great Britain.

A few days since a sample of Chiretta was forwarded to me by a well-known wholesale firm in London, stating that its genuineness had been called in question, and asking my opinion as to whether it really was the true herb.

Upon a superficial examination I found the sample to answer in colour and general appearance, as stated by the sender, the description of the official Chiretta pretty closely; but a practised observer would soon observe differences, more especially in the form of the stems of which the sample was composed, their less scarred character, and the less compact arrangement of the flowers and fruits, than in the true Chiretta.

When more carefully examined, several marked distinctive characters were noticed, the most important of which, in order to render them more evident, I have tabulated with the characters of true Chiretta as follows:—

Spurious Chiretta.	True Chiretta.
Stem obscurely quadrangular below, its four angles being each marked by a somewhat prominent border or wing; and very evidently quadrangular and winged above.	*Stem* round below and throughout nearly its whole length; and very faintly quadrangular above.
Leaves when present, sessile, narrow, and tapering to each end, that is, somewhat lanceolate in outline.	*Leaves* embracing the stem, broad at their base, and tapering upwards into a long acute point; that is ovate or cordate-ovate in shape, and acuminate-pointed.
Scars left by the fallen leaves, not very prominently marked, in consequence of the slight and comparatively narrow attachment of the leaves.	*Scars* left by the fallen leaves, very evident, opposite to each other and almost encircling the stem.
Flowers arranged in elongated loosely aggregated clusters, or cymose panicles. Flowers also larger and longer than those of true Chiretta.	*Flowers* arranged in less elongated cymose panicles, that is, more compact, and more umbellate.
A transverse section of the stem exhibits a comparatively thick woody ring on the outside; and with the centre hollow, or presenting but faint traces of pith attached to the inner surface of the ring of wood.	*A transverse section of the stem* exhibits a comparatively thin woody ring, enclosing a large continuous easily separable pith, which is yellowish in colour.

Such are the general distinctive structural and morphological characters between the spurious and true drug, which I have purposely given in as practical a form as possible in order to be readily available. Another very marked difference is afforded when we make an infusion of the two drugs. Thus, the taste of the infusion of true Chiretta is intensely bitter; and that of the spurious drug, although bitter, far less intensely so than that of the official drug. An infusion of true Chiretta has also a somewhat greenish tint, while that of the spurious drug has a distinctly yellowish-brown colour.

The question of the botanical source of the spurious drug now arises. It is well known that in the Indian bazaars several plants are known by the name of Chiretta, besides the true drug, and are used for the same puryoses as it. Thus, Royle, many years since, in his *Illustrations of the Botany of the Himalayan Mountains*, page 277, stated that *Ophelia angustifolia*, Don, is so used in Northern India, where it is called *Puharee* (hill) *Chiretta*, to distinguish it from the true or *Dukhunee* (southern) *Chiretta;* and he adds that *Exacum tetragonum* is also called *ooda* (that is, purple) *Chiretta.*

At least three other species of *Ophelia*—namely, *O. elegans*, Wight., *O. densifolia*, Grisebach, and *O. multiflora*, Dalzell; two other species of *Exacum*, as *E. bicolor*, Roxb., and *E. pedunculatum*, Linn., may be also enumerated; as well as *Slevogtia orientalis*, Grisebach, which is known as *Chota Chiretta* (small Chiretta), as being employed in India like true Chiretta.

The above-mentioned plants are all derived from the same natural order, Gentianaceæ, as that yielding the true Chiretta; but besides these, as mentioned by Royle, Waring, and other writers, another powerful Indian bitter—that is, *Creyat* or *Kariyát*, derived from *Andrographis* (*Justicia*) *paniculata*, Wall., of the natural order, Acanthaceæ, is also often confounded in Southern India with the true Chiretta.

It is somewhat surprising, considering the number of substitutes for the true Chiretta which are thus known in India, that some of them should not have found their way, accidentally or intentionally, into the English market; but no English writer of repute on the materia medica has hitherto noticed any such substitution. Even Flückiger and Hanbury, in their recently published *Pharmacographia*, say, page 393, "We have frequently examined the chiretta found in the English market, but have never met with any other than the legitimate sort." Moreover, beyond the case of false-packing described by Mr. E. A. Webb, in the *Pharmaceutical Journal*, vol. 1, third series, page 367, in which the roots of *Rubia cordifolia*, Linn. (*Munjeet*), had been enclosed in bundles of chiretta, I know of no published case of adulteration or substitution of true Chiretta in this country.

The botanical source of the present substitute of chiretta is, therefore, one of some interest and importance, and, upon examination, I believe it to be the sort of chiretta which, as stated above, is called in India *Puharee* (hill) *Chiretta*, and which is derived from *Ophelia angustifolia*, Don.; or if not from this plant, most certainly from a species of *Ophelia* very closely resembling it. Thus, it may be derived from *Ophelia pulchella*, Don. It is, therefore, closely allied to the true and official chiretta, which is obtained from *Ophelia Chirata*, Grisebach, and it possesses in some degree the bitter tonic properties of that drug. It is satisfactory to know that such is the case, and that, therefore, its use can lead to no serious consequences, but as it is very inferior in its bitter tonic properties to the genuine drug, it ought not to be substituted for it. I have, therefore, deemed it advisable to describe it at once in the *Pharmaceutical Journal*, and more especially so as there will be no Pharmaceutical meeting till February.

REMARKS ON THE JAVANESE CALISAYA AND ON CONCHININE.*

BY O. HESSE.

One remarkable circumstance connected with the results of cinchona cultivation in Java is that the *Cinchona Calisaya* grown there for many years, produces an important quantity of conchinine which is even relatively more considerable than in *Cinchona Pitayensis* and other cinchonas. It differs therein especially from the indigenous *Cinchona Calisaya* of Peru and Bolivia, the bark of which contains chiefly quinine, which is generally wanting in the Javanese Calisaya. If this difference be considered, together with the fact that a transformation of quinine into conchinine, or the reverse, does not occur either in nature or in the separation of these alkaloids from the barks, it may well be questioned whether this Javanese Calisaya be the *Cinchona Calisaya* of Weddell, or possibly, a distinct species.

I believe that I shall not be in error if I express the latter opinion. So far as can be judged, this species is not new—originating possibly in cultivation—but existed in South America prior to the transplantion of cinchonas from thence to Java. Evidently it was on that occasion taken for the true Calisaya. Hence it would obviously follow that the botanical characters of both species are either so alike or nearly alike, that the one species might be taken for the other. The only important distinction therefore was to be sought in the quality of their constituents.

This Cinchona is not to be confounded with that introduced into Java, through Ledger. That species yields a bark which in relation to its chemical constituents corresponds with the true Calisaya bark, and at the present time even exceeding it in the amount of quinine it contains. J. E. Howard named this Cinchona, under the first impression of these favourable results, *Cinchona Ledgeriana*. He considered it to be a variety of Weddell's *Calisaya*. Upon further consideration of the matter, however, it may yet turn out that the plant is no other than the true Calisaya, and that the large amount of quinine it contains may be the result of the great care with which the development of the Cinchona is at the present time observed and followed up in Java. At the commencement of the present year (1874), there were in Java 72,000 plants of this latter species. Among this large number of plants, some have become remarkable by the diversity of their botanical characters, as well as the quality of their alkaloids; whether this be a differentiation, which would indicate that the so-called *Ledgeriana* is a hybrid, or whether there is here a species invariable in its characters, has not yet been determined.

The amount of conchinine must be looked upon as characteristic of the original Javanese Calisaya. De Vrij, in 1859, separated this alkaloid for the first time from that Cinchona, and pointed out that what had hitherto been looked upon as a decomposition product of quinine was no doubt yielded ready formed by Nature. But the evidence was unsatisfactory, because at that time De Vrij knew too little of the properties of the more abundant alkaloids, and thus a confusion with some other alkaloid, possibly with cinchonidine or cinchonine, was not impossible.

This latter circumstance led me in a former communication upon the quinine alkaloids,† to make reference to that in the 'Jahresbericht f. Chemie' (1869), p. 940.

Upon this De Vrij gave me a specimen of the bark in question, from Tjibodas, that I might by an examination of the same satisfy myself of the correctness of his earlier observations. This investigation, carried out by a trustworthy method, gave with 100 parts of air-dried bark:—

		De Vrij found.*
Conchinine	3·18	0·50
Cinchonine	0·16	0·15
Amorphous Bases	0·77	3·60†
Quinine and Cinchonidine	0·00	
New Alkaloid	0·00	0·06
	4·11	4·31

The conchinine may be here regarded as a product of the oxidation of cinchonine. Though the chemical and physical behaviour of both alkaloids almost throughout suggest the near relations which exist between them, nevertheless the conversion of the one of these alkaloids into the other artificially has not yet been attained.

Recently Zorn has investigated conchinine in this direction.‡ This chemist obtained thereby a compound, which was represented to be constituted according to the formula, $C_{20}H_{23}N_2OCl, 2HCl$, and to have been formed by the substitution in the complex-atomic group of HO by Cl. Zorn considered it might be assumed that in this respect conchinine behaved in a manner analogous to cinchonine, cinchonidine and quinine. Unfortunately Zorn has neglected to ascertain what atom-group is capable of passing from the new salt into other combinations, and whether the water, which is represented in the formula given, actually exists. It appears to me that these new substances derived from cinchonine, cinchonidine, and quinine, are addition-products; so that Zorn's chlorcinchonid $= C_{20}H_{25}ClN_2O$, would be equal to hydrochlorcinchonin; presuming that it is not to be referred to cinchonicine. So far, however, as relates to conchinine the reaction takes place in a manner essentially different from the last-mentioned case. If sulphate of conchinine be treated with hydrochloric acid, according to the directions of Zorn, hydrochloric acid takes the place of the sulphuric acid, and we obtain a conchinine salt—namely, the bihydrochlorate. This salt forms fine colourless prisms, which by crystallization from moderately concentrated warm hydrochloric acid, may easily be obtained free from the least trace of adhering sulphuric acid. The crystals dissolve easily in alcohol, less so in water, hydrochloric acid, and chloroform. Their fluorescent aqueous solution gives, upon the addition of chlorine water and excess of ammonia, the well-known green colour. At from 100° to 120° C. this salt loses from 8 to 9 per cent., consisting of the water of crystallization and hydrochloric acid. The dried residue, dissolved in water, still has an acid reaction.

0·211 gram of air-dried substance, after being dried in

* *Annalen der Chemie*, vol. clxxiv.

† *Annalen der Chemie*, vol. cxxvi., p. 234.

* 'De Kinakultur op Java, op het einde van het jaar,' 1859 (Batavia, 1860), pp. 79, 94.

† These figures are the difference of 431 – (0·50 + 0·15 + 0·06). De Vrij does not state what he considered this quantity of alkaloid to be; but to judge from his communication to the *Pharmaceutical Journal* in the year 1864 (vol. iv., pp. 15, 50), it should be designated quinine, although no quinine is present.

‡ *Journ. f. prakt. Chemie* [2], vol. viii., p. 279.

the exsiccator (whereby no loss was occasioned), and being heated to 100° C., and afterwards to 120° C., until the weight remained constant, lost 0·0185, equal to 8·76 per cent. The residue was then dissolved in water, and the yet remaining hydrochloric acid precipitated with nitrate of silver, yielding 0·115 AgCl = 13·48 per cent. Cl. Then, since 0·2642 air-dried substance, precipitated with silver salt, yielded 0·188 AgCl = 17·59 per cent. Cl; there would be in the above case a loss of 17·59 per cent. less 13·48 per cent., or equal to 4·11 per cent. of Cl, or 4·23 per cent. of HCl. This gives for the water of crystallization 8·76 − 4·23 = 4·53 per cent.

The composition of our compound, therefore, answers to the formula $C_{20}H_{24}N_2O_2$, $2HCl + H_2O$—

	Required.	Found. Zorn.	Found. Hesse.
2Cl	17·11	17·02	17·59
H_2O	4·34	——	4·53

As a further characteristic of this substance, I may mention that the alkaloid, precipitated by ammonia, contained no chlorine after it had been crystallized from dilute alcohol. According to Zorn, it contains chlorine, but that chemist had omitted to purify his alkaloid by re-crystallization. This explains, probably, the difference in our results.

Zorn applies to the alkaloid he experimented with the name of quinidine. But as different alkaloids are understood under the name quinidine, I should not have ventured to substitute conchinine for that name had I not known that he employed sulphate of conchinine in the experiment referred to. This salt is very seldom met with in commerce at the present time; owing to the fact that the barks used in quinine manufacture—except the pitayo barks, which are becoming more and more scarce—contain an extremely small quantity, often mere traces of conchinine, so that the preparation of conchinine sulphate incidental to the manufacture of quinine sulphate has been almost entirely done away with. Notwithstanding this, a large quantity of "sulphate of quinidine" comes into the market; because it happens that in England, as well as in France and Germany, the barks now being used for manufacturing purposes are very rich in alkaloids which readily crystallize from ether, and from this portion of the alkaloid a sulphate is prepared, which in conformity to its origin is called "quinidine." But this "quinidine" consists in the main of cinchonidine, and only quite exceptionally contains conchinine. I mention this here, because many persons yet believe that the "sulphate of quinidine" of commerce is identical with sulphate of conchinine.

SOME PREPARATIONS OF ERYTHROXYLON COCA.

BY E. B. SHUTTLEWORTH.

Some time ago a sample of coca leaves, weighing several pounds, was forwarded to the writer, and was accompanied by a request that experiments should be made with a view of determining the most eligible form in which the drug might be administered. As the coca plant is coming more frequently into notice, and as its powerful remedial properties favour the idea that, sooner or later, it will be introduced into the materia medica, he has thought it advisable to offer a record of the result of these experiments, together with that of others made for the purpose of ascertaining the best formulæ for possible preparations of the drug.

In devising formulæ of this kind it is essentially necessary that the nature and properties of the active principle or principles of the drug operated upon be well understood. The literature of coca does not, however, afford information of as precise and thorough a character as might be desired, but, for practical purposes, it may, perhaps, be deemed sufficiently definite. Niemann* made a proximate analysis of the plant, and gives, as its constituents, a crystallizable basic substance (cocaina), a volatile, odoriferous substance, a peculiar tannin (cocatannic acid), and a waxy body termed coca-wax. Stanislas Martin† found a peculiar bitter principle, extractive, chlorophyll, a substance analogous to theine, and salts of lime. Maisch‡ was led to think that the leaves contained a volatile alkaloid. This supposition was subsequently confirmed by Lossen,§ who isolated this principle, and, at the suggestion of Woehler, who was associated with him in these investigations, named the new alkaloid *hygrina*. Lossen also found that cocaina, when heated with muriatic acid, was decomposed, benzoic acid and a new base, *ecgonia*, being produced. This fact operates against attempts to extract cocaina with acid liquors, and its importance was recognized by Lossen, who recommended the abandonment of Niemann's plan, in which acidulated alcohol was employed, and the substitution of infusion with simple water.

Thus far, then, we have as important and tolerably well established constituents of the leaves, cocaina, hygrina, cocatannic acid, coca-wax, and a volatile oil, to which the odour of the plant is due; of these, the first-named alkaloid is undoubtedly that to which attention should be principally directed in any attempt to make a preparation representing the active medicinal properties of the plant.

The characteristics and properties of the alkaloid may be concisely given as stated by Watts:‖ "Cocaina crystallizes in small, colourless, inodorous poisons; it has a slightly bitter taste, and produces temporary insensibility of the part of the tongue with which it comes in contact. It is soluble in 704 parts of water at 12° C. (53·6° F.), more soluble in alcohol, and still more so in ether. It melts at 98° C. (208·4° F.), and solidifies to a transparent mass, which gradually becomes white and crystalline. At a higher temperature a very small portion appears to volatilize undecomposed, but the greater portion is decomposed, yielding ammoniacal products. Cocaina dissolves without colour in strong nitric, hydrochloric, and sulphuric acid; the last solution becoming black when heated. It is strongly alkaline, dissolves in dilute acids, and neutralizes them completely." In most of its reactions cocaina resembles atropia, but that with carbonate of ammonia is different, and the melting points of the two alkaloids are not coincident. The formula assigned to it is $C_{16}H_{19}NO_4$.

Hygrina, the other alkaloidal constituent of coca assumes, at ordinary temperatures, the form of a thick oil of yellowish colour. It possesses a strong alkaline reaction, a burning taste, and an odour of trimethylamine. It combines with hydrochloric acid, forming a deliquescent salt. It is to some extent soluble in water, and dissolves readily in alcohol and ether. It does not appear to be poisonous.

Those points which bear directly on the subject of this paper, and which are embodied in the above particulars, are that coca contains two active principles on which its medicinal virtues depend; that one of these is mutable in the presence of acids, the other volatile, and, therefore, liable to be dissipated by heat; and that both are soluble in water and alcohol. We are not, however, informed in regard to the peculiar state of combination in which these alkaloids exist in the plant. That they are combined with some acid appears probable from the fact that the addition of a little lime, or other alkali, develops to a much greater extent the characteristic taste, and also the activity of the drug. This has been recognized for ages by the millions of persons addicted to the use of coca. Von Tchudi, Poppig,

Herndon, Weddell, and other travellers, affirm that in preparing the leaves for chewing, the addition of lime, *llipta*, the ashes of plants, as *Chenopodium Quinoa* or other alkaline substance, is generally made. A simple infusion is, however, often employed, and the full effects of the medicine appear to be realized from its administration. This is the oldest, and almost the only preparation of coca which has been used, and to this attention may, with propriety, be first directed.

Infusum Cocæ.—Take of coca, bruised, one ounce; boiling water, ten fluid ounces. Infuse in a covered vessel for one hour, and strain.

This preparation resembles in appearance and odour an infusion of ordinary green tea. Its taste is slightly bitter and alkaline, recalling infusion of spearmint. The benumbing sensation experienced when chewing the leaves is not so perceptible in this infusion. By applying to the dregs a slight pressure, about eight ounces of liquid may be recovered. Each ounce of the preparation will therefore be equivalent to a drachm of the leaves. The dose may be from one to two fluid ounces.*

Ext. Cocæ Aquosum.—Coca in moderately coarse (No. 40) powder; water a sufficiency. Macerate the coca with four times its weight of water for twelve hours, at a temperature not exceeding 120°F. Transfer to a percolator and exhaust with water. Evaporate by means of a water bath, to the consistence of an extract.

The extract thus prepared is of a dark brown colour, and bitter but not very characteristic taste; 100 parts of leaves yield 36 parts of extract. The dose may be from 15 to 30 grains.

Ext. Cocæ Alcoholicum.—Coca in moderately fine (No. 50) powder; alcohol, sp. gr. ·838 a sufficiency. Moisten the powder with alcohol and pack tightly in a percolator. Add alcohol, and continue the percolation until the powder is exhausted. Evaporate the percolate by means of a water-bath, at a temperature not exceeding 150°F., until the extract is of proper consistence.

This extract is much superior to that prepared by water, possessing, in the highest degree, the characteristic taste and odour of the plant; and as far as I have been able to ascertain by experiments upon myself, possessing also in full its medicinal properties. It is of a green colour, resembling extract of Indian hemp, and is apparently resinous in character. This characteristic is attributable to the coca-wax or other concrete oily substance with which the extract is mixed. When exposed to the air the extract does not harden, but slowly attracts moisture, becoming, in time, quite liquefied. I regard this extract as one of the best forms in which coca can be administered. It can be readily formed into pills, and is perfectly reliable. The product from 100 parts of the leaves is 15 parts of extract. The dose may be from 10 to 20 grains.

Ext. Cocæ Fluidum.—I have not had time to experiment upon this preparation, but would suggest, as a menstruum, alcohol of sp. gr. ·835 or ·838; the reservation of a portion of the percolate equivalent to three-fourths of the weight of the leaves employed; and evaporation of the remainder, at a temperature not exceeding 150° F.

Tinct. Cocæ.—A tincture containing four ounces of coca to one imperial pint of proof spirit or diluted alcohol may be prepared by percolation, but such a preparation does not appear to be advisable or necessary. The large quantity of alcohol which each dose would contain might entail therapeutical complications which it would be well to avoid. For administering the drug in a liquid form the infusion will be found as simple and reliable as any, and, by the addition of a small quantity of alcohol—say one-eighth part—it might be preserved from change for a reasonable length of time.

* A description of the therapeutical effect of coca does not properly come within the limits of this paper. But for information regarding the remedy as administered by infusion, the reader is referred to a Prize Essay on the subject, written by Dr. Mantegazza, of Milan, and of which abstracts may be found in the *Pharm. Journ. and Trans.*, 1860.

MERCURIAL POISONING FROM THE USE OF PINK AND RED VULCANITE IN ARTIFICIAL GUMS.

In the *Medical Press and Circular* for December 9, Dr. W. Bathurst Woodman records several cases where patients have shown symptoms of mercurial poisoning for which he could find no other explanation than that they were wearing artificial gums, or artificial palates coloured with vermilion. Upon inquiring carefully he found that very large quantities of this material are manufactured, and that in past years, at least, dentists of the highest respectability, and in various parts of the kingdom, as well as on the Continent, have supplied their patients with this *matériel vraiesemblant*, which is not always vulcanite. He examined specimens of various depths of tint, from varying proportions of vermilion; and of varying hardness, some of the cheaper kinds being simply blanched gutta-percha incorporated with cinnabar. The results of his examination and experiments are as follows:—

(1). All the pink and red artificial gums, palates, and materials for the same examined contained vermilion.

(2). The quantity of vermilion present was not always proportionate to the depth of tint. Some of the most beautiful and natural specimens contained the pigment rather in a state of very fine division than in any great quantity.

(3). As the temperature of the mouth seldom exceeds 37° or 38° centigrade, and saliva is a very dilute solution of the saline substances it contains, the possibility of the warmth of the mouth, and the action of the saliva, or of articles of food, producing volatilization or solution of the pigment has been questioned. Dr. Woodman believes, however, that poisoning occurs in both ways, and possibly by a third method—viz., by conveyance to the stomach, along with the food ingested, of minute particles worn off in the process of mastication. As regards the first method, or volatilization, he satisfied himself by delicate methods of analysis that nearly all the mercurial compounds are somewhat volatile at lower temperatures than 98° or 100° Fahr.

He also remarks that lead, arsenic, and numerous other bodies, in forms not usually deemed volatile, are so in a slight degree, as proved by continuous observation at ordinary temperatures, a fact well known to chemists. But he has found that the prepared rubber, or tinted vulcanite, *slowly gives up its mercury* (which is only mechanically mixed with it), both to saliva and to an artificial solution made to imitate it with common salt, sulpho-cyanide of potassium, etc., at 60° Fahr., and more quickly if the solution be kept at 100° Fahr., and the metal can be easily detected by electrolysis, as well as by other tests. This solution may be hastened by agitation. Solutions of several of the haloïd salts have similar solvent properties.

(4) In answer to the possible objection that although this solution goes on slowly, yet the constant washing of the artificial gum or palate would really prevent the occurrence of mischief in the human body. Dr. Woodman narrates three or four out of about a dozen cases observed by him from the year 1862 up to the year 1873, in which once rid of the corpus delicti, the red gum, not of Australia nor of the nursery, but of the dentists, the patients rapidly recovered. "*Tollitur effectus, sublatâ causâ.*"

(5) The saliva and urine in some of these cases contained minute but unmistakable traces of mercury, every possible precaution being taken to avoid known and probable sources of fallacy.

After describing the cases, Dr. Woodman says, "I think few candid persons will doubt that in some cases, perhaps more numerous than we now think, severe effects follow the continued use of artificial gums, palates, and teeth-plates coloured with mercurial pigment. The amalgams used by some dentists may produce similar symptoms. The question is one which I think well deserves the attention of scientific dentists and chemists. I write on it as a practical physician; and as my cases extend over nearly twelve years, I do not think I have displayed undue haste in doing so. There is some danger now of arsenical, lead, and chromium pigments being substituted, and toxic symptoms, due to these metals rather than to mercury, may possibly have been noticed in some cases. A dental student told me that herpes labialis is unusually common in those who wear false teeth; but this may possibly be due to mechanical irritation only. Well-fitting teeth are otherwise so desirable that it would be well to devise and employ some pigment of a natural colour which should be free from the objections attaching to all the metals I have named.

DR. CLELAND ON THE RELATIONS OF SCIENCE TO PHILOSOPHY.*

The following is a portion of an introductory lecture delivered by Professor Cleland to the students attending the classes of Anatomy and Physiology in the Queen's College, Galway, at the opening of the winter session:—

Gentlemen,—In welcoming my pupils to their studies at the commencement of a new session, I own that I feel more impressed every year with the gravity of the circumstances in which they are placed. I shall not occupy your time with moral reflections on that subject, but shall content myself with observing that, even surveying your position with the utmost seriousness, it is impossible for you to appreciate at present the consequences to yourselves in after life of the manner in which you dispose of your time in your four years of study, as you will appreciate it when the time is past, and you begin to reap the results of a well- or ill-spent college career. Four years is but a short time to learn all that you ought to know before entering on the practice of your profession, and all that you will wish that you had learned when in after life you look back on your student days. Remember that what constitutes learning in a practitioner of a scientific art is the intimacy of his acquaintance with the sciences on which his art is based. To be worthy, then, of holding a high position, you must give all your energies during your student days to your scientific studies. I should be sorry indeed that your literary education should be neglected. I think it a sad mistake for any student to be hurried into medical classes without a general acquaintance with languages, mathematics, and physics; but the time for literary studies in your case is in the first place, and principally, before you begin your medical studies, and afterwards as much as you like when your medical curriculum is completed. They may even be advantageously attended to in holiday time; but devotion of time and study to literature during the sessions which ought to be given up entirely to your professional education is always injurious. Those of you who are commencing their medical studies are about to engage probably for the first time in scientific pursuits; and these differ widely from your studies hitherto, both in their matter and their methods. It is no longer principally memory on which you are to rely, but observation. You will find in science that it is little matter what this or that authority has said, or what the words in which he has spoken—Nature is to be your authority. You must observe for yourselves in every instance in which you have the opportunity; and, both in your own observations and in judging the statements of others, you have to learn by great care and practice to distinguish accurately the phenomena observed from the translation given to them—an art which perhaps to you at the outset may appear easy, but which I have learned to believe is never perfectly mastered.

And now I wish to say a few words about the relations of the sciences to philosophy, and to your future career.

Life is a voyage on which we enter without any will of our own, and in which we gradually wake to find ourselves on a stream not of our own selecting; with scenes around us, not of our own choice, carried by currents not of our own creating, but through which we have a certain limited power of steering, sufficient, at least, to enable us to profit by many lessons of experience, and avoid numerous dangers. This is that voyage of life in which men continually awake to ask the questions, whence have we come? and whither are we bound?—questions of the most gigantic and important description of any which directly interest humanity. It may naturally occur to you to ask what are the relations of science to those questions; and I do not think that I shall be travelling out of my proper domain to devote some part of an introductory lecture to put that matter justly before you. Science, if we consider the word merely from an etymological point of view, may be considered to include all methodized search after truth of whatever description; and it appears to me that this circumstance has often misled some of its more noisy and less judicious votaries and on-hangers into arrogating for that which is in the present day called science, a title to deference in domains beyond its sway. It ought not to be forgotten that the term science, as the word is now used, includes only those branches of research in which the data are matters of observation. And I may remark further, that every science consists of two stages of different dignity—viz., the collection of data, and the formation of laws and doctrines therefrom. Thus, in philology the data consist of observations on languages and dialects, whence laws are evolved as to the changes to which words are subject, and doctrines as to the affinities of different tongues. In chemistry observations are made on the percentage composition of bodies, the proportions in which they combine with others, their crystallisation, and so forth; and conclusions, often of a most deeply theoretical description, are arrived at with regard to their constitution and the laws which regulate chemical combination. In physiology the component parts of living bodies are observed in action, the variation of their structure in different circumstances, and the chemical composition both of the parts themselves and their products are investigated, also the effects of external agents on them, and the influence on the body of removal of portions; and from the collection of such inquiries is built up all our information of the use of organs and of the laws of life as exhibited in the individual. Anatomy consists largely of an observational part which is of most importance to medical students. But in this science also there is a higher department; and he who looks on the mere gathering of material for the use of the physiologist, the surgeon, and the physician, as including the whole scope of the study, has but a very meagre and imperfect knowledge of that science whose business it is to investigate the laws of organization—a science which, more than any other inquiry in the domain of nature, affords evidence of a mighty intelligence as Creator. I allude to that department of anatomy specially designated as morphology or philosophic anatomy; and this brings me to my next remark. For in philosophic anatomy we touch nearly on that department of knowledge which in modern nomenclature is distinguished from science under the name of philosophy. Philosophy is something very different from science in the restricted modern sense. It is a word which has always been used to designate the methodical search after the highest truths which interest humanity. Before the sciences had a distinct existence, philosophy contained the germs of them in its bosom. It has been not inaptly described as the science of the sciences, inasmuch as the generalization and conclusions of the individual sciences furnish data on which it founds. It is not a structure built directly on observation of individual phenomena; such observation is not the instrument by which philosophy in the restricted sense is advanced. The object of philosophy is to penetrate to the unseen; to discover, as far as may be possible, the sources of all things, both of being and of good and evil; and this end is sought by processes of further generalization than those attempted by the various

* Reprinted from the *Medical Times and Gazette*, Dec. 5.

sciences. All the sciences are useful for philosophic purposes; none of them to be despised; and I grant it is sufficiently plain that it is a most unsafe thing for any man to speculate on the nature of matter who has taken no trouble to inform himself as to what is known of the phenomena of the thing about which he talks. But it is not only the external world which has to be taken into consideration by the philosopher; the media through which the mind has cognizance of an external world, and the nature of that mind which takes cognizance must also be made the subject of investigation. Therefore, psychology takes its place as one of the most important bases from which the philosophic structure must spring; and you will perceive that no man has a right to put himself forward as an authority on questions of philosophy, on the mere strength of having spent his life in physical science. In the first place, physical science does not afford the whole material on which a philosophy can be founded; and in the second, a man who is an acute observer of the phenomena which he can appreciate by the aid of his senses may do most important work in the physical sciences, although he may be deficient in the logical power required for the higher generalizations—not to mention that he may be defective in those elements of judgment which are necessary for common sense. Take the question of the origin of man, or his position in the world. The studies of the biologist enable him to speak of man's zoological relations; and, indeed, none but biologists are in a position to express an opinion on that subject. The biologist, however, is right when he states that for any other than mere zoological relations he has no instrument at his disposal in his particular department of knowledge; and he is wrong, egregiously and culpably wrong, if, on that account, he pawns upon a credulous public a statement or even insinuation as based on the sure methods of science, that man has none but zoological relations, or that any other are to be ignored as beyond the power of investigation.

I have spoken of philosophy only as it is founded on science. You will probably many of you ask in your hearts, if I put Christianity or revelation overboard. To that I answer, certainly not. Christianity deals also with the highest questions which interest humanity; but in a totally different way. And, indeed, therein is its advantage; for philosophy is for the few, the very few, and Christianity for all. Philosophy and religion do not clash, but they are independent one of the other. I do not enter into religious matters in detail, because it is not my province, and because the principle on which these colleges are founded is, that religion shall be respected, and the tenets of no man interfered with, but that, inasmuch as all sections of the community are not of one way of thinking, whatever pertains to religion shall be left entirely for the various clergy to supply to their own adherents. Of this, however, we may be certain, that truth is one and harmonious in its parts. Parts far asunder and separate one from the other may, indeed, sometimes appear irreconcilable, till the gap which separates them is filled; but they shall surely be seen to agree in the long run. Therefore we can never do wrong, with due reverence and complete self-forgetfulness, unblenchingly to face and inquire into any aspect of truth which is presented to us.

I have said that the physical sciences are insufficient to serve unaided as a foundation for a philosophy, and there are some branches of philosophy—as, for example, ethics—to which they stand in little, if any, immediate relation; but there is one question on which they have an indubitable bearing—namely, as to whether the universe is to be traced into an intelligent source. One hears a good deal of talk about the materialistic tendencies of the age, and of physical science, and also of medical studies (which an ungrateful public has always been suspicious of); and I am not going to deny that there is foundation for talk of that kind; but I take leave to make just two statements on that subject. In the first place, if you will keep living physicists out of consideration, as it might be an invidious task to settle their claim to niches in the temple of fame, I think you will find that scepticism as to the intelligent source of the universe has not been fostered by the intellects of the highest order. Very sure I am that you will easily call to mind scientific authorities of the very highest type—men who were not mere observers of phenomena, but of the profoundest and clearest judgment that the world has seen—of whom that remark is true; and this I say, not because I would have you allow that or any other important doctrine to rest on the dictum of scientific men, however great, but because I would have you notice that the highest mountains rise above the mists, although perhaps they may sometimes be particularly cold; and because I frankly admit that there is quite sufficient shallow materialism abroad to tempt the young student to imagine that anything else is contrary to what is grandiloquently called "the precise methods of modern investigation." By all means be precise; but commence by pinning physical methods precisely to their proper place. In the second place, I have no hesitation in stating, as I have hinted already, that the study of anatomy, especially comparative anatomy, affords the most incontestable proofs of the existence of Deity, and that to espouse a contrary belief is to occupy a position from which it is impossible to appreciate morphology. If I find in a series of animal forms, arranged according to their places in an ascending scale, that the structures exhibit the evolution of a harmonious plan to which adaptation to external circumstances plays a mere subordinate part, then I must at once acknowledge an intelligent source—and that is just what I venture to say that no unprejudiced student of comparative anatomy can fail to see. Even in mere human anatomy what we call serial homology points to the same thing. Those of you who have studied the skeleton are familiar with the correspondences of one segment with another, and more particularly with the accurate correspondence of the bones of the hand and the foot; and you will judge rightly that nothing but a purely morphological unity of design will account for the detailed correspondences in two structures placed in the same organism and fitted for widely different purposes.

The propositions which I have ventured to lay down, you will perceive, are principally two; first, that the physical sciences do not afford sufficient material by themselves for the just consideration of the source of being, nor are its votaries necessarily accustomed to the methods which should be employed in contemplating that question; and secondly, that the material which is furnished by the physical sciences and more particularly by the study of organisation, affords important evidence of the existence of an intelligent source. That second proposition I have laid before you merely as an assertion, but my object is simply to direct your attention to the subject, that, as you progress in your anatomical studies, you may judge for yourselves if the assertion is true.

IS LICORICE JUICE FERMENTABLE?*

There exists in the root of licorice and some other plants a sugar-like substance which comes into commerce as an extract, or inspissated juice. The active principle of this is a yellowish-white powder with a pleasant bitter, sweet taste, and is called *glycyrrhizin*. Although it has been popularly supposed that this juice was not infrequently used by brewers, this supposition was met by scientific men with the assertion that this substance was not capable of undergoing fermentation, and hence could be of no use to the brewer. Dr. Griessmayer has instituted some experiments, and his results seem to contradict the latter assertion. On dissolving glycyrrhizin in cold water, in which it is not very soluble, a yellow solution is obtained, which has a brown colour by reflected light, and possesses a peculiar odour like that of smoking tobacco.

* *Journal of Applied Chemistry.*

On heating the solution a fine yellow foam rises, which soon subsides on boiling. The vapours given off have a pleasant aromatic odour.

Glycyrrhizin is a glucoside, a body which, on warming with a dilute acid, splits up into glycyrretin and sugar. If, then, any free acid, like phosphoric or succinic, were present in the root, it would serve to produce this change during the mashing, or on boiling the hops. But even boiling alone seems to effect this change; for after a solution has been boiled for some time without anything being added, it is capable of reducing the alkaline copper solution. A cold saturated solution of course will not do this, not even on heating it with the tartrate of copper, and hence the error arose of supposing that glycyrrhizin would not reduce the copper solution at the boiling point. The cause of this difference of behaviour is evidently due to the alkalinity of the copper solution, which prevents the glucoside from splitting up.

In order to decide the question whether the sugar liberated by previous boiling was really capable of undergoing fermentation, 400 c.c. of a solution of licorice was first boiled, then cooled to the temperature of the room, 87°F., and 0·5 gram of yeast added. In about six hours the evolution of carbonic acid was observed, and in three days the fermentation was over. The presence of alcohol was proven both by distillation and by Liebig's test. Toward the end of the fermentation a very offensive odour was given off, and this of course went over to the distillate. The fermented liquor contained no bacteria or vibriones, but perfectly healthy *saccharomyces cerevisiæ*. It is natural to suppose that the vile taste and smell of certain beers arise from the addition of licorice.

THE ACTION OF SOLIDS AND OF FRICTION IN LIBERATING GAS FROM SOLUTION.*

BY CHARLES TOMLINSON, F.R.S.

In the *Philosophical Magazine* for April, 1873, I stated that chemically clean solid bodies, in their behaviour towards gaseous solutions, admit of being arranged into four classes or groups. The first group includes glass, and all vitrified and siliceous surfaces, and the denser metals, including mercury. The gaseous solution, whether supersaturated or not, adheres to the chemically clean surfaces of these bodies in the most perfect manner, so that there is no separation of gas.

The second group includes oils, both fixed and volatile; fatty bodies, whether acid or neutral, various kinds of wax, resin and gum-resin, camphor, spermaceti, and similar bodies, not soluble in water. The surfaces of such bodies, though chemically clean, liberate gases from their aqueous solutions; and they do so the more efficiently, in proportion as their surfaces are less liable to be wetted by the water of the solution. In other words, the gas adheres to such surfaces with greater force than the water.

When it is said that a body in Class I., not chemically clean, liberates gas from solution, it is contaminated more or less with one of the substances in Class II.

The third class consists of porous solids, which are eminently active in liberating gas from solution. This class includes woods of all kinds, hard and soft, and the charcoals made from them; also coal, coke, anthracite, jet, plumbago, roll sulphur, pumice, meerschaum, bone, ivory, chalk, lime, indigo, and the less dense metals, such as aluminium and magnesium; and lamillar metals, such as antimony; and crystalline metals, such as bismuth, which contain a good deal of occluded gas. The strong adhesion between the gases and the pores of bodies in this class may be strikingly exhibited by placing one of them in soda-water, when it becomes apparently saturated with the gas, whilst more gas seeking to precipitate itself upon the innumerable surfaces already occupied gives rise to the appearance of a stream of gas constantly ascending from the porous surface until the liquid seems to be exhausted; but the action may be renewed by reducing the pressure or raising the temperature. In the latter case, when the gas is expelled and the liquid is at or near its boiling-point, it is constituted exactly like the soda-water, which may be called an aqueous supersaturated solution of CO_2, while the other may be termed an aqueous supersaturated solution of steam.* A strip of aluminium ($1\frac{3}{4}$ inch by $\frac{3}{4}$ inch) cleaned by being rubbed between two corks in the strongest oil of vitriol, and rinsing in water, was active in disengaging gas from soda-water; and when taken out and put into water, over a spirit-lamp, it liberated such copious streams of vapour, when the water boiled, as to be supported vertically on one of its long edges, while innumerable bubbles issued from both sides, and continued to do so for about a minute after the lamp had been removed. When taken out and cooled in cold water and again transferred to soda-water, it was as active as before in occluding and liberating gas.

The fourth class of bodies are those which are soluble in water, and act by lessening the adhesion between the gas and the water, as when powdered white sugar is put into a glass of sparkling Moselle wine. A piece of gamboge in soda-water is also a good example of this class, while bodies so little soluble as phosphorus and iodine belong to it.

The results obtained with all four classes of solids in their action on soda-water may, with proper precautions, be obtained with aqueous solutions of ammonia, of hydrochloric acid, of chlorine, and of nitrous oxide, and also with liquids at or near their boiling-points.

Next, as to the effect of friction. It has long been known to chemists that certain saline solutions, which show no disposition to deposit crystals, may be started into crystalline action by rubbing the inside of the vessel below the level of the solution with a glass rod. This effect is produced, although every part of the arrangement be chemically clean; and it has not, so far as I know, been explained. It is the same with a gaseous or vaporous solution. Soda-water, in a chemically clean test-glass, in which not a bubble of gas is visible, will display a line of bubbles along the path described with friction by a clean glass, metal, or other rod, against the inside of the glass below the level of the liquid. So also, if a glass rod be rubbed against the side of a vessel containing a liquid (such as spirits of wine, or a saline solution such as one of common salt) at or near the boiling-point after the source of heat has been removed, bubbles of vapour may be liberated so abundantly that the liquid may be made not only to boil, but to boil over.

A gentle rubbing sometimes fails to convert a friction line into a bubble line, whereas harder rubbing and a quicker motion produce the effect. And in general hard bodies are more efficacious in producing the result than soft ones. It is not necessary that the friction produce an actual scratching of the surface; nor does the track of a bubble line remain more sensitive than other parts in liberating gas after the first display is over. The more highly supersaturated or superheated the solution the more sensitive the surface appears to be, and the smaller the amount of friction required. Beer gently warmed produces foam by rubbing the side of the vessel. Or if, instead of rubbing the side of the vessel, two solids such as copper and steel be introduced into the liquid and rubbed against each other, bubbles are produced.

An explanation of these interesting facts, offered by Professor Schrötter (*loc. cit.*), is to the effect that the friction immediately produces a change of mechanical action into latent heat or work.

* From the *Philosophical Magazine and Journal of Science* for November.

* This definition is given in a paper read before the Royal Society, January 21, 1869 ('Proc. Roy. Soc.' vol. xvii., p. 240), "On the Action of Solid Nuclei in liberating Vapour from Boiling Liquids." I may state that Professor Schrötter (Pogg. *Ann.* vol. cxxxvii.) accepts this definition.

Some of my scientific friends to whom I have showed these effects, endeavour to explain them by supposing that the friction produces heat, or electricity, or some molecular change on the surface of the vessel.

My explanation is derived from a more vulgar source. From the shelter of an archway during a heavy fall of rain I have watched the extemporized puddles before me, and admired the large bubbles of air which frequently follow those drops which plunge into the miniature lake with something like decision of character. Old Mariotte was interested in the same phenomenon. He says, "Each drop of rain, in falling from the height of the cloud, drags with it two or three times as much air as its own size, as may be shown by letting a little ball of lead fall into a bucket of water; for as soon as it touches the bottom two or three bubbles of air rise, each as large as itself, which can only proceed from air which follows it to the bottom of the vessel." He then refers to the *trompe*, in which air is dragged down by water*.

Mariotte's experiment, differently arranged, forms a good illustration for a class. Over a tall glass cylinder of water is suspended a funnel with its beak from 20 to 25 inches above the axis of the water-jar. A shot put into the funnel will thus be delivered neatly and properly to the water, and as soon as it strikes the bottom a number of bubbles of air are liberated, some say twenty times (Mr. Rodwell informs me thirteen times) the volume of the shot†. The old idea (still retained in some modern books) was that the air thus liberated was air adhering to the shot; to disprove which I oiled some shot and dropped them in, with the same result.

The more rational explanation is that the shot, in plunging into the water, displaces a quantity of that fluid in the form of a well or cylindrical shaft, to which the shot forms the lower boundary, and into which air, as the more mobile body, rushes before the water has time to close over it; and as the shot is still pursuing its journey, it makes a path which the cylinder of air continues to follow until both are arrested at the bottom of the vessel, where they are disposed of according to their respective densities and that of the surrounding medium.

Now to apply this to the liberation of gas from soda-water, etc., by the friction of a hard body against the side of the vessel. The glass rod or the steel knitting-needle, on being pressed against the side of the glass, displaces a certain small quantity of the liquid, and on moving the solid, with friction, against the side successive quantities of liquid are thus displaced. A certain time, however short, must elapse before the water can fairly close in upon the moving points of the line thus traced; but however quick the water may be in filling up the void, the gas is quicker, and hence a friction line becomes a line of bubbles.

The same explanation applies to other gaseous solutions, to solutions of vapour, such as spirits of wine at or near its boiling-point, and also to certain saline solutions. The gas, or the vapour, or the salt, fills up the spaces in the friction line more quickly than the liquid part of the solution can do; and thus we have a line of gas, or of vapour-bubbles, or a line of minute crystals.

Highgate, N., October, 1874.

ANALYSTS AND THE ADULTERATION ACT.

At the recent general meeting of the Newcastle-upon-Tyne Chemical Society, an introductory Address was delivered by the President, Mr. John Pattinson, in which, after recounting the work done by the Society during the previous session, he referred to the position of chemists in relation to the Adulteration Act, in the following terms:—

"The working of the Adulteration of Food Act of 1872 has for some time past attracted considerable public attention, and there can be no doubt that great injury and injustice has been done to many honest traders by the way in which its provisions have been carried out. This injury to the tradesman has also, I regret to say, been in too many instances the result of incompetency on the part of the analyst, and sometimes even due to a want of judgment, and of what may be termed commercial common sense. Respectable tradesmen have had to submit to the disgrace of being convicted and fined for selling for mustard what every purchaser knows as mustard, viz., a mixture of flour and ground mustard seed; for selling, under what is merely a trade name—effervescing citrate of magnesia—a substance which was well known did not contain citrate of magnesia, and the purchaser of which would have complained bitterly if it *had* contained any; for selling tea containing a few grains of probably accidentally adhering sand, or coloured on the surface with an infinitesimal amount of harmless colouring matter, placed there to please the eye of the customer, but with no intention of fraud. Surely the analysts and authorities instigating these proceedings believe there is something in a name, and are determined to enforce the exact use of language in a way which it is difficult to resist. Then, again, the conflicting evidence given by analysts in many cases, and the too high standards of purity by which the articles of consumption were frequently judged, showed that the necessary amount of knowledge to do their work properly was wanting in some of the persons who had received appointments under the Act. Our secretary, Professor Marreco, drew attention to this subject at one of our last year's meetings, and strongly urged that in the interest alike of the buyer, the seller, and the profession, the appointment of public analyst should only be given to those persons who hold a certificate from some recognised and competent body of examiners, giving some guarantee that the holder thereof possesses the requisite medical, chemical, and microscopical knowledge. Since then a Select Committee of the House of Commons have inquired into the operation of the Act, and in their report they make the same suggestion, and further suggest, what does not meet with such general approval, that the examining body be the authorities at the School of Chemistry at South Kensington. After all, the number of mistakes made by the analysts is fewer than might have been expected when all the circumstances are taken into consideration. When the Act was first passed, but very little attention had been given to this branch of analytical chemistry, and the methods of analysis of many substances were very crude and uncertain. The limits of variation in the composition of pure articles of consumption were in many cases unknown. It is worthy of remark that the evidence taken by the Select Committee of the House of Commons shows that the greatest diversity of opinion prevailed even amongst those chemists who stand highest as food analysts. Dr. Voelcker and Dr. Tidy's standards for pure milk were very different from that of Mr. Wanklyn; and Dr. Voelcker and Mr. Wanklyn asserted, very positively, that the presence of foreign fat in butter could not be detected, whilst Dr. Hassall stated as positively that it could. Until our knowledge of this branch of chemical analysis is considerably increased, we are therefore likely to have cases in which differences of opinion exist, and doubtless occasionally different results of analysis obtained. The Select Committee, in pointing out that in some cases magistrates have declined to allow any other analysis to be taken as evidence than that of the analyst appointed to act for the district, very properly say they think that evidence from well-established analysts should be allowed to be produced for the defence, and suggest that, when cases of dispute arise between the chemical authorities, there should be some court of appeal to settle the disputed points. They also suggest, in the absence of further information as to any better appeal, that where the analysis of the chemist of the local authority is challenged, the sample in dispute shall be analysed at the laboratory at Somerset House, and the decision arrived at there be regarded as final. At an important meeting of public analysts held in London in August last, to take the report of the Select Committee into consideration, this proposed appeal to the Somerset House laboratory was most strongly objected to, and a resolution was passed to the effect that no referee's decision in a disputed case should be accepted as final unless it be given on oath and tested by cross-examination. The meeting further objected to the suggestion that public analysts should be called upon to pass an examination at the College of Chemistry at South Kensington, or elsewhere, on the ground that such examination would lead to the exclusion of chemists of experience, and to the appointments falling into the hands of young and inexperienced men. There is the further objection that undue preference would thus be given to one teaching institution to the detriment of others equally efficient. Perhaps the best and most practicable suggestion was that first made, I believe, by Mr. Allen, of Sheffield, that in order to secure a board of referees in which the analysts and the public would have confidence, it should be elected by the analysts themselves. They are best able to know the fitness of the men to occupy this position, and they would take care to select men of undisputed standing and of known special experience. The editor of the *Chemical News*, I believe, was the first to make the excellent suggestion that the board of examiners, to decide the fitness of candidates for the office of public analysts, should also be appointed by the public analysts themselves. A board of referees and examiners elected in this manner would secure the confidence of food analysts and the public generally, and it would be free from the objection of unfair preference for one teaching institution to the disadvantage of others.

"From the evidence taken before the Select Committee there is no doubt that on the whole the effect of the Act has been productive of good. A considerable check has been given to the adulteration of many articles of consumption, such as milk, tea, bread, flour, etc., and a wholesome deterrent influence has been exercised, the extent of which cannot be measured by the number of convictions which have taken place. The public mind has been set at rest regarding the sensational stories which have gone the round of the newspapers as to butter made from Thames mud, milk made from sheep's brains, iron filings in tea, etc., etc. The usefulness of the Act will doubtless be very much increased by the amendments it will receive during the next session. Amongst the amendments suggested in the report, I am glad to see the one that the sale of goods to inspectors should be made compulsory on the money value of the goods being tendered. I have, myself, now great difficulty in getting hold of samples of milk which are supposed to be adulterated. The milk dealers know the inspectors, and, of course, assert they have no milk to spare when he applies for a sample. Under the present Act there is no power to compel the sale.

"The shortcomings of food analysts will probably soon be removed to a great extent. A vast amount of valuable information on the analysis of food is being collected and disseminated. Already several handbooks have been published, and a number of articles have appeared in our scientific journals, on the best methods of examining various articles of consumption, so that, in a short time, we may hope to hear less of the unseemly conflicts of evidence and of unjust convictions arising from errors of analysis. Meanwhile, until such knowledge is obtained, chemists should strive to prevent their zeal from outrunning their discretion. In all doubtful cases it is always wise to follow the practice of our English law, and give the prisoner the benefit of the doubt.

"At the meeting above referred to, the public analysts formed themselves into a society with the proposed title of the 'Association of Public Analysts,' for the purpose of mutual assistance and co-operation. This organisation will afford the means of carrying out the suggestions relating to the appointment of a board of examiners and referees, should the legislature see fit to adopt them. One of the most important uses of this association is, however, the opportunity which it gives of its members making known to each other the results of their various investigations, and of having the proposed methods of analysis discussed, so that accurate and uniform methods may be readily arrived at. It is very much to be regretted that the association proposes to elect its members from food analysts only. Its usefulness would be immensely increased by widening its scope so as to include analytical chemists of all classes. The desirability of having a competent tribunal to whom to appeal when conflicting analyses of various commercial products are obtained, is often felt both by commercial men and analytical chemists, and it appears to me that a board selected from an organized association, which should embrace analytical chemists of all classes, is the proper tribunal to appeal to in such cases. It is to be hoped that the association of food analysts just formed will yet see its way to somewhat alter its name and scope, and thus materially extend its usefulness both to the trading public and the profession at large.

"So pressing had the question become of the formation of a court of appeal to decide disputes in commercial analysis, that our Society received a communication in May last from the chemical section of the Glasgow Philosophical Society asking us to join them in a memorial to the chemical section of the British Association, requesting that a committee of that section should be appointed to inquire into the subject of commercial analysis, and especially with reference to the analysis of potash salts and superphosphates. A special meeting of our Society was called in that month, and the matter was discussed. Many of our members were of opinion that the processes of analysis of many of the substances in which we on the Tyne are more immediately concerned, such as soda, sulphur, manganese, and copper, call equally urgently for investigation, and many instances were given of great discrepancies in the results of analysis of the same substances given by various chemists, involving, of course, the loss of large sums of money either to the buyer or the seller. It is, moreover, somewhat compromising to our analytical and commercial morality to find out, for instance, that large profits have been made by buying soda ash by one chemist's test in one district and selling by that of another chemist in another district, whilst at the same time both chemists professed to test by the same method; yet this is known to have occurred. Surely there is here gross carelessness, or worse, on one side or the other. A resolution was ultimately passed at the meeting expressing the opinion that a sub-committee of section B of the British Association should be appointed to inquire into and report upon the processes employed in commercial analyses, and more especially the analysis of copper, soda, potash, sulphur, and superphosphates and other manures. The British Association, at their Belfast meeting took the matter into consideration, and have appointed a committee with a grant of ten pounds to inquire into and report upon the methods at present used in the analysis of potash salts and superphosphates; so that we may hope to have a report on the matter at the next meeting of the British Association."

THE WILD VANILLA PLANT.*

By vanilla plant we do not refer to the orchid which furnishes vanilla, but to a hardy North American plant, *Liatris odoratissima*, which, on account of a similarity of odour, has received that name. Most of the species of liatris, or button-snakeroot, have a tuber-like root, and long straight stems, upon which the numerous flower-heads are crowded in a close spike. In *L. odoratissima*, the root-leaves are from 8 to 12 inches long by 2 or 3 broad; those of the stem very small. The stem divides above into a broad branching panicle of purple flowers, which make

* From *The Garden*.

the plant an attractive one. A correspondent of the *American Agriculturist* has furnished the following account of the plant:—"The wild vanilla, or, as it is commonly called, hound's tongue, or deer tongue, grows abundantly on the edges of what are called 'bays,' *i.e.*, low places in the pine woods, which are partially covered with water and overgrown with bays (a species of magnolia), or on low swampy pine woods in east and south Florida, and in portions of lower Georgia. The fresh leaf has, when crushed, a greenish disagreeable odour, but when pulled from the plant and dried in the shade for a day or so, it becomes highly fragrant, having a smell resembling vanilla or tonka bean, and similar to the sweet-scented vernal grass, but much stronger. This odour is developed by some chemical change made in the leaf during the process of drying, whereby a peculiar principle known as coumarin is formed. Coumarin is found abundantly in the tonka bean of commerce, but so abundant is it in the *Liatris*, that it is often found in large quantities on the upper portions of a mass of the semi-dried leaves. It is readily sublimed by a low degree of heat (150°), and the heat generated in these masses or bundles is sufficient to sublimate it on the upper or cooler layer. When found in this way, coumarin is composed of snow-white needle-shaped crystals, exceedingly fragrant—a leaf of the *Liatris* often being covered on its under side, and looking as though it had been out all night in cold, frosty weather. The dried leaves furnish an article of commerce, and one that is steadily growing in importance. It is gathered all through east and south Florida, principally on the St. John's River and its tributaries, and sold to the country store-keepers in exchange for goods; by these store-keepers it is sent to the balers and packers, by whom it is sent to New York for home use and exportation. Pilatka, on the St. John's River, is the head-quarters in this trade. One may often see 75 or 100 bales, of 200 lbs. each, lying on the wharves, awaiting shipment—one dealer at this place having an order to fill of 150,000 lbs. Adults can gather from 150 to 400 lbs. of the green leaves in a day; active boys and girls nearly as much. The green leaves are taken home and dried in the shade, and lose about 80 or 85 per cent.; they are, when dried, sold at the country stores, for from 3 to 6 cents per lb., yielding quite a good return for the labour. The packer bales and ships, and realizes from 8 to 12½ cents per lb. The dried leaves are used to give a flavour to cigars, snuff, and smoking tobacco. For cigars, it is sufficient to place the leaves and the cigars in alternate layers in a box, and allow the whole to remain together for several days; for snuff, the leaves are dried, ground, and mixed; it is granulated, or shredded up, and mixed with smoking tobacco. A small quantity is sufficient to flavour a large mass of tobacco. The odour is given off much more intensely on a damp day than on a dry one. Although large quantities of these leaves are consumed in our home factories, a much larger quantity is shipped to Germany and France direct, where it is rapidly growing in favour. It is quite probable that it will soon be an article used extensively in perfumery; and as it is known to keep 'the wicked moth away,' it will be in great demand for the purpose in the stead of the strong-smelling camphor and tobacco stems."

COPAL.*

The following extract is taken from an article in the *Geographical Magazine* relating to the products of Eastern and Tropical Africa:—

The *Msandarusi*, or copal tree (*Trachylobium sp.*), according to Captain Elton, is largely scattered over an extensive tract of country, in the Mrima, or coast region. This tract lies along both banks of the Lufiji, and extends from the mountains to the sea, a belt from 30 to 35 miles wide. Throughout these limits immense quantities of the semi-fossil are dug up by the natives, and this constitutes the most lucrative commerce of the Indian settlers at the small trading ports. Further south, beyond the Lufiji, there is a break in the supply, attributed by Captain Elton to the surrounding slave traffic, which rapidly drives legitimate commerce out of its course, but also affected by the increased difficulties of communication caused by the marshy swamps which here fringe the coast more deeply than above the Lufiji. Beyond Kliwa copal again appears, and is largely bought up, in tranquil times, at the numerous trading stations which dot the seaboard down to the Rovuma River.

The copal tree is described by Burton as a large tree, the towering bole of which has formed canoes 60 feet long. The bark is smooth, the trunk of a yellowish white tinge, rendering the tree conspicuous amid the dark African jungle growths, and is dotted with exudations of raw gum, which is also found scattered in bits about the base. The forests, called *kiregesi*, contain many *msandarusi*, or copal trees, and between them, in the broad transverse glades which always intersect African woodlands, some of the finest fossil gum is dug. This never reaches the trader, however, without a large admixture of the copal from the neighbouring trees, and the contents of the digger's basket are made up with wet sand and small stones, in order to give it a little extra weight. The chief centre of supply is the Kwale district, where there are eleven stations for carrying on the copal trade. In the early morning strings of natives are seen on the paths, each party led by a few men, armed with old muskets and bows and arrows, and consisting of women and lads, carrying copal baskets. Except during the very dry season, these arrivals take place daily, but there is no organized system of working. The Indian traders do not venture to send out parties of their own, for each village and each working is represented by a head man, and the natives are only too ready to unite against the slightest encroachments on their monopoly. The "trade union" system is here represented in its strongest form.

Below four feet no gum is found worth taking, and very few diggers go beyond three feet in search of it. The trade appears to be surrounded by many difficulties. The Indian trader, on the Mrima coast, has many extortions to contend against, and heavy duties to pay, besides the continual haggling with the natives, competition with his neighbours, and a perpetual round of coast fevers. The local village headman extracts a ground rent from him; and he has to pay an arbitrary percentage on his profits and twenty out of every hundred *frasilahs* of copals shipped as an export duty. The cost is from 3 to 5¼ dols. per *frasilah* of copal, varying according to the season of the year, and at Zanzibar the merchants buy at from 7 to 8 dols. Yet, in spite of all difficulties, the trade prospers; and Captain Elton is of opinion that the inexhaustible supply of copal, under a settled rule and with systematic working, would furnish the means of supporting a far larger community than that which is now sparsely scattered along the coast.

In old days the trees would appear to have lined the shores, but the extent of the ancient forests can now only be estimated by the area of the present workings, and by the positions of the existing *msandarusi* which are found away towards the foot of the low hills bordering the Mrima, and on all the terraced lands sloping down from the ridges to the present sea-beach. *Msandarusi* is the true or ripe copal, the produce of vast extinct forests, and buried at depths beyond atmospheric influence. The raw or tree copal is called *chakazi*. It is little valued in European markets, but is exported to Bombay and China. A most interesting account of copal and the copal trade is given by Captain Burton in his 'Lake Regions.'*

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W.*

Envelopes indorsed "Pharm. Journ."

EARLY CLOSING.

THE receipt of the Report of the Early Closing Association furnishes an opportunity for reverting to a subject in relation to which, up to the present time, pharmacists have made nearly the least advance of any class of the trading community. If this be thought to be an exaggerated statement, it will find sufficient justification in the fact that when the Early Closing Society attempts to show by force of contrast the large amount of good accomplished by its efforts, it draws a picture of "thirty years ago" which is only too faithful a picture of pharmacy in 1874. "At the outset of the Early Closing Movement, *ten* o'clock was the prevailing hour for the closing of shops in the *retail* trade of London; the time of the actual release of the assistants was still later." To-day it can be reported that by silk mercers, linendrapers, hosiers, and other retail traders, the hours of 8 in summer and 7 in winter have been largely adopted and are making rapid progress. But what about pharmacists? Unfortunately, although there are many who are acting as pioneers, by closing their establishments an hour or two earlier, the description of thirty years ago is still applicable to a large majority.

In this report of the Early Closing Association it is properly pointed out that the most effectual method in bringing about earlier closing has been to arrest public attention and to bring public opinion to bear upon late closing. In certain callings sympathy has been evoked for employers and employed who formerly suffered from long and late hours, and now it has become unfashionable and unpopular to close late. Various remedies have been advocated by persons who have lost patience with the necessarily slow progress of the voluntary movement, but the Board of Management has, after careful consideration, decided to persevere unhesitatingly in the old and tried policy of attempting to eradicate the evil by persuasion and argument only. Notwithstanding the hindrance caused by the perversity of isolated employers who refuse to join the majority, this policy has, on the whole, been successful, whilst it is free from all the probably insurmountable difficulties that would attend compulsory legislation.

We are glad to have such a valuable ratification of the course we ventured to take in respect to Sir JOHN LUBBOCK'S Shop Hours' Regulation Bill. Some of our correspondents have thought differently, and have at different times expressed the opinion that Sir JOHN'S attempt at compulsory legislation ought to have had the support instead of the opposition of the Council of the Pharmaceutical Society. But we agree with the Board of Management of the Early Closing Association that however desirable it may be that shops should be closed at 8 o'clock in the evening, there is not the slightest chance, unless a decided change comes over the British Legislature, of such a law being passed for the purpose. Indeed, were the law passed, the evasions that would result from the admittedly necessary exemptions would, as we pointed out at the time of the introduction of the Bill, render it ridiculous and unworkable.

This conclusion has not been arrived at without consideration. In March last a meeting of employers convened by Mr. SAMUEL MORLEY, passed a resolution in favour of an uniform compulsory closing of shops at 8 P.M., and appealed to the Early Closing Association to co-operate in promoting such a measure. The result was the issue of a statement in which the matured opinion of the executive of the Early Closing Association was represented as being distinctly adverse to compulsory legislation, and ample reason was given in support of the opinion. We regret, however, to notice that there appears to be a disposition to coquet with "permissive legislation" on the same subject, although it is acknowledged that the result would probably be very limited and confined to small communities, where the pressure of long hours and overwork in connection with trade is but little known.

In conclusion, we would urge every one of our readers to make sure that he is doing his utmost by example and by influencing public opinion, rather than look to the Parliamentary Jupiter to get the wheel out of the rut. We suggest that the Press and the Pulpit both might be found more extensively available were proper applications made. If this were done there might be some prospect of pharmacy being included in the Early Closing Society's next report amongst callings which have equally valid excuses for late hours, but are turning their backs upon the practice.

CHINESE PHARMACY IN SAN FRANCISCO.

As we descend in the social scale, we find the quack, the astrologer, and the conjuror in ever greater request, more particularly in those countries where there is a constant influx of the labouring classes. California, and its capital San Francisco, fulfil nearly every condition under which the "irregular practitioners" above-mentioned succeed; and of these the greater proportion are Chinamen. Constantly advertising in the San Francisco press, or flaunting their diplomas (generally bogus ones) in their shop windows, the Chinese doctors drive a "roaring trade" among the floating or resident population of the city. There are eighteen of them in regular, or rather "irregular" practice, their names and professions paraded in Chinese and English characters at every turning. At the commencement of practice they accept the humblest honorarium; and if they assist at the death of one of their compatriots they invariably register him as having "died from unknown causes." The most prominent of them is the anglicised Chinaman, Dr. LI-PO-TAI, who is located in a showy suite of apartments, which are daily thronged with patients, principally of the softer sex and of European complexion, for whose benefit some five or six pupils of the doctor are seen busily preparing the decoctions charged with life or death. The doctor first manipulates his patient's pulse, then the joints of the arms, after which he is prepared to point out the seat of the malady and the appropriate cure. The quality of the medicine, as well as its quantity, is determined by the purse and the patience of the client, who is expected to state his preference for a cure which shall be short and sharp, or for one which shall be prolonged and painless. The medicines are nearly all of vegetable origin: gentian, rhubarb, myrtle, and camphor are the chief, to which are added some nondescript Chinese roots, rinds, leaves, and seeds, administered in homœopathic doses, and generally in the form of pills and decoctions. Ignorance of chemistry keeps the Chinese doctor clear of mineral acids and re-agents, mercury being about the only inorganic element used, and that in very few preparations.

The principle of Chinese therapeutics seems to be the effecting of cure, not by sympathetic or homogeneous, but by contrary means. For syncope or weakness they prescribe the blood-extract of the tiger; and so on till almost every animal is laid under contribution for an essence which is also an antidote. The blood and the liver are the sources from which these animal-specifics are mainly drawn. "Eye of newt, and toe of frog" are also in high esteem with the Chinese practitioner, whose stock-in-trade is chiefly imported from his native country, and comprises snakes, lizards, toads, bugs and spiders, all in the dried state; along with claws, ears, tongues, teeth, hearts and livers. These latter are taken from animals of every possible kind, and are found in immense quantities in the Chinese medicine stores of San Francisco.

The Chinese doctors have little or no knowledge of anatomy. They take the lungs to be the seat of the voice; the stomach, the residence of the emotions; the liver, that of the soul; and the spleen, that of the reason; while this last, in conjunction with the heart, engenders thought. The gall begets courage, and on that account takes rank with the most potent medicaments. But the materia medica includes other agencies. To conquer a malady the Chinese physician must have under control the evil spirits who trouble the breath or generate bad humours. Indeed, without this control, the physician does not pretend to possess the proper remedy or to guarantee a favourable result. Significantly enough, the most "positive" department of the healing art, surgery, is a *terra incognita* to the Chinese practitioners—at least, in California. Kneading, rolling, and stretching are the remedies employed for fractures, while poultices of cat's liver (cat-aplasms?) and of cocks' entrails, are favourite applications. Decayed teeth are punched out with the familiar forceps. Strange to add, these odd people must possess a sovereign remedy for small-pox. During the prevalence of that epidemic, not a single Chinaman fell a victim to it, though none of them had been vaccinated.

Chinese medicine, indeed, is as inscrutable as Chinese metaphysics; and is likely to remain so. Its practitioners have the greatest contempt for Western science, as they have the grossest ignorance of it. In this respect they stand in marked and melancholy contrast to their neighbours, the Japanese, who are courting every opportunity of educating themselves according to the standards of the West. It was but the other day that the son of the MIKADO's body-physician, SATSO SUMA, by name, graduated as Doctor in Medicine at Berlin, after a severe examination, and defended his thesis with fluency and effect in the German language, which he had mastered in a few months Such is by no means an isolated example of Japanese enterprise in the matter of education, and it requires no conjuror—certainly not a Chinese one!—to tell us which of the two nations gives better promise of ultimate superiority.

A NEW CHEMISTS' ASSOCIATION AT WOLVERHAMPTON.

WE are glad to learn from a report which has been kindly forwarded to us by a correspondent, that it has been resolved by the Chemists and Druggists of Wolverhampton and District to form a local Association, which shall have for one of its principal objects the provision of lectures, classes, museum, library, etc., for instruction in pharmacy and the allied sciences.

We hear that classes are already in the course of formation, and that the first meeting of the Society will take place on Tuesday, January 5th, 1875. The Honorary Secretaries (Mr. W. Y. BREVITT, Darlington Street, Wolverhampton, and Mr. F. J. BARRETT, the General Hospital, Wolverhampton) will be glad to receive for exhibition any articles of interest, or donations of books and scientific periodicals for the library and reading room, and specimens of chemicals and drugs for the contemplated museum.

WE are informed that one of five gentlemen who have recently been added to the commission of the peace for the Borough of Hull, is Mr. Alderman JOHN LOVE SEATON, whose name occurs on the Register of Pharmaceutical Chemists.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Fourth General Meeting of the Liverpool Chemists' Association was held at the Royal Institution, on Thursday, December 3rd. The President, Mr. A. H. Mason, F.C.S., in the chair.

Messrs. Thomas Smyth and H. B. Steadman were elected members of the Association.

Donations to the library of the *Pharmaceutical Journal*, the *Canadian Pharmaceutical Journal*, and the *Proceedings of the Liverpool Geological Society* were acknowledged, and thanks voted to the donors.

After some discussion on the questions in the question box, the meeting adjourned to the tea-room.

There was exhibited by Mr. Armstrong a new kind of stand for burettes and other apparatus, from Messrs. Zimmerman, of London, which was considered very convenient and useful.

THE STARCHES OF COMMERCE.

Mr. Abraham said that in the *Pharmaceutical Journal* for September 5, he had called the attention of pharmacists to the fact that the starch generally supplied for medical purposes, so far as his experience enabled him to judge, was *maize starch*, not *wheat* starch, as it was required to be according to the definition of the British Pharmacopœia, by which they in dispensing medicine were bound. Starch was so generally found in the vegetable kingdom that it was difficult to say in what plants it was not present. Chemically, all starches were alike, and it was not easy to show how far they differed dietetically, or in their other practical applications. But it was very well known that in their commercial value they differed very much, and it was by no means safe to assume that one may, for all purposes, be substituted for another. The substitution of potato starch for the starch called arrowroot had been the subject of judicial proceedings, and they well knew the difference in value between Bermuda and other arrowroots. Under the microscope marked differences of form were apparent. The general structure was illustrated by the figure of two watch glasses placed in apposition with the convex surfaces outwards. But this form was subject to variations which apparently proceeded from the pressure to which the granules were subjected during their growth in the cells of the several plants from which they were obtained. The wheat starch, which he believed was formerly the only kind which was produced for the use of the laundress, had been, he believed, almost entirely superseded by starch obtained from cheaper sources, especially *rice* and *maize*.

In answer to his inquiry for wheat starch in the Journal, he had been favoured with several specimens.

Firstly. From a wholesale drug house who believed they were supplying wheat starch. He found it to be a mixture of *potato* with *rice* starch.

Secondly. From Mr. Burrell, of Montrose, who sent him a specimen of wheat starch from the Montrose Starch Company. He could hardly say however that this was adapted to medical purposes nor was it intended to be.

Thirdly. From Messrs. Parry and Garnham, of the Borough High Street, who said that it was from the South of France. This was *wheat* starch, and very pure, though not in powder. It was in the well-known *columnar masses* as defined in the Pharmacopœia, though he thought pharmacists generally wished it in powder.

Fourthly. He was favoured by Messrs. Evans, Lescher, and Evans with a specimen of wheat starch in powder, and was glad to have obtained a supply through Messrs. Evans, Sons, and Co., of Liverpool.

Lastly. He had been favoured by Messrs. Sumner and Co. with a sample which he found to be pure wheat starch.

He had intended to have acknowledged his obligations to the gentlemen he had named through the *Pharmaceutical Journal*, but at the request of the President he now illustrated the various forms of starch under the several microscopes before them.

A vote of thanks to Mr. Abraham concluded the meeting.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The second ordinary monthly meeting of the session was held in the lecture room of the Association, on Wednesday evening, December 9th. Business in connection with the grant of £50, lately made to the Association by the Council of the Pharmaceutical Society, was postponed till the next ordinary meeting, in consequence of the absence of many of the officers of the Association.

Mr. Siebold gave the second of his course of lectures on "The Detection of Adulteration in Common Articles of Food and Drink." Commencing with Beer, the lecturer said a long essay had recently been published in a foreign journal, describing modes of detecting the substitution of gentian, trifolium, and many other bitter drugs for hops; he had repeated these experiments, and did not hesitate to say that there was not one among them reliable; the indications were indistinct, and though possibly they might be considered conclusive by an expert who had devoted a great deal of time to their study, the tests were not such as he could recommend to the meeting. There were, however, some substances occasionally used to give a bitterness to beer, which might be very easily detected. Picric acid was one. Boil a piece of white Berlin wool in the suspected beer, acidulated with hydrochloric acid: a trace of picric acid will dye the wool a bright yellow; should the beer be of a dark colour the yellow tint on the wool may be obscured, in which case, after removing it from the beer, it should be rinsed, heated with a little weak solution of ammonia, and the filtered liquid evaporated to a few drops. To this a little cyanide of potassium should be added, when a deep red colour will be produced (isopurpurate of potassium); one part in a million may be thus detected.

Nux vomica.—Hofmann and Graham recommend that the beer be shaken with animal charcoal for twenty-four hours, the charcoal separated and boiled with alcohol, the filtered alcohol evaporated almost to dryness, and potash and ether then added. The ether would take up any strychnine present, derived from the nux vomica, and its presence could be easily discovered by the usual colour test (bichromate of potash and sulphuric acid).

Cocculus indicus had doubtless been occasionally used to increase the intoxicating effect of beer. The suspected sample should be treated with acetate of lead to throw down the colouring matter, filtered, the lead removed by sulphuretted hydrogen, evaporated to a small bulk, animal charcoal added, and left in contact for twenty-four hours, then removed and boiled with alcohol, and the latter evaporated, when crystals of picrotoxine would separate, and these might be distinguished by their microscopic and chemical characters.

Salt.—Beer always contains chlorides, but Bass's ale, which may be taken as a standard of perfection, will, when mixed with 7 or 8 parts of water and acidulated with nitric acid, give only a faint opalescence with nitrate of silver. Large quantities of salt are added to beer by some publicans, and must be estimated quantitatively in the usual way, should a precipitate be produced when tested as above. The alcoholic strength of beer may be determined by distilling half its volume and testing the distillate by the hydrometer. Burnt sugar may be detected by shaking the sample with a little solution of tannin, which will remove the colour natural to beer, but leave that produced by caramel.

Wines are sometimes coloured artificially. Logwood may be detected occasionally in cheap port by immersing in it a strip of filtering paper previously soaked in solution of acetate of copper and dried. In pure port wine the paper will acquire only a greyish pink colour, but in wine containing logwood it will turn sky blue.

Magenta may be detected by shaking the wine with an equal volume of amylic alcohol, and leaving the mixture at rest for a few minutes, when the amylic alcohol will separate, taking with it the magenta.

Clarets are extremely liable to adulteration with artificial colouring matters. It was formerly believed that agitation with black oxide of manganese would remove the colour from pure claret, but not from the coloured; this test is perfectly useless. The addition of dry caustic potash to pure claret will produce no coloured precipitate, other colouring matters are at once thrown down, and though it is difficult to distinguish with certainty what the adulterant may be, a wine yielding a violet or otherwise coloured precipitate with caustic potash may be at once condemned as artificially coloured. The precipitate is violet with logwood, reddish with beet or Brazil wood, pale violet with litmus, dark violet with mulberries or elderberries.

Lead is by no means rarely found in clarets. Wine-bottles in France are almost invariably cleaned with shot, and the glass becomes coated with a carbonate of lead insoluble in water, but quickly taken up by the acid wine. Orfila found lead so constantly present in the human body that he asserted it to be a normal constituent, and it is now believed that this lead was derived from the wine drunk largely in the district in which he lived. Lead is best detected by heating the wine with a little chlorate of potash and hydrochloric acid to remove the colouring matter, and when the chlorine has all been driven off, passing into the pale yellow liquid a current of sulphuretted hydrogen to precipitate the metal as sulphide.

The legality of a process known as "improving" wine has been the subject of much discussion in the hock-growing districts. It consists in adding sugar and water to the must before fermentation. In years when the grapes have imperfectly ripened, and contain little sugar but much free acid, it is evident that such an addition would render the resulting wine more alcoholic and agreeable, but less acid. Dr. Fresenius is one of those who strongly advocate the adoption of this process. Any addition to the wine after fermentation would be objectionable.

Brandy, whisky, and other spirits differ very much in the percentage of alcohol they contain, and in some cases hot ingredients are added to keep up the apparent strength. A specimen of brandy recently examined by the lecturer had the peculiar property of retaining its burning taste however much he diluted it. On evaporating this specimen at a low temperature in a water-bath, and so driving off all the alcohol, a residue, tasting strongly of capsicum, was obtained. Spirits are generally coloured with burnt sugar, and they almost invariably contain traces of tannin and astringent matter derived from the casks in which they have been stored.

Vinegar.—It was formerly believed, or stated, that the addition of at least one part of sulphuric acid to 1000 parts of vinegar is necessary in order to preserve it; and this addition, though unnecessary, is still allowed by law. Judging from an examination of many specimens it is evident that manufacturers generally avail themselves of this permission, though vinegar free from sulphuric acid may be obtained. Vinegar always contains sulphates; salts of barium cannot, therefore, be used for separating the sulphuric acid. A sample should be evaporated almost to dryness on a water-bath, and treated with strong alcohol, which will remove the sulphuric acid, leaving the sulphates behind; this is mixed with water, the alcohol driven off by heat, and the free sulphuric acid may be then precipitated with a salt of barium, and estimated in the usual way. A piece of filtering paper, dipped in vinegar containing sulphuric acid and dried on a water-bath, will be blackened.

Nitric Acid may be detected by boiling the sample with a little sulphate of indigo, which it would decolourize. Hydrochloric acid, lead, and copper, occasionally present, may be tested for in the usual manner.

The strength of vinegar can of course be ascertained by means of a standard solution of caustic soda. The numbers 22, 24, etc., by which different qualities of vinegar are known, indicate the number of grains of anhydrous carbonate of soda required to neutralize one fluid-ounce of the vinegar.

LEEDS CHEMISTS' ASSOCIATION.

The fourth meeting of this Association, session 1874-75, was held in the Library on the evening of Wednesday, December 9. In the absence of the President, Mr. E. Thompson was called upon to preside. After the election of two new members and four associates, a circular from the Hull Chemists' Association, asking for co-operation and assistance in defending a member of the trade in that town who is being prosecuted by the Inland Revenue Board for selling a mixture called "Pick-me-Up," or "Morning Tonic" without a spirit licence, was laid before the meeting, but action was deferred until further information on the subject had been received.

Mr. Smeeton then read the paper of the evening entitled, "A Beginner's Notion of Geology." In commencing he stated that in this as in other sciences, there was a boundary to knowledge which was soon reached; that, however correctly the causes of geological phenomena might be pointed out, there was an infinity of space beyond, leading upward to the primal cause of all. Such definitions as primary and secondary could only be relatively true. Still, geology could teach much, and the rational way to understand it was to interpret the past by the present, on the assumption that the same forces have previously been in operation and produced like results. Mr. Smeeton confined his remarks to two of the denuding or destructive forces, namely, water as a chemical and mechanical agent, and water in the shape of ice. He showed how water acted chemically by dissolving lime rocks and salts, which eventually were carried to the sea, and mechanically by its wearing influence as shown in every stream and river, and along every shore; so that, constantly, land and sea were changing places both now and in ages past. The action of glaciers was illustrated by scratched boulder-stones, and by diagrams showing that there was plenty of evidence that the northern half of Britain was at some remote period covered with ice, as Greenland is at the present day. The lecturer concluded by expressing a hope that though denizens of a town his hearers would devote some portion of their leisure to the study of nature in its varied forms, such pursuits being always elevating, and reminding them of the country side from which so many of them had come. Various fossils both from the coal and limestone formations were exhibited during the lecture.

A hearty vote of thanks to Mr. Smeeton, proposed by Mr. Abbott, and seconded by Mr. Longley, was carried unanimously and concluded the meeting.

HULL CHEMISTS AND DRUGGISTS' ASSOCIATION.

On Friday evening, Dec. 11, the annual supper of the members of the above Association was held at Varley's Cross Keys Hotel. Between forty and fifty gentlemen attended. The Mayor (Alderman C. Wells) presided, supported by the ex-Mayor (Ald. Seaton), Councillor J. Thompson, the President of the Association (Mr. Anthony Smith), and the Secretary (Mr. C. B. Bell). The Vice-Chairmen were Mr. W. Stanning and Mr. Wokes.

The toast of "The Queen and rest of the Royal Family" having being proposed by the Mayor, and heartily received, the President of the Association gave the toast of "The Mayor and Corporation," which was responded to by the Mayor.

The toast of "The Town and Trade of Hull," proposed by Councillor J. Thompson, was acknowledged by Alderman Seaton.

The Ex-Mayor, as President of the Chamber of Commerce, in alluding to the progress of the town during the past few years, said it was not energy alone which did so much for the progress of the town, but energy in connection with intelligence; and it might be that such societies as the Hull Chemists' Association and the literary institutions of the town had a great deal to do with developing as it were science in connection with industry. After alluding to various matter of local interest, he concluded by referring to his pleasure, as an old chemist, at being present at the gathering, and stating the debt of gratitude he felt he owed to the town by having been its chief magistrate.

The Mayor proposed the toast of the evening, that of "Success to the Hull Chemists' Association." He expressed his pleasure at the number of members having doubled during the last year. One of the chief objects of the Association was the better education of the apprentices, and he was told the lectures were attended in a manner which was satisfactory, and that the result of the educational movement was equally satisfactory. Another object of the Society was the protection of the particular trade, and he certainly knew no society or class of men requiring greater protection than, probably, the chemists. He would show his appreciation of the objects of the Society by continuing the prize which his predecessor in office offered to the students. He had great pleasure in submitting the toast of the Association.

The President (Mr. A. Smith) replied, first thanking the members of the Association for having paid him the compliment of electing him for the third time to fill the office of president. The Association was commenced six years ago, and he was proud to say that out of four of its founders, three were present. It was formed in consequence of the passing of the Pharmacy Act in 1868, and the need that was felt for such an association. The primary object was the offering of better facilities for the education of the apprentices, and it was now a matter of history that there was a development of facilities in Hull for such education, and pupils had passed most creditably. The second object was that of a trade protection society; and four years ago, mainly through the efforts of the Association, which aroused other associations, the Poisons Regulation Bill was tumbled into the waste-paper basket of the House of Commons. The executive of the Society were always alive to the interests of the trade. During the past year he was glad to say the members of the association had increased from 30 to 60. In conclusion, he returned thanks for the cordial way in which the toast had been received.

Mr. W. Stanning proposed the toast of "The Vice-President (Mr. G. Myers), the Secretary and Treasurer (Mr. Bell), and the Committee." He briefly alluded to the case now pending and affecting the trade generally throughout the country.

Messrs. Myers, Bell, and Oldham replied to the toast.

Mr. Milner gave the toast of "The Medical Profession," to which Dr. Gibson replied.

Mr. Wokes gave "The Health of the Lecturers, Messrs. Niven and Parsons," which was suitably replied to.

The toast of "The Ladies," "The Press," etc., followed.

ASSOCIATION OF CHEMISTS AND DRUGGISTS FOR WOLVERHAMPTON AND DISTRICT.

A large and influential meeting of gentlemen engaged in the practice of pharmacy in Wolverhampton and its district took place, on Friday evening, December 4, in the Committee room of the Agricultural Hall, to consider the advisability of establishing an association of chemists "having for its objects the better scientific education of its associates, and the protection, general advancement, and mutual improvement of its members."

Mr. W. Fleeming (Fleeming and Son) having been elected chairman, opened the business of the meeting by explaining at length the desirability of the commencement of such an association in the "metropolis of the black country." He stated that the increasing stringency of the examinations of the Pharmaceutical Society, without passing which no future aspirant can commence business as a chemist, caused great alarm amongst those assistants and apprentices who had not already qualified themselves. With a view, therefore, to assist these young men, it was proposed, as a primary object, to arrange for the delivery of lectures and the holding of classes upon the arts and sciences connected with the practice of pharmacy, and subsequently to establish a reference library, a museum, and a reading room. Besides this, he thought there could be no possible doubt that a union of chemists and druggists was desirable to resist vexatious legislation, and to arrange, by a series of friendly meetings, such matters of business as are of general interest to the trade.

Mr. W. Y. Brevitt (the local secretary of the Pharmaceutical Society) then formally proposed the establishment of the association. He called the attention of the meeting to numerous circulars forwarded by local associations, and said that from statistics he had obtained, he thought there could be no doubt of the feasibility of the scheme, for in towns much smaller than Wolverhampton, prosperous self-supporting societies were successfully carried on. Apart from the educational aspect of the case, he thought they ought to devise some means, as a body, to resist unjust prosecution under the Adulteration Act. In illustration of this he read a letter he had received from the Hull Association, calling upon chemists to assist in the defence of a brother-tradesman who was threatened by the Excise with an action for having sold a compound tincture of gentian as a "pick-me-up." He further cited the well-known citrate of magnesia, sweet spirit of nitre, and scammony cases, as examples of these obnoxious Adulteration Act prosecutions. He read letters from gentlemen promising their aid in promoting the movement, and called especially upon the assistants and apprentices present to do all they could to ensure the successful carrying out of the scheme.

The proposition was then seconded by Mr. Wm. Cannell, and having been supported by Mr. Wm. Reed, was carried unanimously.

After naming the Society and defining its object and work, the following officers were elected:—President, Mr. Wm. Fleeming; Vice-President, Mr. R. H. Lowe; Treasurer, Mr. Alexander Gow; joint Secretaries, Mr. W. Y. Brevitt (Darlington street), and Mr. F. J. Barrett, F.C.S. (the Hospital); and a Council of nine members of the Association and three associates.

In addition to ordinary members and associates, it was resolved to elect as honorary or corresponding members, gentlemen engaged in the medical or scientific professions who might be willing to co-operate in promoting the objects of the Association by subscriptions or other means. A code of rules was next drawn up and approved of, but it was deferred for the further consideration of the Council, who were to report upon it at the next meeting.

A discussion took place as to the relative positions of "members" and "associates," and it was resolved that the latter should enjoy all the privileges of membership, save the right of voting at meetings upon business subjects.

A letter was then read from Mr. Stokes Dewson, teacher of botany, etc., to the Birmingham Association, offering to deliver a course of lectures on botany and materia medica upon very favourable terms; this was also deferred for the consideration of the Council. At the conclusion of the meeting, which throughout was an extremely cordial and enthusiastic one, a vote of thanks was passed to the Chairman, who, in reply, expressed a wish that now the good ship was fairly launched, every one of the crew would endeavour to make the voyage a prosperous one and the enterprise successful.

Proceedings of Scientific Societies.

Carbon and certain Compounds of Carbon.*

BY PROFESSOR BARFF.

(*Continued from page* 416.)

Lecture VI.

The heating power of a liquid hydrocarbon may be determined as follows:—A weighed quantity of it should be mixed with black oxide of manganese or oxide of copper (cupric oxide). The mixture should be made to form a stiff paste; it can then be mixed with the oxidizing agent, as the coke is mixed with it, and the experiment can be performed as before described in respect to coal.

Coal gas is made by the destructive distillation of coal. The destructive distillation of any organic substance, fat, oil, vegetable refuse of all kinds, will give gases very much resembling in their composition coal gas. By destructive distillation is meant the heating of substances which can be decomposed by heat out of contact with atmospheric air; that is, in such a way that they cannot be burnt. In the manufacture of gas there is much the engineer has to do to improve the process, and an alleged improvement has been suggested by Messrs. Coffel, Thomas, and Company, the object of which is to relieve the pressure in a certain part of the gas apparatus, and thereby prevent the deposition of carbon. First of all, there is a retort made of iron or fire-clay, the end of which can be taken off and put on. Into that end the coals are introduced, and the retort being charged, the end is screwed up. The gas passes out through what is termed the hydraulic main. In this a portion of the tar is deposited, and the ammoniacal liquid. It is at this part of the apparatus that it is proposed to put an appliance, the object of which is to relieve the pressure, for the gas here under ordinary circumstances is given off from the coal very rapidly, so that there is a considerable tension inside the retort and that portion of the apparatus which is in connection with it; the consequence is that the pressure exerted by the gas is such that the gases deposit carbon in the upper part of the retort, and this deposition of the carbon of course impoverishes the gas, that is to say, robs it of some of its carbon, and, according to theory, must necessarily interfere with its illuminating properties. After the gas has passed through, and has deposited its tar, it is then passed through a series of tubes, which are kept cool by water trickling over them, and then through a condenser, by means of which other liquid products that come off in the state of suspension or vapour with the gas are condensed and run down into a tank.

A "scrubber," is used for the purpose of purifying the gas from certain impurities; it contains dilute oil of vitriol. Then there is what is called the lime purifier, through which the gas passes and loses certain other of its impurities, viz., sulphuretted hydrogen and a certain amount possibly of carbon bisulphide and other impurities of coal gas, which it is very difficult to get rid of entirely. Other substances besides lime are used for the perfect purification of common coal gas from sulphuretted hydrogen. When the sulphuretted hydrogen gas comes into contact with the lime, an interchange takes place, the calcium takes the sulphur, and the hydrogen takes the oxygen, so that water and sulphide of lime are formed. In this way the sulphuretted hydrogen is decomposed. In small country towns lime only is used to purify the gas, and lime does remarkably well, but there is an objection in large cities like London, to the extremely offensive smell of this sulphide of lime. In the country, people do not seem to care so much about it. This sulphide of lime is not a waste product, for after it has been exposed to the air for some time the sulphur becomes oxidized, and sulphate is formed, and if the operation be allowed to go on to its full extent, so that the whole of the sulphur is oxidized into sulphate, then it makes an excellent manure for the fields, although it would be very injurious to vegetation to put it on the ground before the oxidation had fully taken place. It used to be thought that if the lime were continually renewed in the lime-scrubber it would more perfectly purify the gas from the sulphur; but sulphur exists in two forms in coal gas, in the form of sulphuretted hydrogen, and in that of bisulphide of carbon. Now we have in the one case carbonate of the oxide of lime, and in the other the sulphide of lime, CaS, uniting with carbonic sulphide. Carbon bisulphide will not unite with lime, but it does unite with sulphide of calcium, if there be present in the scrubber some sulphide of calcium; that is, if only a portion of all that which has been already acted upon by the sulphuretted hydrogen be replaced, then the carbon bisulphide coming off with the coal gas will be taken up by the sulphide of calcium which is in the scrubber, whereas the carbon bisulphide coming off with the coal gas will not be taken up by the calcic oxide or lime. Therefore it is a matter of importance that there should be present some of this sulphide of calcium in order to take up the carbon bisulphide. One of the principal impurities in coal gas is ammonia, which is got rid of by means of sulphuric acid used in a dilute state. The purification of coal gas from ammonia by this means can be made quite perfect. If we pass into a burning jet of coal gas a small quantity of ammonia gas, the flame will immediately become less luminous. This illustrates how these impurities injure the illuminating power of coal gas. They do it by taking away heat. In order to get the maximum of illumination there must be a certain amount of heat. Ammonia gas will not burn. It is stated that it burns at a high temperature, but it is not the ammonia itself which burns; the ammonia is decomposed, and the hydrogen of which it is partly composed, burns; therefore, a certain amount of heat is wasted in the decomposition of the ammonia gas before the hydrogen burns. This leads to the mention of the subject of air gas, or gas formed by the passage of atmospheric air over red-hot carbon, and then passed through some petroleum oils in order that it might become saturated with them, and so become illuminating. There is a *primâ facie* objection to this. In atmospheric air there are four volumes roughly of nitrogen, and one of oxygen, or more correctly, 21 of oxygen, and 79 of nitrogen. Then if we convert that oxygen into carbonic oxide we have four volumes of nitrogen holding, it may be, in suspension some of these liquid hydrocarbons, but not contributing one single iota to their combustion. It is quite certain that there must be a difficulty which is not at present got over. Now in water gas, where steam is passed over carbon, we get carbonic oxide and hydrogen, which are both combustible gases, but in passing air over carbon we get a quantity of nitrogen, which is worse than useless, for it takes away heat.

Hydrated oxide of iron absorbs sulphuretted hydrogen gas very readily, and therefore is an excellent purifier of coal gas from this very great impurity. There need be no waste of iron, because the sulphide of iron, on exposure to atmospheric air in the presence of moisture, is again oxidized, and the iron oxide can be recovered, so that it is not an expensive process if care be used in its application.

Most London coal gas is thoroughly purified from sulphuretted hydrogen. Therefore, the indications of the presence of sulphur given upon the combustion of the coal gas is not resulting from the presence of sulphuretted hydrogen, but of bisulphide of carbon. Sulphuretted hydrogen, when burnt, forms water and sulphurous acid; carbon bisulphide forms carbonic acid and sulphurous acid. It is, therefore, important that this bisulphide of carbon should be got rid of from coal gas; for if gas be giving off this sulphurous acid in large quantities, which in the presence of moisture—and moisture exists largely in all rooms—is converted into sulphuric acid; as the draught

* Abstract of a course of Cantor Lectures, delivered before the Society of Arts.

generally takes it to the walls, and the moisture gets condensed on the walls, the sulphuric acid is deposited there, and if it comes into contact with substances easily destroyed by it, the destruction produced will be great. The effects on the constitution may not be particularly bad, because the quantity at any given time is very small; but in a library, or in a room full of paintings, where gas is burned every night for many hours, the sulphuric acid which is formed and condensed on the walls must do a certain injury to them; and it has been found, without doubt, to have committed great ravages on the binding of books, and also on pictures which are affected by acids. If a picture be not protected by glass or varnish, such colours as ultramarine, which are affected by acid, will be very considerably damaged by the continued action of sulphuric acid resulting from the burning of coal gas, because ultramarine is always destroyed by acids.

Bisulphide of carbon, as is known, is a very inflammable substance, catching light at a temperature far below that required to produce a gas flame. To get rid of it has been a great difficulty to gas manufacturers for a long time past. We can get rid of it well enough in small quantities in laboratory experiments, but to get rid of it on a large scale in a manufactory is very difficult. Several processes have been adopted, and a certain portion can be got rid of by passing it through lime which has already absorbed the sulphur from the sulphuretted hydrogen. That would take away some, but not the whole. If hydrogen gas be charged with the vapour of carbonic sulphide, and the two be heated together, the bisulphide of carbon will be decomposed, and sulphuretted hydrogen will be formed. Suppose coal gas containing hydrogen and bisulphide of carbon be heated in its passage through certain pipes, the hydrogen will decompose the bisulphide of carbon, and sulphuretted hydrogen will be formed, and there is no difficulty whatever in absorbing sulphuretted hydrogen. But then, it may be said, if olefiant gas be passed through a red-hot tube, carbon is deposited, and if carbon is deposited, then the illuminating power of the gas is destroyed to a considerable extent. This is true, but Mr. Vernon Harcourt states that if the gases are passed through tubes heated to a low temperature, such as does not cause the deposit of carbon, it will yet be sufficiently hot to cause the decomposition of bisulphide of carbon.

To pass on to the subject of the means by which heat is communicated from body to body, and the way in which temperature and heating power are measured, because that is what we have to consider in constructing stoves and economizing heat in all illuminating and cooking apparatus, and in fact in all processes where heat is employed. It is said that half the quantity of heat produced by the combustion of coal in this country is lost by the way in which we burn our coal. As a general rule, in our fire-places we allow half the heat at least to pass up the chimney without giving the slightest benefit.

Heat passes from one body to another in three ways—by conduction, convection, and radiation. Metals are the best conductors of heat; then come stone, wood, woollen materials, etc., which are not such good conductors. Why are metals good conductors, and wool, worsted, and cotton wool bad conductors of heat? It can be partly explained in this way. Take a bar of metal of considerable density, the particles of which are very close, and put it to the ear and strike at the end of it, and then take a metal, the particles of which are not in such close contact; it will be found that according to the density of the medium so is the sound more perfectly conducted to the ear—the more dense the material used the more perfect the sound. For instance, at the top of a mountain sounds cannot be heard at a distance, because the air is very light, whereas those who have been down in diving bells tell us that all noises sound like thunder because the air is so dense. So that a dense medium serves as a better conductor of sound than one which is not so dense. Now, heat does not travel as sound does, but it travels through undulations—not of air but of an imponderable ether—but it can be imagined that those metals which are more dense, and whose particles are more close together, would be better conductors than those whose particles are less densely packed together, for this ether is supposed to permeate all matter. I am not sure but that this, as to the density of all metals, may be subject to corrections, but the general principle is right, for a dense substance conducts heat readily, but air, for instance, which is not such a dense substance, does not conduct heat like a metal. Cotton wool and wool from a sheep are made up of a number of tubes, and these tubes contain air, and it is, no doubt, to a great extent because those cavities contain air, that wool and such substances are extremely bad conductors of heat. In foreign countries, more than in our own, people use double windows in winter, allowing a space of three or four inches between the two, and these are found to keep a house perfectly warm. The reason of it is that you have the air confined between the two windows, and the air being a bad conductor of heat, does not allow the heat to escape from the apartment. Air, when it is still, is about the worst conductor of heat that we know of, but there is a difference between air fixed and air in motion. Liquids, also, are bad conductors of heat when stationary, yet if they can be made to travel they conduct heat readily. In the application of heat to cooking purposes we have to make much use of good non-conductors as well as of good conductors. The temperature of a room may be uniform, but if we put the hand upon the marble mantelpiece we find it to be colder than if put on the wall. On the other hand, if it be put upon the blade of an iron knife it is felt to be colder than the marble. This is simply because metal is a good conductor of heat, and takes the heat away from the hand, although it is of the same temperature as the marble. Marble is a better conductor than the wall, and therefore the hand gets colder when placed on it than when it is placed on the wall.

So much about the conduction of heat. When air or any liquid is warmed, it rises, and when it is cold it descends, and so circulation is set up, and that is the principle on which water is used for the purpose of heating houses. The hot water goes to the extremity of the pipes, and the cold comes back to be warmed.

Heat, from any source, say a fire, warms the contents of the room by radiation. If a hot iron ball be put in the focus of one of a pair of conjugate mirrors, the heat will be reflected from that mirror on to the other, and in the focus of the second mirror an easily inflamed substance will demonstrate that the heat radiated can also be reflected. This principle is applicable to, and has been applied to fire-grates, and has also been applied to warming apartments of all kinds.

Parliamentary and Law Proceedings.

Prosecution under the Adulteration Act.

At the Southwark Police Court, on Thursday, December 11, Richard Barrow, grocer, St. George's Road, was summoned by the Sanitary Inspector for St. George's Vestry, for selling arrowroot strongly adulterated with tapioca, starch, etc. The Inspector said that on the 28th ult. he caused to be purchased a quarter of a pound of shilling arrowroot at the defendant's shop, and at the same time he told the defendant that he was going to have it analysed, and invited him to accompany him. He declined to do so. Witness took the arrowroot to Dr. Muter's and left it to be analysed. Witness produced Dr. Muter's certificate, showing it to be adulterated with tapioca and starch. The defendant said he sold it as he received it, and was not aware it was adulterated. The magistrates ordered him to pay 4s. 6d. costs, and recommended him to communicate with the wholesale dealer who supplied him.—*Times.*

Attempted Poisoning by Corrosive Sublimate.

William Thomas Cherry, 32, was indicted at the Central Criminal Court, before Mr. Baron Amphlett, for feloniously attempting to administer to his wife, Emma Cherry, a quantity of corrosive sublimate with intent to murder her.—Mr. Beasley and Mr. Mead prosecuted; Mr. Warner Sleigh appeared for the defence. —The prisoner and his wife lived at Bath Street, St. Luke's. They occasionally had quarrels, but nothing serious resulted from them. They were both in the habit of going out to work during the day, the man being employed as a smith, and the woman in some occupation as a seamstress. Some sugar had been purchased on a Saturday two or three days before the occurrence took place, and on the following Tuesday the prosecutor took a portion of the sugar with her, and put it in some coffee, but the taste was so disagreeable that she threw the coffee away. She tried the sugar a second time, and with the same result, and this led to an inquiry. It was ascertained that the sugar contained a large quantity of corrosive sublimate, and the question was how it could have come there except by the agency of the prisoner. It turned out that the employer of the prisoner was in the habit of using corrosive sublimate in his business, and shortly before the alleged offence was committed he had placed in a cupboard a portion of the noxious ingredients, and that he missed it when the discovery was made. The prisoner clearly had access to this cupboard, and the evidence left no doubt that he had taken it from its place of deposit and put it in the sugar with the intention imputed to him in the indictment. The Jury found the prisoner guilty, and the learned Judge, after making some appropriate observations upon the atrocity of his conduct, sentenced him to twenty years' penal servitude.—*Standard.*

Review.

On the Various Forces of Nature and their Relations to each other. By Michael Faraday, D.C.L., F.R.S. Edited by William Crookes, F.C.S. London: Chatto and Windus. 1874.

At this time, when a knowledge of the scientific principles which accord with the varied phenomena we see around is becoming daily to be considered of more and more importance as a branch of the education of the young, it is especially interesting to note the issue of such books as that we have before us. The volume contains a series of lectures, delivered originally before a juvenile audience in the Royal Institution, of a character equal with the former productions of one whose loss will be felt by scientific investigators for many years to come.

The lecturer, after a brief introduction respecting the universality of "forces or abilities to do things or powers," accompanied by one or two simple and most evident illustrations of their exercise, remarks that he "shall gradually proceed to distinguish these powers one from the other, and compare the way in which they combine together;" and this plan he carries out in the first (from which we have quoted) and five following lectures which form the course.

The force of gravitation occupies the first and part of the second lecture, and is followed by cohesion, to which, in its turn, chemical affinity succeeds. This extends over the latter portion of the third and first part of the fourth lecture, which is terminated by a description of many of the phenomena accompanying heat. The fifth lecture deals with the forces of magnetism and electricity; whilst a fitting finale to the course is found in the sixth, on the correlation of the physical forces.

A lecture upon lighthouse illumination is added, in which, after alluding to the labours of Buffon and Fresnel in this department, the speaker very strongly advocates the general adoption of the electric light for the mariner's guidance.

The leading characteristics of the work are the great adaptability of the lecturer's words to his audience, the clear and forcible manner in which truths, often considered too abstruse for children to understand, are put, and the simple, felicitous experiments adduced in support of the statements.

These experiments in many cases are such as could be performed at home without the aid of elaborate apparatus, *e.g.*, when it is wished to exemplify that light and heavy bodies would fall through air at the same rate if the resistance of the latter is excluded, the method suggested is to take a coin and a round piece of paper a trifle smaller in diameter; place the latter upon the top of the coin, so that it does not meet with any resistance from the air; then, upon both being dropped together from a height of two or three feet, the paper will reach the ground as soon as the heavier piece of money.

There are a few useful explanatory notes appended to the volume, and in one of these we might suggest an alteration which would render it more in conformity with prevailing chemical theories. Note 16, sect. 3, calls the colourless gas evolved by the action of copper turnings upon dilute nitric acid binoxide of nitrogen, and states that it is formed of one atom of nitrogen and two of oxygen. This is now called nitric oxide. As in many chemical works the formula NO_2 is used for a totally different substance, viz., nitric peroxide, a gas not colourless, but of a deep orange hue, some embarrassment would probably be caused to the young student.

An abundant supply of woodcuts embellishes the work. These are in the main correct, the principal exception being that illustrating the electrolysis of water, on page 92, in which the volume of oxygen would appear—contrary to fact and to the text—to be twice as great as that of hydrogen.

In conclusion, we are convinced that, as a preparation to the more careful study of natural phenomena, no better book could be placed before children than this.

The Good Old Times.

Sir,—I read the letters from time to time appearing in the Journal from gentlemen clamorous for early closing, shorter hours, less work, etc., and I have read the letter from "A Dissatisfied Master" on the subject. From that gentleman's point of view, I think much more might be said. I would ask "An Examined Assistant" if furthering his master's—I beg his pardon, his employer's—interest would be his first consideration? Would he be much surprised at the expiration of twelve months' servitude were his employer to say to him, "The returns of my business have considerably increased during the past year, to which your industry and zeal have much contributed; I therefore shall be pleased to make an extra increase to your salary?" I fancy, if he knows himself, he will say, "No" to my first question, and admit that he would be absolutely astounded to receive such testimony to the value of his services. I rather think he would desire to obtain that situation which offers a minimum amount of work, provided it was not accompanied by a minimum amount of pay. And if so, he assuredly is no man of business, and not likely to do much good either for an employer or for himself, although he may have the high honour of writing so sounding an affix to his name.

On reading his proposed "second stipulation," I could not help exclaiming—and I take it I was not singular—"what next, and next?" I could perhaps understand such a proposition if assistants were workmen who never could become employers, but the assistants of to-day will be the masters of to-morrow. And here I would ask, who are the head and chief offenders in keeping shops open late at night, men who have old-established businesses, the generation going out; or those who have newly-established businesses, the generation coming in? My experience tells me that it is decidedly the latter, many of whom perhaps were but yesterday the most noisily clamorous for early closing. What sort of business can "An Examined Assistant" have been employed in, when he talks of "unemployed time during business hours" when "works on pharmacy and the allied sciences could be studied?" I have never had experience of such. A well-managed retail business, the same as a wholesale, would have constant and abundant employment for the employés during business hours, and in such a business an assistant, if he were wise, would desire to be engaged. Possibly for unhappy discontents, like "An Examined Assistant," a glance at what they have escaped by being brought on the stage of these latter times may prove a solace. Take an instance—no fancied one. Apprenticed before fourteen and a half. Opened shop at 6·30, so long as it was light; and, so long as it was light enough, rose at 4·30 to study or play cricket, and as the church clock pointed to 6·30—punctual to the minute—struck wickets, dropped bat and ball, and assumed in their stead the apron and dusting cloth. At 8 o'clock precisely passed from the shop to the breakfast room—a room with no light but that borrowed from the shop. By that hour the shop from end to end, and from ceiling to floor, had been thoroughly dusted, and on Mondays the shop windows in addition had been cleaned. The window-shutters were put up at 10, the shop closed at 11. Work relaxed at 9, save on Saturdays, then it might be said to be continuous till 11, barring a brief interval for supper—generally on that night a treat of tripe. The dormitory an attic, without chimney or other ventilation, in which for some time three persons slept—assistant and apprentice in one bed, and errand lad in a second. No "evening out" during the week was ever heard or dreamt of. On Sundays shop kept open from 8 a.m. till 11 p.m. When the apprentice was able, he alternated Sunday duty with the assistant, and when he was sufficiently competent and old enough, the assistant's services were dispensed with. And then the apprentice's hat was sometimes known to experience the luxury of resting undisturbed in its box for six weeks at a stretch, each successive Sunday being spent by the apprentice—not his hat—in the little room with the borrowed light. And, it may appear incredible to "An Examined Assistant," the apprentice anticipated with as much pleasure then the return of the seventh day as he ever has since, for he was fond of reading, and the amount of Sunday trade offered but little interruption.

As a proof that all situations at that time of day were not widely different from the one described, I may mention that in one of the first situations the apprentice held as assistant, the proprietor of the business said to him, "I don't think the master should be expected to do so much Sunday work as the assistant, and therefore I expect him to attend to the shop two Sundays out of three, and I attend the third." That meant absolute rest for the assistant's hat twenty days out of each twenty-one. As the master never went to church, nor ever stirred out on a Sunday, and was able to indulge in any amount of out-door recreation, had he pleased, during the other six days, while the assistant could only hope to do so on the seventh, this—though not at the time—did, in after-years, strike the assistant as rather selfish. So also did his master's hint that as the assistant's home was not more than twelve miles distant, he supposed he would go thither on his "Sundays out." He evidently did not desire that the assistant should have a cut of his mutton on a day that he did nothing to earn it, and the assistant being, perhaps, over sensitive and modest, could not appear blind to the hint; and so every third Sunday, regardless of the weather, undertook a journey of twenty-four miles, generally at an expenditure of shoe-leather and muscle, not relishing the inroad that travelling regularly by coach or omnibus would have made in his salary of £30 per annum.

My letter is already longer than I intended it to be. I draw suddenly to a close. I may, in a future communication, endeavour to administer further consolation to "An Examined Assistant," and others like unto him. In conclusion I would simply say that I rejoice that what I have depicted are things of the past, and that with regard to "Sundays out," I think that in establishments where only one or two are kept, the principal should place the seventh day entirely at the disposal of his employés, content himself to do, as a rule, whatever Sunday work is required.

Veritas.

Pharmaceutical Education in Ireland.

Sir,—The subject of Irish pharmacy and the extension or formation of a Society of pharmaceutists for the sister isle has often, and long occupied the pages of your Journal, but has led, as yet, to no practical result.

I remember during a three years' residence with the largest firm of apothecaries in Dublin, taking up the Journal one evening in 1868, I think, and finding that Mr. Abraham had given notice that it was his intention to move, at the next meeting of the Council, that steps be taken to assimilate the laws relating to pharmacy in Great Britain and Ireland.

I wrote to Mr. Abraham on that subject, and I also remember that he seemed to have an impression similar to that mentioned in your article on the Irish pharmacy question, namely, there is an idea entertained by some, that should such an act become law, there would be, as you say, an exodus of chemists and druggists, of all degrees of efficiency, making their way to Ireland, eager to clutch the pharmaceutical prizes dropping from the hands of the apothecaries.

During my sojourn in Dublin, I had opportunities of hearing and knowing the feelings of a large number of medical men there on this point, and I am simply stating what I know to be the case—that the largest number of physicians, practising as such, are decidedly in favour of the extension of the Pharmaceutical Society of Great Britain to the sister isle, or of the establishment of a Pharmaceutical Society in Ireland altogether separate and distinct from "the Hall." Apothecaries of known reputation and standing, possessing powerful local interest, would have nothing to fear, and much respecting which to rejoice, as they could, probably, so far as the present generation is concerned, take the lead in the management and general government of such Pharmaceutical Society, they being really, truly, and practically pharmaceutists and not practitioners.

For my own part, I would fall in with Dr. Leet's view of the matter, namely, that pharmaceutists alone should be recognized, and thus the Major qualification would necessarily be insisted upon; and so this anticipated current of chemists and druggists of all degrees of efficiency would set another away.

I believe the Apothecaries' Hall of Ireland is favourable to this scheme, and I imagine from Professor Tichborne's name being constantly mentioned in connection with some of the classes, that he has done, and is doing, much to smooth the way for an amicable arrangement, for the ultimate good and advancement of pharmacy.

In some parts of Ireland I know there is much need of such an Act, to supply the inhabitants of large districts with necessary medicines, and to these people and places such an institution would be of the greatest possible value; but in Dublin, Belfast, and Cork there are very superior, and very extensive houses, conducted strictly as compounding establishments, well able to compete with any London or Edinburgh firms, and it is quite a mistake for anyone to imagine other than that in the above places pharmacy has some most able and distinguished representatives.

In conclusion, I will only express a hope that ere long some such Act as that mentioned may have passed into law, so that when other societies are holding conferences and exchanging mutual greetings and friendly cordialities with our Irish brethren, we, too, as pharmacists, may be permitted to hold conferences in Dublin and Belfast, and partake of, and share in the hospitalities so liberally and lavishly bestowed on members of the other British Associations.

Arthur Wm. Postans.

35, *Baker Street, W.*
November 30th, 1874.

Preservation of Infusions.

Sir,—I was surprised to read, in the Journal of the 5th inst., the following remarks made by Mr. Martindale:—"He believed that Mr. Barrett had once used carbolic acid for preserving infusions, but that substance, to the extent that Mr. Barrett used it, was very dangerous in consequence of its poisonous action."

I beg leave to deny this statement *in toto*. I certainly, some years ago, plugged the mouths of infusion bottles with carbolized wool, and tried carbolic acid with other antiseptics as infusion preservatives against chloroform, but only as an experiment. Of course I never gave (or intended to give) carbolic acid preserved infusions to patients, and as I have not had the honour of speaking more than a dozen words to Mr. Martindale in my life, I conclude that some good-natured mutual friend has played us both a practical joke.

I quite think that it is not likely chloroform will prove to be a satisfactory preservative for ordinary infusions. In hospitals, however, where concentrated infusions are used, and after obtaining the sanction of the prescriber, its use is, I think, quite unobjectionable. No one can doubt the immense superiority of the fresh infusion over the concentrated, but how can the former be kept in readiness for dispensing in hospitals?

Frederick John Barrett.

Wolverhampton and Staffordshire General Hospital.

Amorphous Phosphorus.

Sir,—If Mr. Postans flatters himself that I attached the least "importance" to the "purport of his letter" in the Pharmaceutical Journal of November 14th, he is so far mistaken. I replied to the only question necessarily connected with the observation I made when the paper was read, and I did it at the proper time and in the proper place at the next month's evening meeting, directly after the reading of the minutes.

The other questions refer to the medical literature rather than to the pharmacy of the subject.

If Mr. Postans and his medical coadjutor waited a month for my reply as to dose, etc., I fear that Pharmaceutical research on the one hand and Therapeutic Science on the other, will not be much advanced by either.

I have yet to learn that pharmacists are as a rule averse to making reasonable experiments in aid of Therapeutics, or that they require to be reminded of the important services they may render by doing so, but many of them have a conscientious objection to "floating" rubbish which is a blot to Pharmacy and no credit to medical science.

I may be excused reminding Mr. Postans that the tone of his letter is personal in the extreme. In the discussion which took place I advanced no "useless theory" or "hypothetical statements;" I merely related a fact within my own knowledge; he will not therefore be surprised at my declining to reply to any further communication.

Personal observations in discussions of this nature do not advance science and they are quite unnecessary, but they tend to dissociate the profession of a gentleman from that of a pharmacist.

Thomas Greenish.

20, *New Street, Dorset Square.*

Sir,—The statements contained in the letters of Messrs. Corder and Perkins, relating to the preservation of infusions, I can fully corroborate by my own experience.

The method first came under my notice some six years ago, when I came to reside with Mr. Humpage at Turnham Green, who then informed me that it had been his practice so to keep them for years, and he added that only in exceptional cases did they go bad. Our *modus operandi* is simply to heat the infusion to about 190° Fahrenheit, and then, fill up some six or eight ounce bottles completely to the brim, so as to run over, and tie them over immediately with bladder. The bottles we always warm, so as to prevent fracture when the hot infusion is put in. Care should also be taken that the bladder used be perfectly air-tight. As the infusion cools a vacuum forms, causing a concave appearance of the bladder, and as long as it presents this appearance the infusion is good. Occasionally a certain amount of decomposition takes place, gas is formed, when the concave surface becomes convex, and on piercing it a slight report is heard; the infusion then of course is valueless.

While on the subject I may remark that lime juice, which is so liable to decomposition, may in this manner be preserved fresh and good for almost any time. The objections to the use of chloroform are, I think, too obvious to need repetition, and I quite agree with Mr. Corder that the average of prescriptions containing it and its preparations is very much less than stated by certain eminent pharmacists at the late meeting.

Frederick George Gudgen.

Turnham Green, W.

Proposed Conference of South London Chemists.—Mr. Samuel Lacey, of Vassall Road, North Brixton, writes to suggest the desirability of holding a conference of Pharmaceutical and Non-Pharmaceutical Chemists of South London, which shall have for its object:—1. The formation of local committees for organizing a mutual society to promote the interests and advancement of the profession. 2. To promote early closing. 3. To establish a library and reading room. 4. To promote periodical meetings for the interchange of professional experience and ideas. 5. To aim at establishing a permanent school of chemistry to facilitate the acquirement of a sound knowledge of all branches of science in connection with pharmacy. Should these proposals be approved of, a meeting could be arranged (by those willing to form a committee *pro tem.* forwarding their names and addresses to Mr. Lacey or as under), which could be advertised in due course, and a preliminary meeting held to decide upon the time and place for holding the conference. Mr. J. Bailey, Chemist, Clapham Road, will be glad to receive any names and addresses of those wishing to cooperate in the movement.

R. U. Clark.—Bicarbonate of Soda 1 oz., powdered Castile soap ½ oz., sulphate of potash ½ oz., sugar of milk ½ oz., orris root 4 oz., oil of bitter almonds 4 drops. Coloured at pleasure. (Beasley).

W. Bird.—The book is out of print, but we believe some copies are still held by various booksellers. Apply to Mr. Kimpton, Bookseller, Holborn.

"*Chemist.*"—Yes, if he is on the Register of Chemists and Druggists.

"*Horns.*"—Perhaps the best way would be to make a fresh solution, and use nitrate of copper.

J. W. S.—The solvents of ordinary shellac will dissolve white shellac provided it be freshly prepared and has not been exposed to the air.

A. H. Claypole.—You will find directions for preparing and using the tests mentioned in 'Sutton's Volumetric Analysis,' or any manual of Water Analysis.

R. M. Gould.—The pamphlet is published by Baillière, Tindall and Cox, King William Street, W.C.

Communications, Letters, etc., have been received from Mr. Bird, Mr. Bell, Mr. Howard, "A Pharmacist."

REMARKS ON JAVANESE CALISAYA BARK AND ON QUINIDINE IN REFUTATION OF SOME STATEMENTS IN DR. HESSE'S PAPER ON THE SAME SUBJECT.*

BY DR. J. E. DE VRIJ.

The just reputation of Dr. O. Hesse as a chemist in general, and particularly in relation to the chemistry of the cinchona alkaloids, and a wish not to lose the confidence which I am happy to enjoy of many readers of this periodical, compel me, much against my inclination, to refute the following statements which occur in the above paper:—

1. That the Calisaya originally introduced into Java is not *Cinchona Calisaya*, Weddell, but another species, because its bark contains quinidine, which alkaloid does not occur in Calisaya bark from Peru or Bolivia.

2. That when, in 1859, I extracted quinidine from the bark of the above-mentioned species, my proof of this fact was unsatisfactory, because at that time I was not enough acquainted with the more frequently occurring Cinchona alkaloids.

3. That Dr. Hesse found in a Javanese Calisaya bark, which I had presented to him, 3·18 per cent. of quinidine, whilst I obtained only 0·50 per cent. of that alkaloid from the *same* bark.

4. That sulphate of quinidine, which really deserves that name, very rarely occurs in the trade.

Ad 1m.—Although I quite agree that the plants originally introduced into Java do not belong to a valuable variety of *Cinchona Calisaya*, Weddell—so that I very much prefer the later introduced variety, called *Ledgeriana* by Mr. Howard—I, nevertheless, am obliged to maintain that they really do belong to *Cinchona Calisaya*, Weddell, and to no other species, notwithstanding the large amount of quinidine sometimes contained in their bark. My authority for this assertion is Dr. Weddell himself, who visited me in September, 1855. At that time the Cinchona seeds sent by Dr. Hasskarl from Peru had produced seedlings in the botanical garden of Leiden, and as there was a rumour that these young plants did not belong to valuable species, the Colonial Minister, Mr. Pahud, to whom I had communicated the expected visit of Dr. Weddell, was very anxious to have his opinion about this matter. The Minister expressed to me his wish to meet Dr. Weddell, but not before this gentleman should have seen the plants. I, therefore, on the 24th September, 1855, accompanied Dr. Weddell to Leiden, where my friend, Professor de Vriese, showed to him the young Cinchona plants of the kind of which the greatest number had been sent a few weeks before to Java, under the care of Dr. Junghuhn, on board of the ship, "Minister Pahud." The plants showed to Dr. Weddell belonged to two species, one of which he immediately recognised to be *C. Calisaya*; he did not, however, recognise the other species, which was described some years later by Mr. J. E. Howard, under the name of *C. Pahudiana*. I returned with Dr. Weddell from Leiden to the Hague on the same day, and accompanied him in the evening to the Colonial Office, where I left him with the Minister, who was expecting him there at 8 o'clock p.m.

The fact that after the conference of the Minister with Dr. Weddell, the remaining Calisaya plants were sent, like the former, under *that* name to Java, proves that Dr. Weddell maintained the opinion which he expressed at Leiden, also in presence of the Minister. Therefore, as long as Dr. Weddell does not retract his opinion, I shall hold that the Cinchonas originally imported into Java under the name of *Calisaya* belong to the species described by Dr. Weddell under the name of *C. Calisaya*.

Ad 2m. I readily agree that in 1859 I was much less acquainted with the Cinchona alkaloids than I am now; but at that time there was none of them with which I was so well acquainted as with the alkaloid called "quinidine" by Henry and Delondre, who discovered it in 1833, and maintained in 1853, under that name, by Pasteur. It was at that time the only Cinchona alkaloid which I succeeded in obtaining *chemically* pure. I feel at liberty to make an appeal to Mr. J. E. Howard, who can state by experience that as early as 1856 I was thoroughly acquainted with Pasteur's quinidine after my discovering its interesting compound with hydriodic acid.* The slight solubility of this compound in water, combined with the powerful dextrogyre rotation of the alkaloid, which I never failed to ascertain, as my laboratory in Java was provided with a first-rate polarizing apparatus made by Dubosq, rendered it impossible for me to have been mistaken when I stated in 1859 that the Javanese Calisaya contained a relatively large amount of quinidine. But there is still another proof that the quinidine discovered by me in 1859 as existing in Javanese Calisaya is really the same alkaloid described under *that* name by Pasteur, for everyone who has studied the International Exhibition at London, in 1862, may have seen the crystallized hydriodate of quinidine prepared by me from Javanese Calisaya bark, and exhibited, together with other products of Javanese Cinchonas, by my colleague, Dr. Junghuhn, who was rewarded with a medal for these contributions. This same hydriodate of quinidine is still existing in the Colonial Museum at Harlem, where Dr. Hesse and anyone interested in the matter may see it.

Ad 3m. Every chemist who has once prepared the hydriodate of quinidine, and has thereby become acquainted with its properties, will agree with me that the quantitative determination of the alkaloid called quinidine by Pasteur, and conchinine by Hesse, is so very easy that a difference so great as between the numbers 3·18 and 0·50 is really an impossibility. I agree that the Javanese Calisaya bark with which I presented Dr. Hesse about a year ago was really grown and collected by me at Tjibodas, in Java; but I positively deny that this bark is identical with that which I analysed in 1859. The bark then analysed by me was a product of several young Calisayas which had died, and was wholly sacrificed to that analysis, so that *nothing* was left. The bark in which Dr. Hesse states he has found 3·18 per cent. of quinidine is of a later period, and I made him a present of it so that he might convince himself of its large amount of quinidine. I am quite at a loss to understand how Dr. Hesse can quote from p. 79 and 94 of my paper a *quantitative* analysis of the *different* alkaloids of Calisaya bark, for on page 79 I find only that I obtained from 50 grams of Calisaya bark 2·155

* See before, p. 482.

* In his letter, dated December 30th, 1856, Mr. J. E. Howard wrote to me about this subject, "Your letter has given me much pleasure, and proved very interesting, more especially so your very beautiful reaction for quinidine by means of hydriodate of potash. This I have put to the proof, but not as yet the hydriodic acid."

grams = 4·31 per cent. of rough alkaloids, and on page 94 the only number which I can find is that of 46°·5, indicating the molecular rotation of quinic acid. The only explanation which I am able to give of this misquotation is, that the paper, of which I gave a copy to Dr. Hesse, is written in Dutch, so that it is possible that he did not quite understand it. The quotation of any page of this paper is, however, quite useless, as it is a copy of a paper published originally in the journal called "*Natuurkundig Tijdschrift van Nederlandsch Indie.*" As the copy cannot be had, in order to put the reader in the position to compare the accuracy of the quotation, a quotation ought to refer to the pages of the journal in which the paper has been inserted. I therefore correct Dr. Hesse's quotation by stating that p. 79 refers to p. 255, and p. 94 to p. 270 of the mentioned journal, vol. 21, 1860.

This journal can be bought in the trade, and it is therefore now possible for the reader of Dr. Hesse's paper to judge between my statement and Dr. Hesse's.

Ad 4m. If Dr. Hesse had stated on p. 342 of the journal quoted that sulphate of quinidine, which really deserves that name, does not occur in the *German* trade, I should quite agree with him; but I must differ from him when he states that in England, like in France and in Germany, a mixture of Cinchona alkaloids freely crystallizing from ether serves to prepare large quantities of a so-called sulphate of quinidine, which however contains, according to Dr. Hesse, chiefly cinchonidine, and only by exception real quinidine. Although I am unable to judge, generally, if there be *some* truth in that assertion, because I am not acquainted with the products of all the firms who manufacture Cinchona alkaloids, gratitude compels me to acknowledge that as early as 1856 Mr. Howard presented me with *pure* quinidine, and it is chiefly to his generosity that I owe my peculiar knowledge of that alkaloid. The purity of his alkaloid was proved by me both by the polarizing instrument and by its compound with hydriodic acid. For the history of Pasteur's quinidine (= Hesse's conchinin) the following extract from Mr. Howard's letter, dated Dec. 30th, 1856, is very interesting:—"It seems to me a great pity that sulphate of quinidine is not more used commercially. I have myself tried it with excellent effect in many cases of ague, to which I have given this medicine gratuitously, and have never failed in checking the periodical returning of the paroxysms of fever. I am inclined to think that it produces less disturbance and that it may be given more freely than quinine, and the price is now low. I suppose we should sell the commercial article in large quantity at four shillings the English ounce." To this I can add that when I went to Java in 1857 I took with me a large provision of sulphate of quinidine, for which I was indebted to the generosity of Mr. Howard, and during the six years of my staying in Java I always cured my servants of ague by this sulphate with the greatest success. Although I do not know exactly when Messrs. Howard and Sons introduced the real sulphate of quinidine into the trade, it is of public notoriety that in 1867 they provided the Indian Government with pure sulphate of quinidine, whilst I am myself, through their liberality, in possession of most beautifully crystallized sulphate of quinidine.

The Hague, December 9th, 1874.

NOTE ON SPIRITUS VINI RECTIFICATUS.

BY JOSEPH INCE.

It was suggested in a recent paper on a proposed International Pharmacopœia, that the mode adopted in America for expressing spirit strength, might be recommended as another step in the direction of uniformity. The advantage of this method has the same claim for general use as the metrical system of weights and measures—one common language and one recognized standard for degrees of temperature. The gain would be on the side of mutual understanding, and ease of definite application.

To save private correspondence on the subject, the argument in favour of the American plan may thus be stated:—

In England spirit strength is described in two different ways, the first referring to pharmacy and the directions of the British Pharmacopœia; the second to excise regulations. We have then—

I. Spiritus Rectificatus = Spirit of Wine, B. P.
Specific gravity at 60° F., 0·8382.

It contains 84 per cent., by weight, of absolute alcohol.

II. Spiritus Tenuior = Proof Spirit, B. P.
Specific gravity, at 60° F., 0·920.

It contains 49 per cent., by weight, of absolute alcohol, and may be further described as Sp. Rect., B. P., 100 volumes + water *ad* 156 volumes. Sixty volumes of water are required, owing to the known law of condensation.

Excise arrangements involve another nomenclature, and we have—

(a) Proof spirit as the standard unit.
(b) Spirit over proof = O. P.
(c) Spirit under proof = U. P.

To ascertain the spirit strength we have to use Syke's hydrometer with certain precautions, or we make various calculations which resolve themselves into this—

P. S. (proof spirit) = 1.
Absolute alcohol = 100 O. P.
Water = 100 U. P.

Let it be noticed that the term Spiritus rectificatus has an arbitrary signification. The adjective does not mean rect-ified, as in rectified oil of turpentine; but weak spirit so concentrated as that it may be of official strength. Also in determining the specific gravity, it is requisite for a Frenchman to know that 60° Fahrenheit = 15·5° Centigrade. It is granted that these points are familiar to every student of chemistry, but not the less are these terms of themselves unintelligible in countries not our own, until their exact relative meaning has been ascertained.

With this may be compared the Paris system, as given in the Codex, 1866. In commercial use we find—

Alcool, syn. Esprit de Vin.
1. Alcool absolu = 100°.
2. $\left\{\begin{array}{l}\text{Alcool rectifié}\\ \text{Esprit de vin}\end{array}\right\}$ = 85°.
3. $\left\{\begin{array}{l}\text{Alcool faible}\\ \text{Eau de vie}\end{array}\right\}$ = 56°.

The degrees are those marked on the Alcoo-mètre centésimal of Gay-Lussac, the description and use of the apparatus being given in the Codex, page 13.

Its chief divisional arrangement is as follows :—
The instrument is marked off in 100 parts—

Pure { Water = 0.
Alcohol = 100.

Each division shews $\frac{1}{100}$ of absolute alcohol; necessarily in its construction allowance has been made for the laws of variable contraction.

These forms of Spiritus rectificatus are (as already said) commercial; but French pharmacy offers two more varieties.

A. Alcool Rectifié, syn. Alcool repurgatus.

This is the result of the distillation of Esprit de Vin; the first product (two-fifths of the distillate) marks 88° to 90° on the centesimal. The remainder of the distillate is used "in a great number of preparations," being obviously a weaker spirit.

B. Alcool at 95° centésimaux.

This is Alcool at 85°, digested for two days at a gentle heat with dried potassium carbonate, and then distilled.

It marks (as its title indicates) 95° at a temperature of + 15° C. Lastly, Alcool absolu = 100° at + 15° C, the standard of comparison, and is obtained by adding to each litre of this alcool at 95°, 300 grammes of finely powdered quicklime, previously slacked by water, and well calcined. After two or three days' contact in the hot room, the mixture is slowly distilled in a water-bath.

It will be conceded that this French mode of designating spirit strength is not familiar to the average English reader. When Dr. de Vrij was asked at the opening meeting of the British Pharmaceutical Conference the strength of the spirit which he used in testing the cinchona alkaloids, he endeavoured to find out the absolute strength of the spirit used in England. The answer was elicited with hesitation; but had we followed the example of the United States, there would have been no difficulty in the reply.

Spirit of wine is chiefly used in America in the form of alcohol and of diluted spirit, but it is also frequently described according to its per centage; as, for example, 50 per cent. spirit, 60 per cent. spirit, and 80 per cent. spirit, meaning that in the volume there are 50, 60, or 80 parts, *by weight*, of absolute alcohol to a corresponding number of parts of water to make 100. Thus 80 per cent. spirit contains 80 per cent of absolute alcohol (sp. gr. ·795) to 20 per cent. of water, both by weight.

Alcohol, official, in the United States' Pharmacopœia, is not absolute alcohol, but is known as "druggists' alcohol," and contains 85 per cent., by weight, of absolute alcohol having a specific gravity of ·835. This, therefore, would be popularly known and correctly described as 85 per cent. spirit. It is employed as a solvent for resins, balsams, grape-sugar, and castor oil.

Diluted alcohol, U. S. P., consists of equal parts, *by measure*, of druggists' alcohol and water, or 42 parts, by weight, of absolute alcohol to 58 of water. Its specific gravity is ·935. By our Syke's hydrometer it would be 14 under proof. This would be popularly known, and correctly described, as 42 per cent. spirit. Our B. P. rectified spirit, sp. gr. ·838, would be popularly known as 84 per cent. spirit, because it contains 84 per cent., by weight, of absolute alcohol, to 16 parts of water. Our B. P. proof spirit, sp. gr. ·920, would be popularly known as 49 per cent. spirit, because it contains 49 per cent. of absolute alcohol to 51 of water by weight. This method of naming spirits of various strengths is so simple and correct that its great advantages are at once apparent and leave nothing to desire.

It may serve at once for international assimilation and practical pharmaceutical employment.

THE INSECTICIDAL PROPERTIES OF SOME SPECIES OF PYRETHRUM.*

BY HERMANN KALBRUNER.

Some plants of the Composite family have long been used for the destruction of different kinds of insects. Thus, Mathiolus in his 'Herbal' (A.D. 1563) says of the *Conyza media* (*Conyza squarrosa*, L.) that the plant or the smoke of it will drive away fleas, gnats, and other noxious insects. The smell of *Inula Pulicaria* was held to be equally efficacious in dispersing insects, and the herb *Artemisia Absinthium* was used for similar purposes. In the Banat the root of *Inula Helenium*, L., has long been held in high esteem as a fumigant against mosquitoes, etc.

But in more recent times certain species of *Pyrethrum* have obtained considerable reputation as insecticides; the *Pyrethrum carneum* and *P. roseum*, M.B., both growing wild, and frequently cultivated in the Caucasus, having, in this respect, proved to be very superior. In the year 1846, Zacherl, a Tiflis merchant, first introduced the sale of these flowers into Vienna under the name of "Persian Insect Powder."

Notwithstanding that *P. carneum* and *P. roseum* are indigenous in the Caucasus and in Persia, they have been successfully cultivated in many localities in Europe and North America. The climate of Lower Austria suits them very well; they are found there as ornamental plants in the gardens, and they grow in northerly cool places with especial luxuriance. The author has had plants of *P. roseum* in his garden during several years, and they have supported the cold of winter without shelter.

Under the name of Dalmatian Insect Powder the flowers of *Pyrethrum cinerariæfolium*, Trev., a plant that grows wild in Dalmatia, have been used. Through the kindness of a friend the author obtained some seeds from Dalmatia, from which he was successful in raising plants in his garden, where they lived through the winter in the open air.

In order to test the effect of the different insect powders the author sprinkled some flies with the powders, and took the length of time required to kill the flies as the measure of the value of the powders. When a house fly was placed in a small flask, sprinkled with four grains of insect powder, if the powder were very powerful, there was considerable stupor at the end of one minute, followed by death of the fly after two or three minutes. The commercial insect powders behaved differently in this respect; some of them corresponding completely to the above standard, whilst others, although they quickly stupefied flies treated as above, required fifteen to thirty minutes to kill them. The druggists in Vienna purchase the whole flowers, yielded, in the author's opinion, by the uncultivated Dalmatian *Pyrethrum cinerariæfolium*, Trev., and the powder they supply is a very energetic preparation. It is noteworthy that

* Zeitschrift des allgemeinen österreichischen Apotheker-Vereines, vol. xii., p. 542.

both these entire flowers and the powder prepared from them, after being kept six years, do not suffer any particular loss of activity. The author found the powder of the flowers of *P. cinerariæfolium* cultivated by himself also to be very active.

Pyrethrum roseum, M. B., of the author's cultivation, appeared to be slower in its action, which he ascribes to the circumstance that the dscoid flowers are much more powerful than the radiate flowers, which appear to have little activity. The radiate flowers occur in *P. roseum* in much larger proportion than in *P. cinerariæfolium*; and to this fact he considers the greater activity of the latter due.

The fresh (undried) flowers of both these Pyrethrums will kill flies, but very slowly. The plant itself, powdered, appeared to be quite inactive. In a similar manner the author tested the powdered flowers of several Austrian Compositæ, and he found the following to be quite inactive in this respect:—*Chrysanthemum leucanthemum*, L., *C. Coronarium*, L., *Anthemis arvensis*, L., *A. Cotula*, L., *A. tinctoria*, L., *A. nobilis*, L., and *Inula Pulicaria*, L. The flowers of *Tanacetum vulgare*, L., and *Pyrethrum corymbosum*, Sm., appeared to have a very slight stupefying effect.

Of all the Austrian indigenous Composites tried by the author, only the powdered flowers of *Pyrethrum Parthenium*, Sm., and *P. inodorum*, Sm., exercised a stupefying influence upon flies, and that only after the flies had been dusted from one to two hours; their value, therefore, as insecticides, is very slight. In a scientific aspect it is, however, interesting to notice that up to the present time the action obnoxious to insects has only been observed in the genus *Pyrethrum*, whilst from other Composites approaching very nearly to that genus the property is absent.

Some years since, the *Journal de Pharmacie d'Anvers* contained an article, which was copied into various other journals, asserting that the insecticidal action of Persian insect powder was due to powdered flowers of *Anthemis Cotula*. As above stated, the author found the flowers of this species quite inactive, since flies which had been dusted with it were after four hours still able to fly away readily. The author conjectures that a species of *Pyrethrum* was mistaken for *A. Cotula*.

The cultivation of *Pyrethrum roseum* and *P. carneum* has already been attempted in various places in Austria. Paukert, an apothecary at Treuenbritzen, has cultivated them for several years, and in Hager's *Pharmaz. Centralhalle* (vol. vii., p. 49), has detailed his method of proceeding, from which it appears that the growth of the plants has been very successful in richly manured soil. The author's experiment also with *P. cinerariæfolium* yielded the flowers at a slight profit. But as very active flowers can be obtained from Eastern Asia and Dalmatia at a moderate price he does not think that the home cultivation would be remunerative.

PHARMACY IN DENMARK*.

BY HANS M. WILDER.

The number of pharmacies in Denmark (as is the case in most European countries) is limited by virtue of the control which the Royal Board of Health exercises over them. A privilege (licence) is granted only to persons who are recommended by the Board as competent pharmacists, and then only where a real want of a pharmacy exists. There are two classes of privileges: *real* and (chiefly since 1842) *personal*. A real privilege is transferable, and can be bought by any one who has fulfilled all the requirements of the law. (All privileges granted before 1842 are practically considered real.) A personal privilege, on the contrary, is granted only for lifetime, and is, consequently, non-transferable. When the owner of such a privilege dies, the place is open for a new competition, unless the widow, as is generally the case, is granted permission for one or more years to conduct the business under the supervision of a *provisor*.

Pharmacists are now trying to convert the "real" privileges into "personal" ones, but experience the same trouble as pharmacists do in Germany and elsewhere; and I think that Sweden is, as yet, the country which has approached a satisfactory solution the nearest. Respecting "free trade," there exists the same hard struggle, as in other countries, between pharmacists with stores and those without stores. The pharmacies emerged by degrees from the kitchen of the physician, until they became independent. The first privilege on record dates 1536 (Svane Apothek, Copenhagen); the six next, respectively, 1543, 1549, 1573, 1581, 1585, 1591. The whole number of pharmacies in 1870 was 115, to a population of 1,783,585, which makes an average of one to every 15,509; thus it will be seen that as a rule, pharmacies in Denmark must yield quite a comfortable competency.

The only collection of ordinances (pharmaceutical laws) begins 1660. Already in 1668 yearly inspection of pharmacies was insisted on, but it was first in 1672 that a full ordinance appeared, detailing, in thirty paragraphs, the duties and requirements of the apothecaries, and, incidentally, those of the physicians. I may be permitted to extract a few of the said paragraphs, in order to show that two hundred years ago the requirements were quite up to the modern standard.

None but regularly graduated physicians were permitted to prescribe. The pharmacies must be inspected at least once a year; twice or oftener, if deemed necessary. In these inspections the quality of drugs and preparations must be examined into, and whether the apothecaries in their prices adhered to the annually issued price-lists; likewise, accuracy of weights and measures. Poisons to be kept in a separate compartment (or room) under lock and key. Arsenic and sublimate only to be sold by the apothecary.

When poisons or active medicines (heroica) were prescribed, then the physician had to write out the name and quantity in full, neither abbreviation or *chemical signs* being allowed. None but graduates must keep pharmacies, and every apothecary must keep at least one examined assistant. Further, they were enjoined to let their apprentices attend the professor of botany in his excursions, and, as far as possible, cultivate medical plants in their gardens. No prescribing over the counter was allowed. All preparations had to be made by themselves, and electuaries (mithridate, etc.) to be prepared only in presence of several physicians, who had to duly label them and mark the date and quantity. In their preparations they had to conform to the Dispensatorium Hafniense, which from time to time was revised by the College of Physicians. In case of patients dying, the claim of the apothecary had precedence before any other claims. No *quid pro quo* (substitution) permitted; in case of doubt, they had to consult with the physician. No physician allowed to keep or have part in a pharmacy.

In 1753 an ordinance forbade any apothecary to keep more than one store in the same town. In 1796 appeared the first detailed poison law, which, among other things, contains the proviso that arsenic can only be sold on certificate from the respective mayor or parson, and then only one ounce at the time. An ordinance, from 1843, permits the sale of lead water without prescription.

In 1810 apothecaries were required to notify the *district physician* whenever they intended to leave town for more

---

* From the *American Journal of Pharmacy.*

than twenty-four hours, unless their assistant happened to be a graduate. In case the annual price-list was not strictly adhered to, the apothecary in fault was fined 50 dols. for the first offence, 100 dols. for the second, and if caught a third time, he *lost his privilege*. An assistant would be fined one-half, and the third time declared *unworthy to serve* in any pharmacy in Denmark. (April 21, 1812.)

The first Pharmacopœia Danica appeared in 1772; the subsequent revisions respectively were 1805, 1840, 1850, (1857), 1868. There exist, besides, collections of formulas for the use of the chief hospital, for the military, and for the poor.

Pharmaceutical life is as follows:—

The apprentice must be at least fifteen years of age, and have left high-school from one of the two upper forms. If the latter be not the case, he has to pass a preliminary examination to show that he possesses a fair school education, and is proficient in Latin.

He has to serve four years before he is permitted to take his first degree (Physikat examen).

At this examination he is required to translate the Pharmacopœia, recognize drugs, read abbreviated prescriptions, put up prescriptions, make one of the easier preparations, and show a fair knowledge of practical chemistry, poison laws and doses, and of indigenous medical botany. If successful, he is declared *assistant*, and as such has a right to put up prescriptions on his own responsibility, but is not allowed to take a charge of a store for a longer period than twenty-four hours. After further serving for a couple of years, or after attending two courses of lectures at the University, he may take his last degree, which makes him a *graduate* (candidat), and gives him equal standing with the apothecary (minus the ownership of a store).

This last examination requires him to make an official chemical preparation, one or more tests, and a qualitative analysis (of any mechanical mixture), on each of which three he has to write a report (thesis); these preparations and analysis being made, and reports written on three consecutive days within twelve hours each day, during which time he is not allowed to talk to anybody, or leave the room before his task is finished, nor are text-books allowed.

Then comes the theoretical part, which is conducted orally, and consists of questions in practical pharmacy, theoretical and practical chemistry, natural philosophy, botany, pharmacology. There are three degrees of qualification, according to the number of points made: *Laudabilis, haud-illaudabilis*, and *non-contemnendus* (praiseworthy, not unpraiseworthy, not to be despised); graduates with the last degree generally try to make the examination over again. For exceptional proficiency in all branches there exists a fourth degree: *Laudabilis præ ceteris* (praiseworthy above all others). There is one peculiarity, which obtains in putting up prescriptions, viz., that every prescriptionist must put his name on the label every time a prescription is put up; in case of mistake, it is at once traced to the guilty party.

In general, the Danish apothecaries are not permitted to sell other things but drugs and medicines (including cologne, pomatum, hair oil, chocolate); since in small places, the legitimate part of business is not likely to be sufficiently remunerative, permission is granted to deal in groceries and general sundries besides. As a curiosity, it may be mentioned that such a small apothecary was backed in 1804 by an ordinance forbidding the grocers and other dealers in the same place to deal, among other things, in spirits of turpentine, purified saltpetre, licorice, muriate of ammonia, and guaiacum wood.

The roll of graduates was kept regularly only since 1770, and numbered, in the one hundred years ending 1870, 1140. Of those graduates who have distinguished themselves must, first and foremost, be named H. C. Oersted (graduated 1797), the discoverer of electro-magnetism; W. C. Zeise (from 1815) is well known for his researches on mercaptan, thialic ether, xanthic acid, and ether, the action of chloride of platinum on alcohol, etc.; E. A. Scharling (from 1828), through his researches on some starches, fats, oleoresins, and balsams, is not entirely unknown as a chemist; Dr. William Neergaard, for many years Vice-President of the New York College of Pharmacy, graduated 1831; Baruch S. Levy, or Lewy (from 1835), became known through his investigations of the atmosphere, wax, etc., and his connection with the mint in Paris, France.

There exist two pharmaceutical journals; one, started in 1844 (*Archiv for Pharmaci og technisk chemi*), appears quarterly, and corresponds to the *American Journal of Pharmacy*; the other one is, properly speaking, a weekly sheet (*Pharmaceutisk Tidende*). Of associations there are two, viz., "The Apothecaries' Association," whose aims and purpose correspond to those of the American Pharmaceutical Association, and the "Pharmaceutical Association," which is more like American local pharmaceutical societies, besides a Pharmaceutical Relief Association.

The Royal Board of Health (Sundheds Collegium) consists of two physicians and two apothecaries.

In speaking of Danish Pharmacy, I must not forget to mention S. M. Trier, who in many respects stands in the same relation to Danish pharmacy as the late Professor Procter stood to American pharmacy. Mr. Trier started, and is still the sole editor of the above-named *Archiv*. He likewise set the different associations on foot, and it is no fault of his if pharmacy in Denmark is not officially recognized as equal with medicine.

CAMPHOR ICE.

The following table, showing various formulæ for the preparation of Camphor Ice, has been supplied to *The Pharmacist*, by Mr. Thomas J. Corell, Graduate in Pharmacy, of Denver, Colorado. The proportions are given in parts by weight.

INGREDIENTS.	1	2	3	4	5	6	7	8	9	10	11	12	13
Ol. Amygd. Exp.	16						8	8					
„ „ Ess.													1
„ Lavand. flor.				$\frac{1}{4}$	$\frac{1}{2}$								
„ Verbenæ flor.						$\frac{1}{4}$							
„ Citronellæ						$\frac{1}{4}$							
„ Ricini		12											
„ Olivæ			12										
„ Rosmarini flor.	$\frac{1}{8}$												
„ Myrciæ Ac.									$\frac{1}{2}$	$\frac{1}{2}$		$\frac{1}{4}$	
Aqua Rosæ	16												
Cera Alba	1	8	3	4	8	16	4		18	18	20	11	20
Cetaceum	1	6	12			8	3	1		8	10		10
Camphora	2	2	6	2	4	4	3	1	8	6	6	5	6
Sevum									36			22	
Sevum Benz.				16	16								
Adeps						24							
Stearin com.										24	24		24
Glycerin			1										

No. 1 is an English formula, and gives a variety of Cold Cream; No. 2 is a formula used by a Cincinnati Pharmacy; No. 3 is a modification of No. 2, by the addition of Glycerin; No. 4 is in use in Philadelphia, Pa.; No. 5 is an English formula; No. 6 is from a Broadway, New York, Pharmacy; No. 7 is of French origin; of No. 8 the pedigree is lost; No. 9 to 13 are formulæ of the writer, and have been extensively used for both wholesale and retail trade, and will give excellent results, with perfectly sweet materials. The perfume is not arbitrary but can be mixed to suit one's taste, but do not consider it economy to use Ol. Mirbane, for it will ruin any of the formulæ.

The manipulation is easy to be understood; in the first and third formulæ it is similar to that of the Cold Cream of the Pharmacopœia; in all the others, the wax is to be melted first, then the cetaceum and lard, then the camphor, and finally, when sufficiently cooled, the essential oils, and then cast into suitable molds.

THE ALKALI ACT AMENDMENT BILL.*

BY J. PATTINSON.

An important measure, especially affecting the interest of manufacturers and the general public in this district, has passed the imperial legislature and become law during the last session of Parliament. I allude to the Alkali Act Amendment Bill. It was quite evident that something more was required to check the escape of deleterious gases than could be enforced by the Alkali Act of 1862. Vegetation in the neighbourhood of chemical works was in many cases being seriously damaged, although the reports of the inspector showed that the amount of muriatic acid escaping was less than the five per cent. on the total amount evolved allowed by the Act. In our own district it is sad to see how, in many places, the hedges and trees are being rapidly destroyed, and it is certain that, unless a change for the better is soon produced, the only trees to be seen on the banks of the Tyne in a few years will be those in the shape of posts to carry the telegraph wires. How different must have been the appearance of Newcastle in 1759, when John Wesley wrote thus of it in his journal:—"I know no place in Great Britain comparable to it in pleasantness!" Dr. R. Angus Smith, the able Government inspector under the Alkali Act, has for many years advocated the amendment of this measure, and it is obvious that the new Act has been chiefly based upon the very numerous experiments and the suggestions made by him given in his valuable annual reports. Those who know the care, intelligence, and caution which always characterize the work and recommendations of this excellent chemist, will not doubt that the alterations, so far as he has been able to control them, are of a practical character, and that whilst due regard is paid to the interests of the populations living in the neighbourhood of chemical works, the restrictions to be imposed to prevent the escape of gases injuriously affecting animal and vegetable life are such as will not unnecessarily interfere with the growth and prosperity of valuable industries.

The first important amendment is to define the term "alkali work," so as to include works in which the treatment of copper ores with common salt is carried on. As large quantities of muriatic acid are evolved in this process, which no doubt in some cases are allowed to escape into the air, the placing of these works under inspection and under the same restriction as alkali works proper, will be attended with benefit.

Another marked improvement in the Act is in restricting the amount of muriatic acid escaping in the chimney gases, or from any part of the works, to one-fifth of a grain per cubic foot of the gases or air leaving the works. The old mode of measuring the percentage of escape in relation to the total amount of muriatic acid evolved is still to be retained in the new Act as a protection in certain cases. By allowing only the escape of a definite amount of muriatic acid per cubic foot of escaping gases a certain state of dilution is insured, and this is a matter of great importance, for it is found that when diluted with air the destructive effects on vegetation are much lessened. The system of measuring per cubic foot is moreover simpler of execution and more easily understood, and allows of the escapes from the body of the works being determined, which could not be done by the other method of measuring by relative percentages.

The most important alteration, however, is that with reference to the escape of other noxious gases than muriatic acid. The noxious gases enumerated which are to be included in the operation of the new Act are, sulphuric acid, sulphurous acid excepting that arising from the combustion of coals, nitric acid or other noxious oxides of nitrogen, sulphuretted hydrogen, and chlorine. In one of his reports Dr. Smith gives an account of some experiments proving that the destructive power of sulphuric acid on vegetation is two or three times greater than that of muriatic acid, and about ten times greater than that of sulphurous acid. He further shows that the gases emanating from the furnaces where copper regulus is calcined contain large quantities of sulphuric acid, and attributes the well-known deleterious effect of the so-called copper smoke to this cause. Mr. Gossage had also pointed out the same thing some time before, and both gentlemen suggest that the copper smoke should be passed through a condenser to wash out the sulphuric acid before being allowed to pass into the air. This suggestion has not yet, I believe, been acted upon in any works. Those amongst us who have been acquainted with Tyneside for some years cannot but have observed how much more rapidly the hedges and trees in the neighbourhood of copper smelting works have been, and are being, destroyed than they were in former years in the neighbourhood of chemical works where this operation was not carried on. Possibly this more rapid destruction may be to some extent owing to the larger scale on which chemical operations are now carried on, but I am strongly inclined to think that it is chiefly owing to the sulphuric acid contained in the copper smoke which at present is allowed to pass unhindered into the air. This state of things will probably now soon be altered. There is no attempt in the new Act to define the amount of other noxious gases than muriatic acid allowed to escape per cubic foot of air. This no doubt will come afterwards, when more is known about the amounts it is possible to condense or render harmless. For the present, it is simply specified that the manufacturer shall use the best practicable means of preventing their discharge into the atmosphere, or of rendering such gases harmless when discharged. The onus of proving that the best practicable means are *not* used, and that an undue amount is being discharged into the atmosphere, rests with the inspector. It is obvious, therefore, that the amount of benefit the public will derive from the amended Act will depend, in a great measure, on the vigilance and care with which the work of inspection is conducted, and on the manner in which its requirements are enforced. Under the judicious management of Dr. Smith we may be sure that the duties of inspection will be carefully and faithfully carried out, and that the new Act will be the means of helping to secure around our manufactories that purity of air which is so essential to the growth of vegetation, and to the health and comfort of the people who are gathered together by the requirements of the manufactures.

One effect of the Act will certainly be to cause more attention to be paid by the manufacturer to the nature and amount of the gases leaving his manufactory by way of his chimneys and otherwise, and the sooner this is done the better it will be for his own gain, in some cases, judging from some of the results of the analysis of waste gases taken from the exits of vitriol chambers given by Dr. Smith. Sulphur acids were escaping, in some cases, equal to sixteen, twenty, and even twenty-seven per cent. of the total sulphuric acid capable of being formed from the sulphur burnt! I am glad to say these cases were not from the Tyne, and I should hope that it is impossible to find such instances of wicked waste in this district.

It appears to be an omission in the new Act that manure works and other works where sulphuric acid is manufactured, together with lead smelting works, and copper smelting works where salt is not decomposed, are not included in its operations. It is difficult to see on what principle these works should be allowed to continue their operations without being placed under the same restrictions as to the escape of noxious gases as alkali

* From a Presidential Address delivered before the Newcastle-upon-Tyne Chemical Society.

works. When more experience, however, has been gained by the inspectors, the present tentative measure will no doubt give way to a more comprehensive one, which shall include in its operation all works liable to evolve deleterious vapours.

I would here like to call the attention of those of our members who are not engaged in the alkali manufacture, and who may therefore not have occasion to read Dr. Smith's reports, to the very great value of these documents. They are not simply a record of the testings of the amount of muriatic acid escaping from the various works, as they might have been had Dr. Smith been content to confine himself strictly to the line of his official duties; but they contain an immense number of analyses showing the amounts of other gases, such as carbonic, sulphurous, sulphuric, and nitric acids, ammonia and various organic substances found in the air near manufactories and in towns, and these are contrasted with the amounts found in country places away from manufactories and habitations; the effect of these substances in the air on the health of the people as well as upon vegetation is attempted to be shown; great number of analyses of rain collected from various parts of Great Britain, showing the impurities which had been washed out of the air, are also given; the work of the same kind done by other chemists on the Continent is duly recorded; in short, these reports form a complete store-house of facts relating to the condition of the air we breathe. The methods of analysis followed are also detailed, and a number of valuable suggestions are scattered throughout their pages. Dr. Smith is doing an immense amount of valuable work tending to throw light upon many of the hidden causes of disease amongst our populations, and his writings are well worth the study of all those interested in this important question. In work of this kind it is absolutely necessary to have great numbers of analyses of air taken from a variety of places and under different circumstances before general conclusions can be drawn. The amount of work it is thus desirable to have is far more than any one man can possibly accomplish or even direct, and I am sure Dr. Smith would be glad to find that other chemists were working in the same field of research. I would advise some of our young chemists to turn their attention to this branch of analysis. They will be amply repaid for any labour and time they may bestow upon it, for the time is fast approaching when the examination of the air of a place will be frequently required to enable us to judge definitely, as Dr. Smith puts it, of its healthiness, without waiting for the evidence in the disease or death of human beings.

HYDRATE OF CHLORAL AS A SOLVENT, AND SUGGESTIONS CONCERNING ITS EMPLOYMENT.*

BY ROBERT F. FAIRTHORNE.

In an article published in October, 1871, in the *American Journal of Pharmacy*, I suggested the use of chloral, when dissolved in oil, as a topical application, and thinking that its power as a solvent might open the way to a greater extent of usefulness, I would draw attention to its value when thus employed in connection with the alkaloids and a few other substances.

A solution consisting of nine parts of hydrate of chloral and three of water I find capable of dissolving the following substances to the extent named:—

One grain of morphia is dissolved by a portion of the liquid containing twelve grains of the hydrate, one grain of veratria by a portion containing five grains, and one grain of atropia by a portion containing twenty grains.

These active principles should be in powder, mixed with the solvent in test-tubes, and heated by means of a water-bath, with occasional agitation.

The solutions thus made are in a convenient form for employment, either alone or when mixed with oils, ointment, or with glycerin. Camphor, too, is freely dissolved by them, and in some cases can be added to them with advantage.

Glycerin I find to be a convenient agent for forming solutions with chloral and the above-named substances, and the following will be found, when properly combined, to produce permanent and elegant preparations, viz.:—

Chloral Glycerite of Morphia.

℞ Morphia (Powd.) . . . 5 grains.
Chloral hydrate . . . 1 drachm.
Glycerin . . . . half a fluid ounce.
M. Sec. art.

Chloral Glycerite of Veratria.

℞ Veratria . . . . 5 grains.
Chloral hydrate . . . 1 drachm.
Glycerin . . . . half a fluid ounce.
M. Sec. art.

Ointment of Chloral and Veratria.

(Corresponding in strength to the Ung. Veratriæ, U. S. P.).

℞ Veratria . . . . 10 grains.
Chloral hydrate . . . ʒi.
Water . . . . 6 drops.
Lard Ointment . . . half an ounce.
M. Sec. art.

Chloral Glycerite of Morphia and Camphor.

℞ Morphia . . . . 5 grains.
Chloral . . . .
Camphor . . . . . each 1 drachm.
Glycerin . . . . half a fluid ounce.
M.

Lotion of Chloral and Iodine.

℞ Iodine . . . . 20 grains.
Iodide of Potassium . . 6 grains.
Glycerin . . . . 1 fluidounce.
Chloral hydrate . . . 2 drachms.
M. Sec. art.

Chloral can also be combined with collodion, in which it dissolves after the addition of a few drops of alcohol.

* From the *American Journal of Pharmacy* for December.

THE MOVEMENT OF WATER IN PLANTS.

Dr. W. R. M'Nab, of Dublin, has been making a further series of experiments on the amount of transpiration from the leaves of plants and on the ascent of sap through the stem, with the following results, the plants experimented on being the cherry-laurel (*Prunus laurocerasus*), privet, and elm:—1. That under favourable circumstances a rate of ascent of 40 inches in the hour can be obtained. 2. That, contrary to the generally received opinion, direct experiment has shown that the upward rapid current of water does not cease in the evening. 3. That checking the transpiration for a short time by placing the branch in darkness does not materially retard the rapid current of water. 4. That the removal of the cortical tissues does not impede the rapid current in the stem, which moves only through the wood (*xylem*) portion of the fibro-vascular bundles. 5. That a well-marked rapid flow of fluid will take place in a stem after the removal of the leaves. 6. That fluid will rapidly flow downwards as well as upwards in the wood (*xylem*) portion of the fibro-vascular bundles, as seen in a branch in which lithium citrate was applied at the top. 7. That pressure of mercury does not exert any very marked influence on the rapidity of flow, in the one experiment made with a pressure of 110·53 grammes of mercury. Dr. M'Nab points out with great force the disadvantage under which research in vegetable physiology labours in this country, from the fact that neither at Dublin nor elsewhere is there a physiological laboratory in connection with a botanical garden, a conjunction almost necessary for the carrying out of original research.

MEDICAL AND PHARMACEUTICAL DUTIES.*

Under the above title the last number of the *Lancet* contains the following remarks *à propos* of a subject recently discussed in our editorial columns.

"Some of our contemporaries have been exercising themselves in defining the line of demarcation which divides or should divide the druggist from the doctor. It is unsatisfactory that there should be any need to make clear a distinction which should be so obvious. A medical man is one who is supposed to be possessed of special knowledge of the processes of disease and of the methods by which they may be controlled. A druggist is one who deals commercially in some of the articles by which disease is controlled. The doctor's essential wares are opinion and advice; the druggist's wares are drugs. It is lamentable to have to admit that there are some doctors who cannot get a livelihood, or who think they cannot, without supplementing their proper wares—opinion and advice—with a perfectly heterogeneous class of articles, such as tooth-brushes, enema syringes, patent medicines, etc. There is a still larger proportion of druggists who overstep the line, and give themselves out as dispensing not drugs only, but opinion and advice on subjects and cases in regard to which they can know no more than the persons for whom they prescribe. We appeal to druggists themselves if this be not so. We are not speaking now of trivial ailments, like that of a man who has a slight cold, or who has been dining out over night and wants a little corrective, but of graver conditions which druggists prescribe for often too long for the patient's welfare or their own reputation. We should gladly see all respectable medical men wipe their hands completely of the sale of drugs and other articles, which constitutes the legitimate occupation of druggists. We go further, and say that we should like to see every medical man relieved of the drudgery of dispensing his own drugs from his own premises. But at present this seems impracticable, chiefly owing to the costliness of dispensing by druggists. If the Pharmaceutical Society would devise a means of supplying the community with good drugs at a reasonable cost, and would discourage the assumption of medical functions by its members, then there would be a prospect of medical dispensing being bodily handed over to druggists — a consummation devoutly to be wished in the interest of druggists, practitioners, and the public."

THE SOUTH LONDON SCHOOL OF PHARMACY.

The annual dinner of the students of this institution was held on Friday evening, Dec. 18th, at the Horns Assembly Rooms, Kennington, under the presidency of Dr. Muter, Mr. Baxter occupying the vice chair.

The cloth having been removed, and the usual loyal and patriotic toasts having been given—

The chairman in proposing the toast of the evening, "Success to the South London School of Pharmacy," said, he would not enter into any of the points that had been freely discussed during the past session with regard to other schools, but he could not do better than refer to the encouraging spread of pharmaceutical education in the country. Pharmaceutical education as it now existed was a great fact, of which those present were living witnesses, being able to go into business, and understanding the nature and properties of the things they dealt in. There were, he hoped, now no assistants who did not understand the difference between sulphate of zinc and Epsom salts. He thought the examinations had now been brought to such a point that they were a thorough test of a man's practical knowledge, that they were now conducted in a fair and proper manner at Bloomsbury Square, and that the best men only passed. It was a test that could only be passed by thoroughly practical men, and it was to make such men that the South London School was established. Not only had there been a great improvement in the standard of education, and in the practical manner of conducting the examinations, but young men generally had now a desire to get a good foundation of knowledge before presenting themselves. They took a longer time to do it in, but were more sure of their future prospects. He was not one of those who said that a man who made the examination the end of his studies was to be altogether despised, and for this reason, they were not all blessed, to put it mildly, with too much of the filthy lucre. Many students had to be in the shop all day, at a very small salary, and men in such a position who studied attentively and attained their object, that of getting into business, were, in his opinion, deserving of praise. It was another thing with men who had money and time at command; they did those around them great injury if they stopped short in their studies. They were the men who ought to go on and not be satisfied until they got more than a qualification for their examinations. What was one man's meat was another man's poison; and the man who had money and time at command was the man who continued studying and never tired. The man who had not the means might have the same wish for study, and he was to be commended if out of his hard earnings and in hours snatched after closing time, he succeeded in passing his examination and establishing a business. Both classes were equally to be praised. The examinations as they now stood were amply sufficient to test a man's qualifications, and he thought they were sufficiently strict, and they might rest a while before any alterations were made with regard to the recognition of schools. The South London School was in such a state that it could not be ignored if any schools were recognised. There were cases where young men could not attend the lectures in the daytime, and for such evening schools would be good things; but when evening lectures were established at that school only two students entered, one of whom never paid the fee. The examinations in chemistry at Bloomsbury Square were now very rigorous, and men must now be well up both in theory and practice in order to pass; but as they did pass it showed that education was improving. In conclusion, he hoped the new regulations would have a fair trial before any alteration was attempted.

The toast having been drunk the Vice-Chairman gave "the Successful Candidates," coupling with it the name of Mr. Knight.

Mr. Knight, in response, said he must say the examiners at Bloomsbury Square treated him with great kindness, sympathy, and consideration, and the examination was thoroughly practical.

The "Unsuccessful Candidates," "The Press," and other toasts having been proposed and responded to,

The Chairman, in proposing "The Medical Profession," said a good deal of discussion had lately arisen as to the relative merits of doctors and chemists. He considered the limit of the profession was that the education of a medical man only fitted him to go to the bedside of the patient, diagnose the case and write the prescription, whilst the education of a chemist fitted him to dispense the prescription, and put it up in the most attractive and palatable form. Pharmaceutical chemists were now allowed to compete for the appointment of public analysts, and he hoped all young men would qualify themselves for such a position. He begged to couple with the toast the name of Dr. Abbott Smith.

Dr. Abbott Smith, in responding, said he thoroughly endorsed all that the Chairman had said as to keeping the two branches of the profession distinct. Fifty years ago they were distinct, and he hoped they would be so again.

Several other toasts were given in the course of the evening, and the proceedings were also enlivened by various songs and choruses.

Mr. Hayho ably acted as toast-master.

---

* From *The Lancet*, December 19.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 26, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed* "*Pharm. Journ.*"

MEDICAL AND PHARMACEUTICAL DUTIES.

RATHER grudgingly, but apparently a little afraid of being left behind by the healthy advance of medical opinion respecting the line of demarcation which divides, or should divide, the druggist from the doctor, the *Lancet*, as will be seen by a reference to p. 508, at last virtually admits the justice of the views so frequently urged in these columns. We are content to accept this admission without even contesting the assumption put forth that druggists are the most prone to overstep this line, however much we may be inclined to doubt its correctness, because we feel certain that the remedy of the acknowledged evil lies mainly with the medical profession.

We note, however, an incidental omission, because it is characteristic, and explains a certain amount of obtuseness, which is not characteristic of our contemporary. The *Lancet* pragmatically says, "The doctor's essential wares are opinion and advice; the druggist's wares are drugs." And why are not "opinion and advice" to be included amongst the druggist's wares. We do not mean of that kind which is known under the name of "counter prescribing;" but opinion and advice upon the subject in which they are especially educated, the scientific preparation of medicines for administration. If the pharmacist's special knowledge and skill are to be appraised as valueless, or as a kind of makeweight to be thrown in with the drugs, what mean the demands for the higher education of pharmacists and the stringent examinations they have to undergo? Or are the examinations supposed only to guarantee that the pharmacist has acquired an amount of pharmaceutical knowledge equal to that the medical practitioner possesses intuitively? If it were not for the descriptive title of our contemporary's article, which is the same as we have adopted, it might have been supposed that the definition was an attempt to limit the functions of the herb doctor or drysalter.

The *Lancet* is now panting for the time when every medical man shall be relieved of the drudgery of dispensing his own medicines from his own premises; but its faith is obscured, chiefly owing to an assumed costliness of dispensing by druggists. It however looks to the Pharmaceutical Society to act as the *Deus ex machinâ* in this emergency, by devising a means of supplying the community with good drugs at a reasonable cost. This would appear to indicate that the *Lancet* believes such a desideratum to exist; but we are inclined to class such a belief as equally an assumption with that previously indicated. Indeed, were the Pharmaceutical Society to undertake such a foolish and impracticable task as the regulation of the charges for drugs under all conditions and circumstances, it is very probable that the *Lancet* would be among the first to censure the attempt as being beyond its functions. Therefore, notwithstanding the tempting bait of medical dispensing being bodily handed over to the druggists, which our contemporary thinks is "a consummation devoutly to be wished in the interest of druggists, practitioners, and the public," we cannot hold out any hope of the medical profession being allowed to shirk its share of the work in that way. Meanwhile, we would ask the *Lancet* to make a choice between the two horns of a dilemma. Is there anything inherent to the calling of a chemist and druggist which removes him from the ordinary rules of competition that compel all other tradesmen to supply their "wares" at a moderately remunerative price? Or does the medical practitioner who now does his own dispensing supply his medicines at a rate which is not remunerative; in fact, throw them in as a makeweight with his medical advice?

We are glad to notice that the subject also shows evidence of progress in the United States. The joint committee, consisting of delegates from the Society of Physicians and Surgeons, the Medical Society, and the College of Pharmacy of Chicago, the appointment of which was mentioned last month, has now presented its report. It condemns the exercise by physicians in any way of an interested preference for particular pharmacists; the practice of any branch of medicine by pharmacists; the use by physicians of prescription blanks bearing the name of a pharmacist; and the prescribing of medicines by adding to their titles that of a proprietor or patentee. The Chicago College of Pharmacy has passed resolutions endorsing the report, and also a further one condemning the practice of physicians who write prescriptions in a manner and form unintelligible to educated pharmacists.

OPIUM IN CHINA.

GOVERNMENT interdicts and proclamations notwithstanding, the poppy continues to be cultivated with increased activity in China. Interfering tax-gatherers and subordinate officials are "squared" by bribes, the exaction of which forms quite a revenue to the venal bureaucracy of the Flowery Land. Indian opium, however, is consumed in nearly as large quantities as ever—the native drug being only used for mixing with the former. Nor is this to be wondered at. Indian opium is prized for its freedom from the bitter and disagreeable flavour characteristic f its Chinese counterpart, which has also the reputation of causing eruptions of the skin, small boils, and ulcers, and even dysentery if taken *per se.* Quality, according to the reports of the British Consuls at Newchang, Hankow, and Kewkiang, is the pivot on which the whole future of the opium trade with China turns; and if it can be shown that the inferiority of the Chinese drug is neither absolute nor inherent—due neither to soil nor climate, but to want of skill on the part of producers, or to adulteration on the part of dealers—then, with improved cultivation and greater honesty, it may prove a serious rival to the Indian article.

Smuggling opium is more prevalent than ever. According to Mr. Hughes, the consul at Hankow, last year was exceptionally prolific in smuggling operations, "the triennial examinations for the degree of Master of Arts having attracted great numbers of candidates who are said to have carried considerable quantities of opium in their baggage which, in such cases, is exempt from Customs' examination." So adroit, indeed, are the Chinese as smugglers, that the returns of the import of opium are quite illusory.

The physiological effects of opium smoking—so long at least as the indulgence is moderate—are much less baneful than have hitherto been represented. Mr. W. C. King, Vice-Consul at Kewkiang, reports that when on a tour on the Upper Yangtoze, and in Szechuen, he saw no physical or moral deterioration among the junk sailors and others, who smoked with impunity. They seemed *bien conservês* and had prodigious appetites, while their work was very hard, lasting from dawn to dark with scarce an interval, and requiring them to take constant headers into the stream at all hours and in places highly perilous from under-currents. "The two persons," he says, "most addicted to smoking were the pilot and the cook. On the incessant watchfulness and steady nerve of the former the safety of the junk and all on board frequently depended, and the second worked hard from three in the morning till ten at night, and often longer, and seemed independent of rest and sleep." The cook, it appears, had a self-manufactured conserve of sugar and opium, which he chewed during the day—when, of course, he could not smoke. But at night he lit up and puffed like his neighbours. From these and similar observations Mr. Consul King contends that opium smoking or opium chewing, while practised in moderation as a sedative or a stimulant, is quite compatible with health, long life, and full physical and mental activity.

THE SUMBUL PLANT.

The *Gardeners' Chronicle* quotes a statement made by Mr. Wobst, of the Moscow Botanic Garden, to the effect that he has this year succeeded for the first time in raising the Sumbul plant (*Euryangium Sumbul,* Kauff.) from seed. He sowed the seeds in the autumn of last year in a dung bed, and covered them up later with snow and lights; they freely germinated in the spring. One notable characteristic is the manner of the development of the first leaves, which appear below the cotyledons, a peculiarity not infrequent in *Anagallis arvensis,* several species of *Euphorbia, Antirrhinum,* etc., and previously observed in some species of Umbelliferae. Mr. Wobst has found that the Sumbul invariably dies after once flowering; of all the plants that have flowered with him not one has thrown up a second flower.

GURGUN OIL AS A CURE FOR LEPROSY.

According to the *Homeward Mail* recent reports from the Andamans have afforded such additional evidence of the value of Gurgun Oil as a cure of leprosy, that the Marquis of Salisbury is very desirous of the widest publicity being given throughout India to this mode of treatment, as originally recommended by Dr. Dougall. The medical agencies at the disposal of the Government are to be employed to assist in the promotion of this object, and notice is given that the principal medical storekeeper at Calcutta has made arrangements for obtaining a large supply of the oil from the Andamans for distribution to the different hospitals and dispensaries upon application. The President in Council invites the co-operation of all the local governments and administrations towards the extension of the use of this medicine in cases of leprosy, and requests that careful reports on the results may be submitted at the end of the year for the information of the Government of India.

THE DANGERS OF CHLOROFORM.

Under the above title the *Scientific American* records the death of a patient in the dental chair, whilst under the influence of chloroform, as having taken place at Boston. The medical evidence at the inquest was to the effect that the lungs of the deceased were affected with phthisis, and unable to throw off the influence of the chloroform. The jury, however, returned a verdict that the death was due directly to the inhalation of the chloroform, and added a rider recommending legislation to prohibit the administration of chloroform, as in their opinion, in the present imperfect state of knowledge respecting its action, its use as an anæsthetic is quite unjustifiable. The *Scientific American* deprecates special legislation against the use of chloroform as an anæsthetic, which it considers to be unnecessary, because the growing tendency of the medical profession in the United States is to use either pure sulphuric ether or a mixture of chloroform, ether, and alcohol, whilst the employment of nitrous oxide in dentistry is greatly extending.

QUACKERY FINDING ITS LEVEL.

The introduction of a Bill into the Texan Legislature to regulate the practice of medicine in that State, has afforded, according to the *Druggists' Circular,* an opportunity for the Texas Medical Society to bring forward a rather eccentric amendment. This amendment provides that any person, who is not a citizen of the State, who shall advertise therein his ability to cure disease or perform surgical operations, shall pay the same tax as is paid by persons exhibiting a circus performance or menagerie, and shall be liable to the same penalties if he commence his public performances before paying the tax.

ROYAL INSTITUTION ARRANGEMENTS FOR 1874-5.

We have received from the Secretary of the Royal Institution the programme for the coming session at that institution. The following are mentioned as the probable arrangements for the Friday evening meetings before Easter, 1875:—

Jan. 15th. Professor Tyndall, D.C.L., LL.D., F.R.S.:—"Some Acoustical Problems."

Jan. 22nd. Sir John Lubbock, Bart., M.P., F.R.S., M.R.I.:—"Wild Flowers and Insects."

Jan. 29th. Professor Huxley, LL.D., F.R.S.:—"Recent Work of the 'Challenger' Expedition, and its Bearing on Geological Problems."

Feb. 5th. James Dewar, Esq., F.R.S.E.:—"Physiological Action of Light."

Feb. 12th. W. R. Greg, Esq.

Feb. 19th. Professor Frankland, F.R.S., M.R.I.:—"Climate."

Feb. 26th. W. R. S. Ralston, Esq., M.A.:—"Popular Tales: their Origin and Meaning."

March 5th. The Lord Rayleigh, M.A., F.R.S., M.R.I.

March 12th. Professor Abel, F.R.S.:—"Accidental Explosions."

March 19th. Richard Liebreich, M.D., M.R.C.S., M.R.I.:—"The Real and Ideal in Portraiture."

The following are the Lecture arrangements for 1874-75:—

John Hall Gladstone, Esq., Ph.D., F.R.S.—Six Christmas lectures (adapted to a juvenile auditory), on the "Voltaic Battery," on Dec. 29 (Tuesday), 31, 1874; Jan. 2, 5, 7, 9, 1875.

E. Ray Lankester, Esq., M.A.—Six lectures on the "Pedigree of the Animal Kingdom." On Tuesdays, Jan. 12 to Feb. 16.

Alfred H. Garrod, Esq.—Four lectures on "Animal Locomotion: including Locomotion on Land, in the Air, and in Water." On Tuesdays, Feb. 23; March 2, 9, 16.

Professor P. M. Duncan, F.R.S.—Three lectures on the "Grander Phænomena of Physical Geography." On Thursdays, Jan. 14 to 28.

Professor Tyndall, D.C.L., LL.D., F.R.S.—Seven lectures on "Subjects connected with Electricity." On Thursdays, Feb. 4 to March 18.

Edward Dannreuther, Esq.—Two lectures on "Mozart and Beethoven: with Pianoforte Illustrations." On Saturdays, Jan. 16 and 23.

J. T. Wood, Esq.—Four lectures on the "Discovery of the Temple of Diana, and other Results of the Government Excavations at Ephesus." On Saturdays, Jan. 30, Feb. 6, 13, and 20.

Professor W. K. Clifford, M.A., F.R.S.—Four lectures on the "General Features of the History of Science." On Saturdays, Feb. 27 to March 20.

LEGACY TO THE BENEVOLENT FUND.

The Secretary has received from the executors of the late Mr. Henry Tertian Sissmore, of Cranbrook, a legacy to the Benevolent Fund of £10. Mr. Sissmore became a Chemist and Druggist Member of the Pharmaceutical Society in 1873.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 16th, 17th, and 18th, 1874.

Present on the 16th—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

17th—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

18th—Messrs. Allchin, Benger, Bottle, Carteighe, Corder, Cracknell, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

Dr. Greenhow was present on the 16th and 18th on behalf of the Privy Council.

MAJOR EXAMINATION.

Ten Candidates were examined. *Four* failed. The following *six* passed and were declared qualified to be registered as Pharmaceutical Chemists:—

Knight, Benjamin..................Yeovil.
Cox, William Dennis ....Grantham.
Stacey, Henry George ....London.
Shapley, Charles ....Torquay.
Flint, Charles Bruce...............Glasgow.
Newton, Thornton Albert C. ...Devonport.

MINOR EXAMINATION.

Sixty-four candidates were examined. *Forty-eight* failed. The following *sixteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

	Thomas, Harry Alma	London.
	Izod, James Hickman	Sittingbourne.
	Green, Charles Henry	Hastings.
Equal.	Cook, Robert, jun.	Great Grimsby.
Equal.	Sandwith, William Henry	Scarborough.
	Jones, William	Oswestry.
	Handford, Joseph John	Great Torrington.
	Kennett, John Nash	Havant.
	Phillips, Frank Leslie	Birmingham.
	Walker, Benjamin	Sheffield.
Equal.	Maxwell, James Ashworth	Altrincham.
Equal.	Stephens, George Thomas	Hereford.
Equal.	Barker, Charles Dexter	Birmingham.
Equal.	Fletcher, Howard Bennett	Leicester.
Equal.	Westwood, Amos	Stone.
	Litchfield, John	Longton.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The following six certificates were received in lieu of this examination:—

Certificate of the College of Preceptors.

Phillips, James Arthur............Penge.

Certificate of the University of Cambridge.

Humphries, Charles Josiah......Ipswich.

Certificate of the University of Durham.

Longstaff, William Luther ......Sunderland.

Certificate of the University of London.

Mountford, Mountford Wyche...Matlock Bridge.

Certificates of the University of Oxford.

Oldham, William ....Peterborough.
Skinner, Robert......................Liverpool.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Carbon and certain Compounds of Carbon.*

BY PROFESSOR BARFF.

(*Concluded from page* 497.)

Lecture VI.

A well-known illustration of conductive power is to put some common wire gauze over a flame; no flame passes through it—gas passes through, but not flame. The wire gauze conducts the heat away, so that there is not sufficient heat above to ignite the gas which passes through it. That is the principle on which the action of the Davy safety lamp depends.

Another interesting experiment is to put a coil of wire over the candle, and simply by its conducting power it will take away so much heat that the candle cannot go on burning; combustion will cease, that is to say, the candle gas cannot go on being formed, and, even if it were formed, it would not be at a sufficiently high temperature to unite with the oxygen of the air. If the wire be made hot, and put over the candle flame again, then the candle will go on burning, because, being hot, it cannot conduct the heat away from the burning candle.

To pass on to another method by which heat passes from one body to another, namely, by radiation. Take a metal cube filled with boiling water and coated on one side with lamp-black, and on the other polished. The heat will leave the cube more rapidly from the side coated with lamp black than from the side which is polished metal. We therefore say that rough and blackened surfaces are better radiators of heat than bright, polished, metallic surfaces.

The most perfect idea of a heating apparatus is one that will retain its heat for a length of time, and which will give out its heat gradually. The heat from it is then distributed throughout the whole of the chamber. If we have a chimney up which a quantity of heat escapes impelled by the draught in the room, necessary to promote and keep up the combustion of the substances burning in the grate, we are losing a portion of the heat. Some grates, called American stoves, give promise, and deserve a trial. The principle on which they are constructed is good, and a fair amount of heat is sent out into the room, and as little as possible up the chimney. But even they are far from perfect. What we want to see, and what inventors ought to turn their minds to produce, is this—a stove, the products of combustion from which shall, before they leave the chamber, become cold or nearly so. Now, such a stove can be made, and can be made without interfering with our English liking for a bright cheerful fire. There is no difficulty whatever in conducting the products of combustion from a fire-place through an apparatus of winding tubes, provided you ensure sufficient access of oxygen to the fire to keep up the burning. That is all that is requisite. "In our present fire-places," said the lecturer, "we may have the stove standing with its front exposed where we can see all the coal. But on the top of it have a plate which can be put down and taken off at pleasure, then let the products of combustion come from the front near the bottom of the fire, for in that way what usually now escape as unburnt gases will be burnt in their progress through the fire; then lead the product through pipes, arranged in a picturesque way if you like, covered by an iron grating, but have them so arranged that they will give out the heat resulting from the hot products of combustion to the air, which will pass through the tubes enclosing the flue tubes, through which these products of combustion pass, and I believe in that way for the purpose of heating rooms, you will be able to get all the heat into the room that could possibly be got from the fire."

* Abstract of a course of Cantor Lectures, delivered before the Society of Arts.

Another subject intimately connected with radiation is the absorption of heat. Take two tin plates; one with a bright surface, while the surface of the other is blackened. Two balls are fixed by means of wax to these plates, and one put on each side of a gas burner. One of these balls will fall before the other, and that will show that the plate to which it is attached has got hotter than the other. The ball attached to the blackened plate will fall first. Black is a good absorber of heat, as well as a good radiator. If a black substance radiate heat, it is quite certain that we must not blacken those vessels which we desire should contain water, or any other substance, at a high temperature for a length of time. If we want to retain the heat as long as we can we must use polished surfaces. For example, a bright silver teapot will keep tea hot longer than a black one; on the other hand, suppose we want to keep water hot in a teapot and we put it on the hob, then a black teapot is better than a polished one, because the black teapot will absorb the heat from the fire, whereas the bright metal teapot will reflect back the heat and will not absorb it readily.

The bearing which this radiation of heat has upon all apparatus which are used for cooking or heating is evident. To blacken a fire-grate is to cause it to absorb heat, and if the thing blacked be metal, the heat is absorbed, and the metal conducts the heat away into the brick work of the chimney. If you have a fire-clay back to your grate, and if, from a wish to make the fire-stove look neater and cleaner, you blacken that, you are actually, in fact, defeating in part the object for which you have the fire-clay back. If you have a fire-clay back, leave it the colour of the fire-clay, and if you have a metal back polish it. There are certain grates which were made some time ago, the backs of which were like that of a mirror, a hole being in the back to let the products of combustion pass up the chimney. If you stand in a large room, facing the fire, with such a grate, the heat is oppressive. Such a stove or fire-place is not handsome to begin with, and it is very unpleasant to sit directly in the focus of such a mirror, and to have the heat directly cast upon you. But at all events a very considerable portion of the heat which otherwise would be conducted away by the iron, is reflected by the polished metal. If you do have metal at the back of iron fire-places keep it polished, but it is much better to have fire-clay.

Whenever you want to prevent the escape of heat from anything, whether it be a fire-place fixed in a room or from a cooking apparatus, use fire-clay for the outside coating.

There are substances which will not allow heat to pass freely through them, of which class of substances glass is a very fair representative. These substances are spoken of as being *adiathermanous*. Glass is one of those which is not diathermanous; that is, it will not allow heat rays to pass freely through it. Therefore, if we want to shut off heat from any part of a room, we cannot do better than put a plate of glass between the source of heat and the thing we want to keep cool, for the heat will not pass readily through it. There are certain substances which allow heat rays to pass through very readily, of which rock salt is a good example. It will allow about 90 per cent. of the heat to pass through, whereas glass will only allow a mere trifle. But we know that glass in time will get hot, if it is near the source of heat, and then it will radiate, so that it does not do, if we want to use glass to keep off heat from any object, to allow it to get hot. Glass is also transparent to rays of heat of a high intensity, but it is almost opaque to rays of heat of a low intensity. For instance, it is transparent to the rays of the sun. You know that the sun's rays pass through the glass of a greenhouse and make it hot, but when the heat has passed through the glass, that heat is reflected back by the ground and by the walls of the greenhouse, and then becomes heat of low intensity; and that heat is not able to pass through the glass, and this is how it is that the sun's rays heat a greenhouse. Heat, then, of high intensity can pass through glass readily, but not heat of low intensity.

Now, then, to pass on to what is perhaps the most interesting portion of this subject—its practical applications, though we have already had many practical applications of those principles which have been enunciated. As general principles on which all fire-places for warming rooms should be constructed, two things have to be remembered. There is a heating material which is only able, by its combustion, to give out a certain amount of heat, and care must be taken by some means to isolate that from any substance which will conduct away the heat. One thing we must have—we must have a cheerful-looking fire; and another thing we should aim at, and that is to lose no heat, but to get all the heat out of the substances we burn. We cannot create heat. When we put chalk or other substances with coal, we perhaps produce a beneficial result, because the chalk or similar substances acts as a store house of heat, retains it for a while and gives it out slowly. But it is simply impossible that chalk, by its decomposition and the evolution from it of carbonic acid, which carbonic acid in the fire is said to be converted into carbonic oxide by the carbon of the fire, can produce heat; it is simply impossible that more heat can be got out of the coal by this operation. For the amount of heat which is required to drive off the carbonic acid from that chalk is lost as heat, it is doing chemical work and therefore ceases to act as heat, and it only becomes heat again in exactly the same quantity when that carbonic oxide unites with the oxygen of the air to form carbonic acid. A certain weight of carbon will unite with a certain weight of oxygen, and in so doing will give out, say, 25,000 thermal units. The product of the decomposition is carbonic oxide. Now, that carbonic oxide unites again with more oxygen and forms carbonic acid, and here we have 69 thermal units given out in this second union between the oxygen and the carbon—why that is need not be explained now, though there are many explanations of it which are extremely rational. If, then, carbonic acid is driven off from chalk—and those who have ever seen a lime-kiln burning know what a high temperature is required to perform the operation—the heat there absorbed is lost as heat. Use the chalk and use the fire-clay as store-houses for the heat, and to moderate the rapidity with which it is given out, and these are most valuable properties for any apparatus or furnace that is used for warming rooms.

Many cooks think that they are doing their work better by boiling things rapidly and quickly. But it is not so. Water boils at 100° C., or 212° F., but you do not require that heat or anything approaching it to cook meat thoroughly and properly. A series of experiments have been performed in the laboratory at University College. Albumen, or white of egg, subjected to a temperature of 58° to 60° C., or about 140° F., was coagulated on the outside of the vessel. Now, when the albumen or white of egg was exposed to a temperature of 65° C., the albumen was shortly coagulated all through its mass—that is to say, if we had been speaking of an egg we should say it was perfectly done, and the white was well set. This would take place at about 150° F., very much below the boiling point of water. Other experiments were performed on a slice of meat a quarter of an inch thick; a slice of meat was exposed in an air bath to a temperature of 65° C., for an hour, and it was not quite cooked through; but when it was exposed to a temperature of 88° C. it was thoroughly cooked, and not only thoroughly cooked, but the outside of it was thoroughly browned, and this took place at a temperature considerably below the temperature of boiling water.

To those who have not been accustomed to consider these matters, this must let a flood of light into their minds. What is the use of exposing our meat to the high temperature to which we do expose it, and of so wasting our fuel? The meat continually gets charred outside, whilst it is raw in the centre, because the coagulated albumen on the outside acts as a non-conductor of heat to the underdone meat in the inside, and the heat cannot pass through to that which has to be cooked. The same happens when meat is put into boiling hot water, and kept boiling as fast as possible, the albumen on the outside gets coagulated, and the heat is not able to penetrate into the centre, and it does not get properly done.

To give you an idea of what can be done, the Lecturer exhibited a small apparatus, which he described as follows: "Here is a simple gas-burner over which a flask of water is placed, and steam is being generated and is passing into a zinc vessel containing some water in which is placed a piece of meat, the whole being enclosed in a wood box. Here is a thermometer to show the temperature. It is now 80° C. It is not a large piece of meat, but I have not the least doubt it will be cooked before we leave the room this evening. The meat was first put into cold water, the steam was then introduced, and has heated the water up to 80°. This steam keeps going into the water, and supposing I had another box here, and another one here with sufficient tubes, the steam would pass into all these boxes, and warm the water in each box contained in the cooking vessel, and thus the meat and potatoes, and various things, might all be cooked from one vessel generating steam. How is it, then, that the heat would not be lost here? The temperature is 80° C. inside this box, but it is cold outside. This is a box simply containing a quantity of sawdust, which is placed around the metal vessel in the centre, into which the steam passes. You have only then to have a series of boxes, and you can cook your dinner very economically. But some persons may say we cannot always be living on boiled and stewed meat, we must have it sometimes roasted. That is perfectly true. But all you have to do is to adopt the principle of Captain Warren's cooking apparatus, which is a most excellent one. Have a dry vessel inside, without any water in it, so arranged that the steam can play round between the two vessels. Then the steam will warm the inner vessel, and your meat will thus be cooked without water, but it will not be browned." He then explained a rough diagram of the sort of apparatus he would recommend. "In the centre is a Bunsen gas burner, burning about 9½ to 10 cubic feet of gas per hour; above it there are lumps of fire-clay, and around it is a vessel containing water, which is a bad conductor of heat. To insure that no heat is lost, it is jacketed and filled in round about with powdered charcoal, or some non-conductor. The water boils, the steam passes off into this vessel on the right hand side, and cooks something there, and also passes off into the vessel on the left hand side, and cooks something in it. Now, suppose for a moment that we have no water in this one on the right hand side, but that we have a vessel jacketed so that the steam may pass round outside it, and your meat is put in that, then the meat will undergo the first process of roasting. The heat also heats these fire-clay lumps above, and if you want anything fried you can fry it above there, or you can put it on a gridiron, and can grill it, or you can put on this cap. That is a little apparatus round which the heat will travel and come out at the top, and so at the other side. The heat has been doing all this work in cooking these various substances, and we must not mind at present, with our limited knowledge, if a little escapes at the top, but I think we might even utilize it. Here we have a dry heat —a temperature sufficiently high to brown the meat, because it is much higher than the 90° C., which was shown to frizzle the meat and brown it outside, so that you may take out the meat from the jacketed vessel where it has been partially cooked, and then put it into this chamber where it can be browned, and thus you can with such an apparatus easily cook, I believe, a dinner for ten or twelve people, because here on the top you can fry your cutlets or anything else before the browning takes place." Such an apparatus could be worked at a very small cost.

Next, as to the application of these principles to lighting. Messrs. Dietz and Co.'s lamps are flat-wicked lamps. The air is allowed to pass in through slits in the side, and is so arranged that it is claimed to produce the greatest amount of light possible for the size of the wick, and the quantity of oil burnt. It is stated that a wick three-eighths of an inch gives the light of six candles, with a consumption of half an ounce an hour,

$\frac{5}{8}$ inch wick . .	12 candles . .	$1\frac{1}{8}$ oz.
$\frac{3}{4}$ " . .	14 " . .	$1\frac{1}{3}$ "
1 " . .	20 " . .	$1\frac{3}{4}$ "
$1\frac{1}{2}$ " . .	25 " . .	2 "

Messrs. Silber's lamp has a different arrangement. Mr. Silber admits air in two ways to the wick. His wicks are circular, and the air comes up through two places. The wicks are very porous; a certain quantity of oil rises, and a small quantity of it is vaporized. If there be the proper adjustment of the draught to the consumption of the oil, a current of air meets the vaporized oil, and it will burn, if the thing be properly managed, at a certain distance above the wick. That is what Mr. Silber says is managed in his lamps when they are properly arranged, so that, provided the lamp be properly burnt, you do not get any charring of the wick. There is a ship's lamp, in which colza oil is burnt without a glass. Inside that lamp is a dome, which comes down upon the oil-chamber, which can be drawn easily out of the lamp. At the back of the oil-chamber there is a slit, through which the air passes to the wick, so that the whole of the air that is used for the combustion of the oil passes in from the top round the back and underneath into the wick; no air whatsoever getting into the lamp by any other access. The consequence is that a light is obtained which is perfectly steady, and which can be waved or moved about, as in the case of a vessel lying at anchor, without any danger whatever. There is another point in connection with Mr. Silber's invention which is of great scientific interest—namely, the way in which he prevents the draught or anything interfering with the flame in such lamps as this. No gale of wind will cause the flame to flicker, because no air whatever has access to it except through the proper channel. There must be in a lamp like this such an adjustment of air as that you get the most perfect combustion consistent with luminosity, but we have a lamp also that no gust of wind can affect. At the top there is a cone, and the heat products from the lamp pass round the sides, and the air can play against it, but cannot enter against those heated currents, and in that way all flickering of the light is prevented.

The lecturer concluded by describing a gas burner in which these principles are applied, the admission of air being regulated in a somewhat similar manner to that in the ship's lantern. These gas burners, however, are not yet brought into the market, Mr. Silber having something yet to do to perfect them.

PHILADELPHIA COLLEGE OF PHARMACY.

The second pharmaceutical meeting of the present session of the above College was held on November 17, Professor Remington presided.

Specimens illustrating the various stages of the process of preparing "compressed camphor" were exhibited by Professor Maisch. Compressed camphor is prepared from Japanese crude camphor, the colour of which is grey to pinkish-white, layers of various degrees of purity being often found in the same tub. Japanese camphor contains some water and volatile oil, but is not as impure as Chinese camphor. To convert it into compressed camphor it is placed in a still, and a moderate heat applied. The condenser is a large chamber, having projections so arranged as to lengthen the course of the vaporized camphor. In the first partition the product is mostly in the pulverulent form; in the last it crystallizes in beautiful snow-flake-like crystals. It yet contains water and volatile oil, on account of which the ordinary refined camphor is preferable for medical purposes. The crystalline powder is then placed in iron moulds which are moistened with water to prevent the camphor from adhering, and by hydraulic pressure pressed into rectangular blocks of various weights. The iron rust of the moulds somewhat colours the exterior of this camphor, which is used to prevent the ravages of moths, and the object of this form is to prevent too rapid evaporation. It was stated that very handsome refined camphor is now produced in Philadelphia, and also in New York. Refined camphor was formerly imported from Europe, where it is sublimed in glass spheres, which are broken to obtain the camphor. In the United States the subliming vessels are of a form that will allow of their being taken apart. The volatile oil contained in the crude camphor is also collected. The changes in this industry have been owing to the tariff.

Professor Remington remarked that the sublimed camphor, if free from moisture and volatile oil, might be used as powdered camphor, it being essentially the product recommended by Mr. John C. Lowd, in the Proceedings of the American Pharmaceutical Association, 1871.

Dr. A. W. Miller presented some Feé-jee nux vomica, so-called, and desired some information in regard to it.

Professor Maisch stated they were the seeds of *Strychnos potatorum.*

Dr. Miller also showed oil of sassafras containing 14 per cent. of resin, which is left upon evaporation, and was probably added as oleo-resin.

Professor Maisch exhibited American asbestos in its natural state as found in the United States, also the same purified, both being in very long fibres. The purifying process, which is patented, is based upon the use of acid, and afterwards forcing steam through the fibres, which are thus cleaned and preserved unbroken. It is intended to be used for filters, and fire-proof articles of small size.

Professor Remington had seen it applied in the manufacture of a small spirit stove. This stove heats quickly, and is convenient for travellers.

Mr. R. V. Mattison said it was used for making fire-proof paper by a company in Philadelphia, but as yet this paper was not in the market.

Professor Remington exhibited and described a percolator stand, made by Mr. D. Benjamin, Camden, N. J. It is not patented, and the inventor offers it as an effort to assist the apothecary who desires to prepare his own galenical preparations. It is difficult to explain the many advantages of this stand, but practical use in the laboratory will show its conveniences. It will hold any size of percolator from half a pint to sixteen gallons with perfect ease and firmness, by means of the adjustable clamps at the top. Several percolators and funnels can be used on it at the same time by means of the moveable folding shelves. There are two of these, which may be elevated or depressed, and held in perfect safety, and each has three folding parts; they can be adjusted to the height of any counter or stove, for holding condensers, receivers, funnels, and dishes. It is constructed of wood, occupies but little space either when in use or not, is neat, ornamental, and affords great protection to the apparatus in use; is not liable to wear or get out of order. In ordinary percolations or filtrations it covers the various sized instruments, excluding dust, and preventing evaporation, and is especially convenient for self-feeding percolators. It is a very good press for small operations, the mass being enclosed in a bag, then screwed up in the clamps and allowed to drain.

CHEMICAL SOCIETY.

Thursday, 17th December, 1874. Professor Gladstone, F.R.S., Vice-President, in the chair. After the usual business of the Society, a paper "On Groves' Method of Preparing Chlorides," by Dr. Schorlemmer, F.R.S., was read. He finds that the process does not answer well for the higher primary alcohols, although secondary chlorides can readily be prepared by it. The other papers were

"On the Precipitation of Metals by Zinc," by Mr. J. L. Davies; "Researches on the Paraffins Existing in Pennsylvanian Petroleum," by Mr. T. M. Morgan; Some remarks on the preceding paper, by Dr. Schorlemmer; and "A Note on Aricine," by Mr. D. Howard, who finds that this is really a distinct alkaloid existing in certain kinds of reputed cinchona barks.

The Chairman announced that Professor C. Maxwell had promised to give a lecture on the 18th February, "On the Dynamical Evidence of the Molecular Constitution of Bodies." The meeting was then adjourned until Thursday, 17th January next.

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act.

Adulteration of Pickles.

On Wednesday, December 16, Mr. Christopher Blade, chemist and druggist, was summoned before the magistrates sitting at Leek, Staffordshire, for selling as unadulterated a bottle of pickles, which, upon analysis by Mr. Scott, of Wolverhampton, was declared to contain a quantity of copper and a small amount of sulphuric acid, which he further declared to be injurious to health. An assistant to the inspector, said that on the 30th October, he went to defendant's shop and asked for a bottle of pickles. He was supplied with one, for which he paid 1*s*. At the time, he mentioned the purpose for which the bottle of pickles was required, and also informed the defendant when they would be forwarded to the county analyst at Wolverhampton. In cross-examination, the witness said that to the best of his knowledge he did not choose the bottle analysed; he did not remember seeing two bottles on the counter. The inspector spoke to receiving the goods, and forwarding them to Mr. Scott on the 3rd of November. The bottle was marked 8,428. Mr. Silvester addressed the Bench at considerable length on behalf of the defendant. He said it was a case of great importance to the manufacturers of the pickles, Messrs. Lazenby, of London. He also said it was well known that vinegar made entirely of malt would not keep, consequently there was no vinegar made which did not contain sulphuric acid, and he read an extract from an Excise Act, 38 Geo. 3, cap. 65, wherein sulphuric acid was permitted in small quantities. He asked the Bench to allow the remaining portion of the pickles to be analysed by some other analyst, and to adjourn the case until the answer came. After some conversation, the case was adjourned for a month, that the remaining sample might be analysed by Dr. Roscoe, Mr. Silvester reserving the right of asking for a special case.

Mr. Andrew Morton, grocer, was also charged with selling pickles as unadulterated, which were subsequently found to be adulterated with copper. The analyst declared the pickles to be distinctly injurious to health. The manufacturer of the pickles, Mr. Williams, of Manchester, was present, and said he was prepared to swear no copper could possibly get into the pickles in the process of manufacture. This case also was adjourned for a month.

Mr. Henry Bostock was also summoned for selling as unadulterated pickles which were found to contain poisonous matter. Mr. Johnson proved purchasing the pickles at defendant's shop on the 30th ult., and admitted that before the purchase was made the defendant said he would not warrant the pickles was pure. Under this circumstance, the magistrates considered the defendant had protected himself by declaring his unwillingness to guarantee the pickles, and therefore dismissed the case.

On the following day, at Tunstall, Mr. Boyce Adams, of Messrs. Adams and Lamb, grocers, Hanley and Tunstall, was charged with selling one bottle of adulterated pickles on the 23rd November. The certificate of analysis showed that the pickles contained a preparation of copper. Mr. Silvester, who appeared on behalf of Messrs. Lazenby and Son, manufacturers of the pickles, contended that the offence had not been proved, and that there had been no express representation that they were unadulterated. He also pointed out that the pickles had passed through several hands, and that the certificate was very vague and not reliable. He therefore asked for the other half of the bottle of pickles to be given up to an independent analyst to decide whether they were really adulterated. The case was adjourned for a month for an independent analysis to be made.—*Staffordshire Daily Sentinel.*

Adulteration of Pepper.

At Leek, on Wednesday, December 16, Benjamin Price, shopkeeper, was charged with selling one oz. of adulterated black pepper. Mr. Scott had analysed the pepper, and declared it to contain husks, starches, and micaceous and ferruginous sand, to an extent injurious to health. The assistant who proved the case, said that after the purchase had been made, and defendant had been told for what purpose it was wanted, he said he would not warrant it. Defendant was fined 5*s*. and costs.

Edward Walker, for selling 1 oz. of adulterated black pepper, on the same date, was fined 5*s*. and costs.—*Staffordshire Daily Sentinel.*

Conviction of Chemists and Druggists for selling Adulterated Precipitated Sulphur.

On Thursday, December 17, Mr. John Dixon, chemist and druggist, Tunstall, was charged before the magistrates at Tunstall with selling a certain drug—viz., "precipitated sulphur," on the 23rd November, which the analyst's certificate stated was adulterated with gypsum to the extent of 62 per cent., and injurious to invalids and children.

Defendant said had he sold the drug as "milk of sulphur," and not as "precipitated sulphur," he would not have been amenable to the law.

The magistrates said they had no alternative but to inflict a fine of 10*s*.

Mr. Joseph Keightley, chemist and druggist, Tunstall, was also charged with selling precipitated sulphur, which the analyst's certificate showed, contained 42 per cent. of gypsum. Defendant, who had nothing to say, was fined 10*s*.—*Staffordshire Daily Sentinel.*

Lead in Lemonade.

On Thursday, December 17, Andrew Stout, lemonade dealer, was charged at the Glasgow Central Police Court, before Baillie Young, under the Adulteration of Food, Drink, and Drugs Act, with having, on the 8th December, either by himself or his servant, sold two bottles of lemonade adulterated with lead, and thereby rendered himself liable to a penalty not exceeding £20.

Defendant pleaded that he had put no lead into the lemonade, but he had just put in a new receiver, and had some of the pipes lined with block tin.

Sanitary Inspector Walker said that he had purchased the two bottles of lemonade labelled, and paid fivepence for them. He said to the seller that he would take them to the city analyst, and invited him to go with him, but the accused declined. The inspector had previously called at Stout's place and informed his wife that lead had been found in soda water sold in the city, and that her husband should take care not to use lead pipes in the manufacture of his liquors.

The accused here said that he did not dispute the analysis, and that after he had been warned, he had as already stated put in a new receiver, and lined all the pipes with block tin.

Dr. Tatlock, city analyst, deponed that the lemonade in question was contaminated with lead to the extent of one-sixth of a grain per gallon—a proportion which clearly showed that lead had been employed in the construction of the apparatus with which this lemonade had been manufactured. In answer to a question he said that no lead should be employed in those parts of the apparatus with which the liquid came into contact. He always understood that lead was a mineral poison. He also understood that a very much smaller quantity was very dangerous.

Dr. Russell, medical officer of health for the City, said that his attention had been frequently directed lately to the fact that lead to a dangerous extent was held in solution in some descriptions of lemonade or soda water. This had become a matter of notoriety. Steps had therefore been taken by the inspector of nuisances. There were authentic cases on record where one-hundredth part of a grain of lead per gallon had produced symptoms of poisoning, and one seventy-fifth part of a grain in other cases. One-sixth of a grain was a very serious proportion. No person could partake of such an adulterated liquid without incurring very much risk. By the magistrate—Do you think that to a person drinking a bottle of such lemonade it is dangerous? Dr. Russell—Yes. By the procurator-fiscal—Is lemonade very often used in hospitals? Dr. Russell—It is used in all hospitals, and it is indispensable that it should be pure. I believe that the lead in this lemonade arises from the character of the apparatus. Those who make lemonade free from lead use a special apparatus.

The accused said that he had no witnesses, and that he did not know till now there was lead in his apparatus. He had made alterations to avoid this risk.

The Magistrate: You should consult Dr. Tatlock or some other analyst before you make alterations.

The Accused: Some of the manufacturers have put in block tin pipes, and have afterwards got an analysis made which showed that the liquid was pure.

The Fiscal: At Dumbarton there was a conviction for a somewhat similar offence. Such a penalty should be imposed here as would act as a check sufficient to prevent persons exposing the public to such dangers.

The Accused: It used to be all lead together. The receivers were all lead.

The Fiscal: You must not fill your pockets at the expense of the public health. I do not think you would willingly do it; but the public must be protected.

The magistrate said this was rather an aggravated case. The inspector had called and delivered previously a warning to the wife of the accused.

The Assessor: This is a far more dangerous adulteration than adulterated milk.

The Magistrate: The sentence of the Court is a fine of five guineas, and outlaid expenses 28*s.* 6*d.*

Adulteration of Milk.

At Greenwich Police-court, on Saturday last, Mr. Daniel Phillips, an extensive farmer and cowkeeper, of Lewisham, appeared to an adjourned summons at the instance of the Lewisham District Board of Works, charged with selling milk adulterated with water. Mr. Edwards, solicitor to the Board, attended to prosecute. Special interest was excited owing to the prosecution having three analysts in attendance to support the certificates made in this and other cases by Mr. Heisch, the district analyst, whose accuracy, or rather whose standard of milk-purity was questioned by Mr. Phillips, because in April last a friend of Mr. Phillips had drawn a sample of milk from a cow, and handed it to Mr. Heisch, who reported it as containing at least 12 per cent. of water, whereas, according to Mr. Phillips and his friend, it contained none.

On the evening of the 19th November, between six and seven o'clock, a girl was sent to the farmyard of the defendant by the inspector appointed under the Adulteration of Food Act, and obtained two pennyworth of milk from a servant to the defendant in a jug given to her by the inspector, who was in waiting, and who took the jug and milk from her to the wife and daughter of the defendant, telling them it had been bought for the purpose of analysis. The milk so bought was then placed in a bottle, which was corked and sealed, and was forwarded to Mr. Heisch, whose analysis showed an adulteration of 10 or 11 per cent. of water, and the present proceedings were instituted. The defendant had been twice previously summoned and fined on similar complaints. The correctness of the analysis being disputed, the case was adjourned. In support of Mr. Heisch's analysis Dr. Dupré, Lecturer on Chemistry at Westminster Hospital; Dr. John Attfield, Professor of Practical Chemistry of the Pharmaceutical Society of Great Britain; and Mr. Wigner, Public Analyst for Greenwich and Plumstead districts, were called. Dr. Dupré and Mr. Wigner stated that portions of the same milk analysed by them after the dispute arose (one analysis only taking place the previous day, the milk then being just a month drawn) contained as much as 12 per cent. of water. This was after making proper allowance for decomposition. The defendant produced two analytical certificates of milk drawn from the same cows, one, signed by W. Baxter, stating that the amount of solids, not fat, was 8·33 per cent., which on a standard of 9·3 per cent. of solids, as shown by the three analysts, was equivalent to 10 per cent. of water in the milk, or on a standard of 9 per cent. solids to milk containing rather less than 10 per cent. of added water. Respecting the April milk from the person since stated to be Mr. Phillips's friend, Mr. Heisch said he found it to contain at least 12 or 15 per cent. of added water and to be otherwise so abnormal that he placed samples of it in the hands of the three analysts for their opinion. The analyses all agreed and quite confirmed his own. Professor Attfield said he had analysed the April milk and found at least 12 per cent. of added water in it and three times as much common salt or chlorides as ought to have been present. A fair percentage of non-fatty solids in pure milk was 9·3, especially in the case of large dairies or herds of cows, but in order to give the milk-seller the benefit of any doubt, analysts assumed that milk placed in their hands for analysis had been yielded by the poorest cows, the minimum of whose non-fatty milk solids was 9 per cent. In reporting on the April milk he had taken 9 per cent. of non-fatty solids as a standard, a lower percentage than he had ever known to be contained in genuine milk from a herd of cows. Dr. Dupré said in answer to Mr. Balguy that it was admitted that there was so much difference of opinion among professional men that a meeting had been held, at which to fix the standard for analytical purposes, and although that standard had not been publicly mentioned hitherto it was said that some analysts have adopted 9·0 and others 9·3 per cent. He himself was in favour of 9·3, because if they adopted 9, which was the extremely exceptional minimum for the very poorest milk, milk-dealers would dilute all ordinary milk of fair average quality down to the quality of the poorest possible. But even taking the lower standard, these two milks in question contained 10 or 12 per cent of water. Mr. Balguy, in giving his decision, said the case was not only of public importance, but it was most important to the defendant himself, who, as the supplier of milk which was largely retailed through a wide district, ought to be above all suspicion. In the first place he had to remark that the evidence given for the prosecution was not to his mind of a satisfactory character, and that the sending of a girl by a public officer with a jug for the milk in the dark of the evening, when it could not be seen whether the jug contained any small portion of water, was a course of proceeding he should advise not to be again adopted in cases which were intended to be prosecuted. In these cases a man's character was at stake, and the charge ought, in common parlance, "to be proved up to the hilt." Neither the inspector nor the girl had turned the jug upside down to show that there was no water in it. He gave the analysts every credit for the accuracy of these analyses generally, but he was of opinion that there was evidently still a difficulty in accurately determining the question of standard, especially in a case in which the adulteration was stated to be so near as ten per cent. to the standard adopted by the analysts themselves. Then the defendants' friend had, indeed, sworn that the April milk was not watered. These doubts he thought the defendant should have the benefit of, and the summons would be dismissed. The defendant applied for costs, which, however, were refused.

Death from Poisoning.

Mr. Payne, city coroner, held an inquiry on Friday, the 18th inst., at Bartholomew's Hospital, respecting the death of Agnes Sophia Gilfin, aged 23. From the evidence it appeared the deceased was in the habit of taking a medicine to promote digestion, and on the Wednesday morning previous the deceased being in bed when her mother came to her, she said she had used the last of her own medicine and asked her mother to get some of the same medicine (out of another room) belonging to her brother, who also used it. Deceased's mother returned from the kitchen with a bottle and deceased took a dose, believing it to be the medicine; but almost immediately became ill and vomited. A cab was got and she was taken to the hospital. On the way deceased said, "What can I have taken? It must have been some of our William's (brother) poisonous stuff he cleans the clocks with." On being admitted she was found to be in a state of collapse, breathing slowly and heavily, and very pallid. The pupils of the eyes were much dilated. She had all the symptoms of poisoning. A stomach pump was applied, but to no purpose; she died in about fifteen minutes. An open verdict was returned.—*Times*.

Suicide by Chloroform.

At Selley Oak, Worcestershire, on the 16th inst., Mr. Docker held an inquest on the body of Deborah Frobisher, the wife of a chemist and druggist. It appeared that the deceased, after having sprinkled the bedclothes with chloroform, covered herself up, and died in a few minutes. A verdict of suicide while in a state of insanity was returned.

Reviews.

A Practical Handbook of Dyeing and Calico Printing. By William Crookes, F.R.S. London, Longmans, 1874.

We always receive technical handbooks of this kind with some degree of doubt. There is no question whatever about the value which a really complete and trustworthy book would possess, but the difficulties which beset the path of the author are so great as to render the task well-nigh impossible, even to a man of the highest attainments.

In the first place, technical methods are very commonly of a purely empirical nature, and often even the inventor himself knows but little of the *rationale* of his process; he cannot say why he used such-and such proportions of ingredients, or why a certain temperature will succeed and one a little above or below will fail. An equally great, or perhaps even greater difficulty, is the almost universal practice of secrecy. Whether wisely or unwisely, the majority of the processes in use are kept carefully concealed, either as a whole or, if this be impracticable, in part, some constituent or step in the process which is considered essential being kept secret. Even when a discovery is patented, it is doubtful if all the details, apparently insignificant, but yet really necessary to complete commercial success, are published. One result of this practice of secrecy, very important for our present purpose, is that a great proportion of the published processes are those which are thought to be of little value, in short *failures*, or untried and not very promising schemes which are freely made known, while the proved and successful methods are jealously reserved for exclusive use.

Mr. Crookes proposed to himself no light task in compiling a standard work on dyeing, calico printing, and their auxiliary arts which should "cover the whole of the subject" in 730 pages. His plan is of no less extent, for he objects in his preface to some other works, because "none of them can be said to cover the whole of the subject." We will now mention some of the subjects included in his scheme.

After an interesting introduction, giving a sketch of the history of the art of dyeing, the impurities encountered in water are considered in relation to dyeing, and a brief account is given of the general nature of fibres. Then the constitution of cotton is described in some detail, followed by an account of the process of bleaching cotton. After this, the bleaching and dyeing of linen, the nature of hemp and jute, the methods of distinguishing the principal fibres, the various kinds of "thickenings" and their use, the treatment of wool and silk, and the nature of the principal chemicals used, are successively described. The second division is devoted to the general principles of the fixing of colouring matter upon fibrous textures and the classification of dye materials. In this we find chapters on mineral pigments; artificial organic colouring matter—chiefly, of course, aniline, naphthalin, and alizarin products; organic colouring matters, not artificially obtained, such as madder and red woods, cochineal, orchil, indigo, galls, etc.; mordants; printing; and lastly, the detection of various dyes on the fibres. After this, an appendix of some thirty pages contains a number of processes, tables, etc., put together with little or no classification.

Such an extensive list as this will sufficiently show the large area over which the author passes, and will give an idea of the amount of condensation necessary to keep the book within such narrow limits as to size. The actual amount of matter included is perfectly bewildering, and we fear will somewhat detract from the value of the book. So many processes are given to attain the same end that one is often reminded of the old-fashioned cookery books with their incessant "another way." In consequence of this, we fear it will be of but little service to the inexperienced, for it is rarely stated that one process is better than another, and therefore the tyro would have to try several, and this under some considerable difficulties. For amid this wealth of recipes we find that a great many, if not the majority, are rather *outlines*, some important details being omitted. For example, the quantity of water to be used in a dye beck is very commonly omitted, and thus we are left in the dark as to the strength of the dye solution, a point which must often be of great importance. Many processes too, have the appearance of laboratory experiments which have never been tried commercially, or the results compared with products of established reputation obtained by other methods. Many old friends we meet with of this kind who we had hoped were dead ere this of mere inanition.

Faults of compilation and style are not few. We cannot look with any complacency on such words as "incrustating," "fixation," and "oxidisation," and we can only attribute to careless correction of proofs the repeated occurrence of the name "Cavento*n*" instead of "Cavento*u*." The indiscriminate use of old and new formulæ also gives great annoyance, and may lead to mistakes; carbonate of soda is sometimes NaO, CO_2, and sometimes Na_2CO_3; aniline is sometimes $C_{12}H_7N$, and sometimes C_6H_7N. Another fault of the same kind is the frequent mixture of systems of weight and measurement. We are told to boil 200 *kilos.* of dye wood in 80 *gallons* of water; and, what is of still greater importance, there is commonly nothing to tell us whether the temperature is given according to the Fahrenheit or Centigrade scale. It would not have greatly increased the labour of preparing the book if the numerical details had been reduced to some uniform system, and the solidity and usefulness of the work would have been largely increased. We cannot see the utility of the long account of the soda manufacture, occupying more than four pages, for no dyer or calico printer would ever make his own soda; and if he did, this account would be of no practical use to him, and the space would have been better bestowed on other matters. Even the more novel Weldon's chlorine process, valuable as it is, seems to us somewhat out of place here.

While we cannot think that this work covers the whole of its subject, since, apart from the difficulties attending the acquisition of information which we mentioned at the outset, it would be, in our opinion, impossible to squeeze the necessary matter into so small a space; yet we quite agree with the author "that it may still point out remunerative fields of research to the student," and probably its usefulness will lie chiefly in the way of suggestions to the initiated, while comparatively barren in the hands of the tyro. We can faithfully commend it as a storehouse, closely packed with matter, a careful examination of which could scarcely fail to be repaid by some valuable ideas and suggestions.

Searches for Summer: showing the Anti-Winter Tactics of an Invalid. By C. Home Douglas. William Blackwood and Sons, Edinburgh and London, 1874.

Mr. Home Douglas writes chiefly for those invalids, whether English or American, whose ailment is functional merely, and who, if transported to milder and more equably tempered latitudes, have a fair chance of recovery. For the organically or hopelessly diseased he would be very chary of prescribing estrangement from home, with its comfort and companionship. In this we believe him to be right; while in cases of the first-mentioned class he shows equal judgment in drawing the line between what climate can and what it cannot do.

To imagine, with many patients, that change of scene or sojourn in a climate milder or more bracing than the one they have left, absolves from strict attention to the regimen appropriate to the case is sheer nonsense; and climate as a therapeutic agent has often to bear the blame of failing to effect what should never have been expected from it. Efficacious, however, it cannot fail to be—if selected in accordance with the nature of the malady—its influence is reinforced by judicious management in the details of food, clothing, and exercise, whether of mind or body.

Mr. Home Douglas took his wife, who had for some time been suffering from spasmodic irritation of the respiratory organs, first to Gibraltar, then to Malaga, Cordova, and Seville, and finally through Madrid to Biarritz and Pau. Of all these places of invalid resort he gives minute estimates based on meteorological observations regularly made. Malaga, as a winter climate, he pronounces to be as nearly perfect as any in the world; though the patient must remember that not even there is the weather always fine, and that it will sometimes be his duty to keep the house for days. Mr. Home Douglas is a keen observer, with an appreciative eye for local humours and a graphic pen for their pourtrayal; and his descriptions of places, incidental though they are to his exposition, are very entertaining. Biarritz, that deserted haunt of the late emperor and his myrmidons, retains its climatic and scenic, while shorn of its social attractions, and the contrast between its past and its present aspect forms a very animated bit of writing in Mr. Home Douglas's book.

The remaining sections treat of Algiers and the Riviera; and both receive at Mr. Home Douglas's hands a more discriminating examination than has yet been vouchsafed them. The description of Algiers is particularly good—its meteorological virtues being analysed with the precision of a man of science, and its natural features reproduced with the vividness of a poet. In spite of its liability to sudden change of temperature, nay, even to tempestuous visitations, it might attract far more invalids than it does did it not share the chronic and deep-seated *malaise* of all French colonies. Compared with Malaga—the comparison is pursued with minute detail by Mr. Home Douglas—its climate is warmer in winter, though infinitely less steady; though usually fine, it is as fickle as that of Edinburgh in summer:—

"You are sitting out on your balcony at ten at night, in a flood of moonshine, the dark cypress trees seeming to whisper round you of everlasting peace. Imagination can hardly picture a calmer or more holy scene. But if fair as fairy land, it would hardly seem to be more substantial, for when you awake in the morning, behold! it has vanished! No mountains with dreamlike shades are there; in place of them a pale and sombre mist. And can that dull, barren, dimly visible plain be the same sea which you saw last night, dimpled with pools of silver moonshine, and breaking in diamond showers upon the shore? The beauty of the garden, too, is all gone. True, roses and lilies are still there, but soiled and bespattered as they are, they look like the belles of a ball-room who have fallen in the mud, or, if you choose, like gentle sprites who have become the prey of an evil genius now triumphant in the form of an Atlantic gale. For hours it will rage with the fury of a conquering demon, driving one tornado in fast succession after another over the livid landscape. There is no need to despair, however, as it is more than likely that before sunset it will have spent its fury, and that the morning will be ushered in with a north-east wind and a sky again serene" (p. 97).

Algiers, if less steady than Malaga, "has the pull" in its exemption from foul odours, for which, not only in their variety but in their intensity, Malaga bears the palm.

Habent sua fata Baiae: dogs and health-resorts have their day. Mr. Home Douglas's description of the Riviera points this moral, particularly in the case of poor Hyères, which figures so prominently in the domestic memoirs of twenty or thirty years ago. His account of Nice may be read with profit, certainly with pleasure, after Dr. Henry Bennet's elaborate treatise on the Riviera—indeed, the layman has the advantage of the physician in nearly every respect but a show of professional language. Mr. Home Douglas's programme for the invalid is so attractive; his climatic *menu* so "fetching" that invalids, real or supposed, will soon be "flying, flying south," like so many swallows or Scotchmen. In respect of literature alone his "Searches for Summer" has merits which are rare even in works of purely æsthetic or descriptive pretension.

A Year's Botany: adapted to Home and School Use. By Frances Anna Kitchener. Rivingtons. 1874.

We have seldom met with a book better adapted for interesting young people in the study of this science. Instead of frightening the student by presenting him with an interminable list of formidable technical terms, it leads him on step by step in an examination of flowers for himself, introducing the technical expressions only as they are actually wanted. At the commencement of each lesson a list of flowers is given with which the learner is to provide himself; the conspicuous points of structure are first of all explained; and then, before the student is wearied with a number of details of external morphology, the simpler and more interesting physiological processes are described in a manner that cannot fail to arrest the attention. This is a great improvement on the old method, by which many were deterred at the outset from prosecuting the study, and from which the science has got the evil and altogether undeserved repute of being extremely dry. The book ought to have a large circulation, especially among those who have children whom they wish to interest in a subject with which every one who lives in the country ought to have some acquaintance.

BOOKS RECEIVED.

HISTORY OF THE CONFLICT BETWEEN RELIGION AND SCIENCE. By JOHN WILLIAM DRAPER, M.D., LL.D., etc. London: H. S. King and Co. 1875. From the Publishers.

Notes and Queries.

ADULTERATION OF SERPENTARIA.—In the *American Journal of Pharmacy* for November, Mr. P. L. Milleman states that he has met with an adulteration of Radix serpentariæ by a large admixture of the rhizomes of golden seal with the rootlets attached. Serpentaria is found in the United States market generally in a loose and unpressed condition, and the practice of allowing its long twisted and knotted rootlets to retain some adhering earth facilitates the perpetration of the fraud.

ARTIFICIAL AGEING OF OIL OF CLOVES.—M. Stanislas Martin notices (*L'Union Pharmaceutique*, xv., 346) the occurrence in commerce of two kinds of volatile oil of cloves: one, which is amber coloured, being sold at 40 francs the kilogram; the other, mahogany coloured, being sold at 45 francs. These, he states, are frequently the same oil, the darker having undergone a manipulation based upon the fact that oil of cloves is coloured by exposure to light, and that its flavour improves with age. In order to hasten this change, the oil is exposed in unstoppered bottles to sunlight or the gentle heat of a stove, until it has lost rather more than one-tenth of its weight, and its specific gravity has been increased from 1·055 to 1·060. The alteration in flavour M. Martin considers to be due to the presence in the new oil of an empyreumatic oil which is volatilized at a low temperature; whilst the colouration he attributes to the oxidation of caryophyll, a certain quantity of which he has found to disappear from oil of cloves submitted to the influence of time or a forced evaporation.

DEODORIZATION OF CARBON BISULPHIDE.—M. Yvon states (*Journ. Pharm. Chim.*, xx., 377) that carbon bisulphide may have its disagreeable odour removed, sufficiently to allow of its use as an anæsthetic, by digesting it with copper turnings. No stirring is necessary; the carbon bisulphide quickly becomes colourless and then possesses an ethereal odour which has nothing unpleasant in it.

GRANULATION OF CHLORATE OF POTASSIUM.—The danger attendant on the pulverization of chlorate of potassium, may be entirely avoided by pursuing the method recommended by Gawalovski. A hot, saturated solution of chlorate is prepared, and into this is dropped a plate of glass. When the glass is withdrawn it is soon covered by a layer of the granular salt, which is removed, and the operation repeated until a sufficient quantity is obtained.—*Canadian Pharmaceutical Journal.*

LIQUID GLUE.—A writer in the *Comptes Rendus* describes a method of making liquid glue which remains liquid in bulk, and is still very tenacious when dry. Reduced to English weight the proportions of the ingredients are about as follows:—Two and a quarter pounds of glue are dissolved in thirty-six fluid ounces of water, in a glazed vessel set in a water-bath. Seven ounces, by weight, of nitric acid, sp. gr. 1·32, are gradually added, stirring well after each addition. This produces effervescence, hyponitrous acid being evolved. When all the acid has been added, the operation is finished, and the product may be set aside to cool.—*Canadian Pharmaceutical Journal.*

PRESENCE OF PERCHLORIDE OF MERCURY IN SACCHARATED CALOMEL.—Dr. Polk (*Philad. Medical Times*) corroborates the statement of Vulpius, that "when calomel is mixed in powder with white sugar, or calcined magnesia, or bicarbonate of soda, corrosive sublimate is formed in twenty-four hours." Dr. Polk found the administration of ten grains of saccharated calomel, which had been prepared a month previous, was attended with poisonous effects. Examination revealed the fact that a considerable quantity of perchloride of mercury was contained in the remainder of the sample.—*Canadian Pharmaceutical Journal.*

LEGISLATION FOR PROMOTING EARLY CLOSING.

Sir,—Allow me to thank you for your article of the 19th inst. upon our annual report. At the same time permit me to correct the statement that the Early Closing Association evinces any "disposition to coquet with 'permissive legislation.'" This phase of coercion was merely mentioned in our manifesto as one of the forms which legislation might take without the expression of any opinion upon its merits. Indeed, the document quoted concludes thus:—"Although the Board of Management are prepared to consider any well-devised project for legislating on the subject of early closing, thus far they see no reason to depart from their reliance on that mode of operation which has achieved such valuable results in the past—a method which has conferred inestimable benefits on multitudes without giving anyone reason to complain of coercion or injury."

In conclusion, I beg to add that chemists' assistants have occupied the thoughts of the Society upon many occasions, and that the enclosed pamphlet was issued in 1857 to call public attention to their case.

It has, however, been generally found that what is wanted is a greater spirit of concord and agreement amongst the employers rather than any interference or pressure from without.

FRANCIS A. ALLEN, *Secretary.*

100, *Fleet Street, E.C.,*
December 21, 1874.

DISSATISFIED YOUNG MEN.

Sir,—On reading the letter of "Veritas" I must confess I was somewhat taken by surprise. It seemed to me to be the words of a man who had been in a trance the last twenty or thirty years, and being just awakened, was looking about him with astonishment at the somewhat altered state of affairs.

It is true that we who are young, "by being brought on the stage in these latter times" have partially escaped the evils of which he speaks. I say, partially, for they still exist, though, perhaps not to the extent they did at the period to which your correspondent refers. But he seems to forget that it is *now* necessary that we must spend the whole of our leisure time in study for some years, unless we are content to remain "asses of the Pharmaceutical Society," for life. If the apprentices of the "good old times" were "fond of reading" I should like to know how they would figure before our "Board of Examiners." Would the majority of them leave the dreaded room at Bloomsbury

Square with smiling faces or downcast eyes? Let "Veritas" answer.

As for the interests of employers—or masters if "Veritas" prefers the term—being injured by closing at a reasonable hour, I would recommend him to ask the drapers, grocers, ironmongers, etc., with whom he transacts business, whether their returns have decreased of late years, since the system of early closing has been so generally adopted, and communicate the result of his inquiries to the *Pharmaceutical Journal*, as it would no doubt be interesting—though, perhaps, not new—to most of its readers.

I will admit that the men who have newly-established businesses are frequently the "chief offenders, in keeping shops open late at night;" but it must be remembered that they form only a small proportion of the total number in business, and that most of them are men of little or no capital, who, if the hours of labour were moderate, and the salary equal to that obtainable by assistants in other trades, would remain assistants.

"Veritas" does not seem to be aware of the fact that in the greater number of pharmacies, especially where only one or two assistants are kept, there are at times half hours when "business being slack" and "stock well up" he must necessarily be either doing nothing, or making his work "spin out," so that a superficial observer would be led to think him an industrious man. I am informed that in the "good old times," when "Veritas" was an apprentice, the assistant's time was "filled up" by "killing quicksilver" for sheep ointment, etc., etc.; but it is now found that that work may be more economically performed by porters and machinery.

Lastly, as regards Sunday duty. I think it would be most unfair for the master to have the whole burden of it upon himself, and no assistant who expected to be in business on his own account would wish for such a thing, especially as the Sunday trade offers more interruption than it formerly did, owing chiefly to the fact that many medical men have given up the old custom of dispensing their own prescriptions since the modern pharmacist has become competent and conscientious enough to be trusted with that responsible duty. I, for one, would be sorry to deprive "A Dissatisfied Master," or anyone else, of the comfort to be derived from the ministry of Dr. M'Auslane or any other reverend gentleman.

AN EXAMINED ASSISTANT.

PRESERVATION OF INFUSIONS.

Sir,—In your last impression, Mr. Barrett disclaims having used carbolic acid for preserving infusions, although he admits having tried it as an experiment. He assumes that I implied that he was in the habit of using these for the patients, which I confess I did. One of my authorities for stating so had the opportunity of knowing at the time, but either he or I in the description given to me must have misunderstood the use Mr. Barrett made of the infusions so treated. As he is not so enthusiastic as Mr. Barrett or myself, he has forgotten the particulars of his statements to me, although they are so indelibly impressed on my memory that I remember he said that Mr. B. found carbolic acid would keep concentrated infusions if so little as one-fifth of a grain were contained in the ounce when diluted. Our "Mutual friend," whose honourable position, qualifications, and attainments, we both respect, certainly informed me *bonâ fide*, and as he has communicated privately with Mr. Barrett, Mr. B. will agree with me that however "good-natured" he may be, his word is "above suspicion."

WM. MARTINDALE.

10, *New Cavendish St., W., December* 23*rd*, 1874.

Sir,—The battle of the infusions fresh *versus* concentrated, had I believed been well fought out and long since settled in favour of the former; the only point not ceded by the latter being that of convenience.

Some recent suggestions which might possibly be useful on the score of economy in hospital, although not likely to obtain in private dispensing, have again brought the topic forward for discussion. The traveller offering concentrated infusions, on being informed by the pharmacist that he prepares them fresh, is ready with the rejoinder, But what do you do on an emergency? This is suggestive: emergencies do occur, and, although not very frequently, must be provided for; it is only on these occasions that the pharmacist is justified in using anything but a freshly prepared infusion, and even then is not justified in adding anything which is not ordered in the prescription.

In an early volume of the *Pharmaceutical Journal*, Mr. Alsop advocated the process of preservation of fresh infusions by filling bottles, heating to the boiling point, and hermetically sealing. From time to time Professor Redwood, in his lectures, has pointed to this process as the best known, and when a student at the Square, some fourteen years since, I remember him opening a bottle of infusion which had been so preserved for four years, it was quite good at that time.

In September, 1863, *Pharmaceutical Journal*, vol. v. 2nd series, I advocated its adoption for the preservation of lemon juice, using, however, a lower temperature for this (150°), and should not now make these remarks but that I find from his letter that Mr. Gudgen and probably many others still adhere to tying over with bladders. Now I believe that the bladder itself is occasionally the cause of spoiling, and in the article mentioned advise the use of corks—not filling too tightly, but cut off and sealed over with a little melted beeswax. After some thirteen years' experience of Mr. Alsop's method with this slight modification, I feel satisfied that infusions so preserved are the best substitutes on emergencies for those freshly prepared.

CHARLES SYMES.

Liverpool, December 19*th*, 1874.

We have also received a communication from *B. T. K.*, in which he expresses a preference for the plan of preserving infusions described by Mr. Gudgen, which *B. T. K.* finds also answers admirably for the preservation of mucilage. Further, he suggests whether the addition of chloroform to an infusion might not give some ingenious analyst an opportunity of certifying to an adulteration. We think enough has been said now and on previous occasions (see Mr. Allchin's paper in vol. i. of the present series), on this subject to evidence that there is no very great difficulty in preserving—at least without decomposition—properly prepared infusions during a considerable time, without the addition of any extraneous substance.

Amorphous Phosphorus.—We have received from Mr. Postans a letter in which he expresses the opinion that Mr. Greenish has failed to satisfy the reasonable demands for information he apparently possesses in respect to the discussion of this question from a scientific point of view. As personal considerations are introduced into this matter we must decline to afford any opportunity for dealing with it under that aspect, and therefore confine ourselves to stating the mere purport of Mr. Postans's letter.

R. G. Gould.—Blaine's 'Veterinary Art,' or Tuson's 'Veterinary Pharmacopœia, including the Outlines of Materia Medica and Therapeutics,' published by J. and A. Churchill, price 7*s.* 6*d.*

E. Lloyd.—You are recommended to address the question to the Editor of a medical journal.

G. F. G.—We are unable to answer your question, which is one that should be submitted to a solicitor, together with a statement of all the circumstances.

W. J. S.—Barber's 'Students' Pocket Companion to the British and London Pharmacopœias,' published by Philip and Son, 32, Fleet Street, E. C., price 5s.

R. B. Cotterill.—Tinct. Phosphori Ætherea. Sliced phosphorus ℈j, sulphuric ether ℥vi ʒij; macerate for a month in the dark, and decant. (Beasley.)

C. C. Thresh.—The woody fibre may have been introduced from the cask in which the chicory was packed, or it may have had its origin in the meditullium of the chicory itself; most probably the former. You appear to have overlooked our answer to your former question, which was to the effect that we had failed to identify the fungoid growth, and recommended you to send a specimen of it to the Editor of 'Grevillea.'

R. H. Cumine.—We are not acquainted with any published formula for Tincture of Guarana. See some appropriate remarks upon the subject in the concluding paragraph of Mr. Moore's paper on Fluid Extract of Guarana, before, p. 463.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. M. H. Stiles, Mr. A. W. Jones, Mr. Druce, Messrs. Evans, Lescher and Co.

NOTES ON MOROCCO DRUGS.

BY ARTHUR LEARED, M.D., F.R.C.P.,

Late Lecturer on Materia Medica Grosvenor Place School of Medicine,

AND E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

† Specimens of the drugs thus marked are in the museum of the Pharmaceutical Society.

‡ Specimens of the plants thus marked are in the herbarium of the Pharmaceutical Society,

§ The drugs thus marked were not recorded in the last paper.

The arrival of further specimens of drugs from Morocco has enabled us to identify with certainty several which, in a former paper,* were doubtfully named or not identified at all, owing to the fragmentary nature of the specimens then received. We are also able to add several drugs not before enumerated.

Leaves, Flowers, and Plants.

Aflau.—This is *Mentha Pulegium*, L., not a species of *Thymus*, as before stated.

†Artim.—This is *Retama Ræetam*, not Spanish Broom. At Tangier, the name "Artim" appears to be restricted to this species, but some dried flowers received from Mogador, under the same name, include also, *Genista candicans*, L.,‡ and *G. linifolia*, L.‡ "Artim," is probably, therefore, a generic name for several leguminous plants used as food for cattle.

The bitter roots are said to be used by the Arabs for internal pains, and the shoots macerated in water are applied to wounds. The shoots much resemble in appearance those of *Sarothamnus scoparius*, but are slenderer, more branched, and the branchlets are longer.

Azeer.—These leaves are those of *Rosmarinus officinalis*, L.

Effersue, *vide* Roots, art. Ipherscul.

†El Halhal.—This drug consists of two plants, *Lavandula stœchas*, L.,‡ and L. *dentata*, L. The first named occurs in by far the larger proportion, so that *L. dentata*, L., may be, perhaps, only an accidental admixture. The flowering specimens received under the same name are those of *L. stœchas* only.

§El Habeeka.—A single flowering specimen only received. It is *Parietaria officinalis, L.* Common Pellitory.

†Ghassoul.—The structure of the fruit which is mixed up with the stalks and leaves, is evidently that of some calycifloral plant, with a half-inferior ovary, nearly allied to the genus *Mesembryanthemum*, but we have not yet succeeded in identifying the species.

A specimen of a plant received under the very similar name "Ghussul," or "Tegaghust," is a species of *Silene*, but is evidently not the plant yielding ghassoul, for *Silene* has a superior ovary.

Flayu, *see* Timza.

§Grom-azdo.—These leaves resemble, in general character those of the *Cratægus oxyacanthus*, L., and probably belong to some species nearly allied to it. It is used by women after parturition.

†§Khobaizeh.—The whole herb is used. It is *Malva parviflora*, L., and is readily recognized by its wrinkled fruit. This name would, however, appear to include other species of the Malvaceæ, for a specimen consisting of flower and leaf received under the name of "Khobaizeh," belongs to *Lavatera hispida*, Desf. It is used as a demulcent in catarrh.

†M'roy, Maroui, or Marout.—These are several ways of spelling the Moorish name for *Marrubium vulgare*, L. The specimens examined all belong to the variety *β. lanatum*.†

Marout Zarbe.—The leaves are those of *Salvia triloba*, L., a plant with a woolly stem and leaves, which may perhaps owe its Moorish name to its similarity in this respect to *Marrubium vulgare.*

†Ruta.—This name probably includes two or more species of *Ruta*; a flowering specimen received under this name belonged to *Ruta Bracteosa*, D.C., while the drug consists of *R. angustifolia*, Pers.

†§Sabardo, or Asbardo.—The green stem. These curious cactus-like stems belong to a composite plant. *Kleinia pteroneura*, D. C., nearly allied to the common groundsel.

The stem is about the thickness of the fore-finger, leafless, except at the top, where there is a rosette of leaves, furrowed externally, and has a large discoid pith; the branches are nearly equal in size, quite erect, and parallel with the stem, and remind one of a candelabra with a number of candles in it.

It is used externally for "pains in the hands and feet," (rheumatism?).

†Sadear, or S'dia.—These words are different ways of spelling the Moorish name for *Teucrium polium*, L. A nearly allied species, *T. montanum*, L., was used in this country during the last century under the name of Poly-mountain, and appeared in the list of materia medica of the London Pharmacopœia as late as 1763.

‡§Shiba-el Agooz.—This name is applied to a species of Artemisia, *A. arborescens*.

†Taserkina.—These are the leaves of a variety of *Thymus vulgaris*, L., which has the leaves tapering more towards the base than in the common form.

Timza.—This is not *Mentha sylvestris*, L., but *Mentha rotundifolia*, L., which is distinguished from the former by its wrinkled, obtuse leaves. We have also received *M. rotundifolia* under the name of "Menta." A specimen without flowers, which closely resembles in appearance the common *M. viridis*, L., except that the leaves are stalked, is called "Flayu." The taste, also, is similar to that of *M. viridis*.

†Zater.—This is not a *Thymus*, but *Origanum compactum*, Bth.

Seeds.

†Sanous.—This seed is that of *Nigella sativa*, L. It is small, about one-eighth of an inch long, with projecting angles, quite black and reticulated. It is supposed by some to be the fitches mentioned by Isaiah.

Bark.

†‡§Edro or 'Dro.—This is the bark of the *Pistacia lentiscus*, L. It has been identified from a portion of the plant received from Morocco.

Roots.

†§Ablaluz.—This consists of the rootstock and tubercular roots of *Asphodelus ramosa*, Moench. The rootstock is about two inches long and three-quarters of an inch in diameter; of a pale brown colour, with numerous fleshy fusiform tubercular roots attached to it of about the thickness of the forefinger. The taste is insipid. The roots seem very tenacious of

* *Pharmaceutical Journal* [3], vol. iii., p. 621.

life, giving off shoots without being moistened, and in dry air.

§ADAD.—This is a large, somewhat cylindrical root, more than a foot long, and about two inches in diameter. It has a crown consisting of several stems, springing from the contracted upper portion of the root. The transverse section is white and starchy, but, nevertheless, is hard and tough, and shows about six ill-defined concentric rings, marked with horny looking radiating lines, which, under a lens, are seen to consist of vessels containing matter resembling caoutchouc. This caoutchouc has exuded from several parts of the root, where it was apparently injured in the fresh state. The smell and taste of the root are aromatic. The root is certainly not that of *D. mezereum*, L., as previously stated. A leaf received as that of Adad appears to belong to some species of thistle. Leo Africanus* says of Adad:—"The herbe thereof is bitter, and the root is so venemous that one drop of the water distilled thereout will kill a man within the space of an hower, which is commonly knowen even to the women of Africa." It is taken for debility and low spirits. Not yet identified.

†§ARK ABU.—This root occurs in pieces varying from one-third to half-inch in diameter, and several inches in length. It is dark brown externally, with numerous closely placed annular ridges and numerous small warts, and is sometimes branched in the upper part like dandelion root. The meditullium is large, white, and starchy, occupying about two-thirds of the diameter of the root. The cortical portion is white internally, and has a ring of resinous-looking rays next to the meditullium. The taste is insipid. It is used for "pains in the bones" (rheumatism?). Not yet identified.

†ARK SUS.—This consists entirely of the subterranean stem of a species of liquorice; the plant yielding it is probably *G. echinata*, L., judging from its bitterness and longitudinally cracked epidermis.

†BERESIMIS.—This root has a thick brown spongy cortical portion, and a white soft radiate meditullium. It tastes somewhat like turnip, but without any pungency. Not yet identified.

†§EMSLEH ANDER.—This is a tapering cylindrical root, varying in thickness from half to one inch, and from six to nine inches long, deeply furrowed, and of a dark brown colour externally. It is readily distinguished from other roots by its black, horny, cortical portion, which has a polished or waxy appearance when cut. The meditullium occupies three-quarters of the diameter, and is generally of a more or less dark grey colour, with sometimes a paler zone next to the bark. The taste is sweetish and slightly bitter. It is used for sore eyes, the root being ground very fine and passed under the eyelids. The leaves and stems attached to the root are evidently those of *Verbascum sinuatum*, L.

§IFERSCUL.—This drug is the root of *Cistus salvifolius*, L. It is a hard woody root of three-quarters to one inch or more in diameter, with a rather thick spongy cracked bark of a peculiar greenish or olive brown colour. The meditullium is of a dirty white colour, and is hard and woody. The plant appears to have grown in a reddish soil, as the surface of the root bark is of a reddish hue. A plant received under the somewhat similar name of *Effersue* is *Pteris aquilina*, L. The taste is earthy, gritty, and very slightly aromatic. It is taken for palpitation caused by sudden fright, etc.

†L'FUELY.—This root is not that of *Raphanus sativus*, L., that esculent being known in Morocco under the name of "Fijjil." The root of L'fuely is from half to one inch or more in diameter, rather smooth, and of a dull, dark red colour externally, and whitish and very fibrous internally. It appears to have been of a fleshy character when fresh, the cortical portion being very loosely attached to the meditullium. The taste is saltish. Not yet identified.

†ODEN EL HALOOF.—This consists of a short, prostrate rhizome, terminating in a hairy bud, and giving off below a tuft of straight, unbranched roots of a reddish brown colour, about the size of a crow-quill, and finely striated longitudinally. The odour resembles that of arnica, and the taste is aromatic and somewhat acrid. It is taken for strangury. Not yet identified.

†§TAFRIFA.—This root is of a dull brown colour, from half to one inch in diameter, with numerous transverse striæ and a few scattered warts. The meditullium is white, and the cortical portion thick, white, and spongy. The taste is saltish and pungent. It is supposed to strengthen the nerves, etc. The leaves and flowers received as those of Tafrifa belong to *Statice mucronata*, L.

†TASERKA.—This is a large somewhat woody root, 12 or 18 inches long, two inches or more in diameter at the top, and much branched and tapering to half an inch in the smaller branches. The cortical portion is brown, spongy, and rather thin in proportion, being on the average not more than a line in thickness. The meditullium is of a yellowish colour, with the concentric rings not visible, and in many of the pieces the medullary rays are of an ash grey colour (perhaps from imperfect drying), and thus gives a distinctly radiate appearance to the meditullium. The root is almost tasteless. Attached to the root are portions of leaves which appear to belong to some species of *Carlina* or *Carduus*. It is taken to mitigate thirst.

†TOWSERGENT.—This is the root of *Corrigiola telephiifolia*, Pour,‡ Nat. ord. Illecebraceæ. Specimens of the plant in flower, from Morocco, are in the herbarium of the Pharmaceutical Society. Externally the root is pale brown and twisted, rather knotty at the top, more or less fusiform, from a quarter to half an inch in diameter, and from two to four inches long. Its internal appearance is very characteristic. The transverse section is of a yellowish white colour, with 3-5 concentric rings, which have a horny and translucent appearance. The taste is acrid, causing a tingling sensation like that produced by Senega. Leo Africanus says concerning "Tauzarghente." "This root, growing in the westerne part of Africa upon the Ocean seashore, yeeldeth a fragrant and odoriferous smel, and the merchants of Mauritania carry the same into the land of Negros, where the people use it for a most excellent perfume, and yet they neither burne it nor put any fire at all thereto; for being kept only in an house, it yeeldeth a naturalle sent of itselfe. In Mauritania they sell a bunche of these rootes for halfe a ducate, which being carried to the land of Negros is sold again for eightie or one hundred ducates, and sometimes for more." The root we have received is not so powerfully odorous as represented by Leo Africanus; it has a very faint odour, like that of orris-root.

†WASKIZA.—This root occurs in slender pieces, of

---

* Translation by John Pory. London, 1600, page 357.

a pale brown colour externally, barely a quarter of an inch in diameter, and about three or four inches long. The root is sparingly branched. Internally it is pale, with a large and faintly radiate medi-tullium. The taste is earthy and slightly acrid. It is used as an emetic. The plant received as Waskiza is *Euphorbia terracina*, L.

Exudations.

†Alkeptum.—This resin occurs in small yellowish, rather dirty tears, in colour and taste resembling American frankincense. It is probably the product of some coniferous plants. Its Spanish name, "Gomma di Pinezia," gives probability to this suggestion, indicating as it does that it is derived from a species of fir. The resin is used in urinary complaints, accompanied by pains in the loins and deposits in the urine. It is administered mixed with bitters and honey. Not yet identified.

PREPARATION OF PURE CARBONATE OF SODA, AND PURE CARBONATE OF POTASH.*

BY J. LAWRENCE SMITH.

Pure Carbonate of Soda.—For many years all the carbonate of soda used by me in mineral analysis has been prepared in the following method, viz., by making oxalate of soda and then decomposing it by heat. It can be described in the shortest possible manner by giving the figures and method employed for obtaining a given result. The carbonate of soda commonly used has been the crystals of ordinary sal soda, washed with a little water to detach the adhering dust, or if one has pure soda at his command it can be used to advantage. The oxalic acid used is the ordinary oxalic acid of the shops once recrystallized, of which recrystallised acid I always have a supply of several pounds in my laboratory.

Sixty-three grammes of oxalic acid and 143 grammes of sal soda are dissolved by heat in 200 c.c. of distilled water. Filter the solutions, if necessary. To the solution of soda, when cold, add the solution of oxalic acid, just hot enough to keep from crystallizing; add it by degrees, stirring well; after the mixture is completed, it is expected that the solution will have an alkaline reaction, to keep any trace of soda in solution; the oxalate of soda will be precipitated in great part shortly after the operation is completed. Let stand for a short while to cool completely, decant the supernatant liquid, add a little distilled water, break up with a stirrer the lumps of crystals that may have formed, throw on a filter over a Bunsen aspirator, using a six-inch filter, wash with about a half litre of distilled water, and let dry. This may be placed aside in a glass bottle if not needed at once for forming carbonate of soda; the quantity of dry oxalate produced is 30 grammes. To convert into carbonate project the oxalate little by little into a platinum capsule over a good-sized Bunsen burner; after being strongly heated, the oxalate is decomposed into the carbonate, and, if heated high enough to be fused, will furnish about 23 grammes of fused carbonate of soda; fused or not, dissolve in water, filter, evaporate to dryness, dehydrate over a naked flame, and granulate it by stirring when hot.

Double or quadruple the quantities above given may be operated upon at once with similar results. The carbonate of soda thus made is perfectly free from chlorine, sulphuric acid, silica, or other impurity that will interfere with its use in analysis.

Pure Carbonate of Potash.—It may be wrong to use the word pure in connection with the preparation of this substance in the manner to be described, as it may contain at the end of the operation a trace of nitrate of potash. The starting point is pure nitre, which is a cheap potash salt, and can be readily purified by repeated crystallisation; the other is oxalic acid, the commercial acid recrystallized once or twice. 50 grammes of pure nitre and 100 grammes of oxalic acid are placed in a platinum capsule; to this is added a small quantity of water, and heated over a gas-burner; before the mixture is entirely dry, a second portion of water is added and the heat continued until the mass is brought to dryness, at which time nearly all the nitric acid of the nitre is expelled. The heat is now continued and the whole mass brought to redness, breaking up the lumps with an iron rod, when the oxalate of potash formed will be decomposed into the carbonate; the mass is treated with water, filtered, dried, and granulated over the flame; this furnishes about 31 grammes of carbonate of potash, which, as I have already said, may contain a little nitre, but this in no way interferes with the ordinary use of carbonate of potash in making fusions. For this purpose I commonly mix equal parts of carbonates of soda and potash at the time they are required for use.

*From the *American Chemist*.

MATICO.*

As to what plant is the "real original" Matico there seems some doubt. There are at least "two Richards in the field," and each has some claim to the title. According to Hartweg, whose remarks are quoted in a recent number of the *Pharmaceutical Journal*, "Matico is the vernacular name applied by the inhabitants of Quito to *Eupatorium glutinosum*, or the 'chessalonga' in the Quichua language. It forms a shrub three to five feet high, which is common in the higher parts of the Quitinian Andes, where its properties were discovered some years back by a soldier called Mateo, better known under his nickname Matico (little Matthew), who, being wounded in action, applied accidentally the leaves of some shrub to his wound, which had the immediate effect of stopping the bleeding. This shrub happened to be the Chessalonga, which has since been called, in honour of the discoverer' Matico. That it is the true Matico of the inhabitants of Quito and Riobamba I have not the slightest doubt; both the leaves and specimens have been gathered by myself, and upon comparing the latter with Kunth's description I found them to agree exactly with his *Eupatorium glutinosum*."

This origin of the name Matico, it may be remarked *par parenthèse*, reminds us of that of the genus Quassia, which commemorates a negro slave named Quassy, who first discovered its good qualities as a febrifuge, and employed its bark and wood as a secret remedy against the malignant endemic fevers which were so frequent in Surinam. He was at last induced to part with his secret for a considerable sum, by a Swede named Rolander, by whom, in 1756, the wood was first brought to Europe. This perpetuation of the name of the discoverer in association with the plant connected with him is common enough not only in scientific but in popular use; thus the "Tinker's weed" of North America (*Triosteum perfoliatum*) has reference to a Dr. Tinker, who was the first to employ it in medicine as an emetic; and Mr. Ransted, the introducer of the common yellow toad flax (*Linaria vulgaris*) to the United States, where it has become an agricultural pest, is commemorated in its popular name, "Ransted weed."

In spite of this identification of *Eupatorium glutinosum* as the original Matico, it is certain that the plant so called in commerce is in most cases not that species, but an *Artanthe* (*A. elongatum*), the *Piper angustifolium* of older writers. This was introduced to English medical practice by Dr. Jeffreys, of Liverpool, who published an account of it in the *Lancet* for 1839. It was recommended for use in cases of diarrhœa and cholera, but its real value is as a styptic, not from any astringent properties, but from its mechanical action, the structure of the leaf promoting the coagulation of the blood. It is chiefly imported from Peru, but specimens in the Exhibition of 1851 were from the province of Chiquas, in the eastern

* From the *Gardeners' Chronicle*.

extremity of Bolivia. Another species of *Artanthe* (*A. adunca*) is sometimes substituted for *A. elongata* in commerce. This was the case during the American war in 1863. According to Professor Bentley, however, "it may be at once distinguished from the official Matico by being in a less compressed state, by the upper surface of its leaves not being so tessellated or rough, and by the almost entire absence of pubescence on the under surface of the leaves." The true officinal Matico, as imported, "consists of the dry leaves, stalks, aad spikes (some unripe, others ripe), more or less compressed into a lump, which has a greenish colour. The leaves are from two to eight inches long, veined and tessellated on the upper surface, downy beneath, with an aromatic slightly astringent warm taste, and an agreeable, aromatic odour."

Another plant, which has also obtained the name of Matico, is *Waltheria glomerata*, the leaves of which are used as a vulnerary in the Panama region, where the shrub is known as Pado del Soldado, or Soldier's Tree; and a story similar to that given above is connected with it. Dr. Seemann says that "the same story, with more or less variation, is told of many other vulneraries of Spanish America." Martius was inclined to consider that the true Matico was furnished by a species of *Phlomis*, but that genus is only represented in America by *P. fruticosa*, which has been collected in Mexico, where it was probably an introduction.

THE BOTANIC GARDENS AT SAHARUNPORE, NEAR MEERUT.

An Indian medical correspondent of the *Medical Press and Circular*, writing from Meerut, thus describes a recent visit to the Botanic Gardens at Saharunpore, near that city.

"These gardens formerly belonged to a native prince, who, seventy years ago, started the place, now extending over 200 acres. The visitor familiar with Chiswick, Kew, and the Regent's Park, the Horticultural Gardens, the Crystal Palace grounds, and flower-shows generally, must make allowances for heat and climate; the chances are, Balaam fashion, he will return pleased, will bless instead of curse the place, which I found most enjoyable in the early morning, when the grass was wet with dew and the birds and insects singing and buzzing so merrily. Some of the flowers were still asleep—for instance, the twelve varieties of gorgeous, glorious passion-flowers; others, for instance, the great white mushroom-looking blossoms of the moon-flowers, which had an "up all night at a midwifery case" appearance, were jaded and worn; others, such as Ipomeas, the red, the white, the variegated convolvuluses never looked more lovely, especially the jalap, a gay dandy, who had entirely sunk all acquaintance with calomel and scammony. Of the twenty-seven varieties of roses, the King's Acre and the gloire de Dijon do the best; of the geraniums, the scarlet single and Tom Thumb are most hardy, but will only live five years, compared to twenty at home; likewise the fuchsia lives only ten instead of thirty years. From March to September the young tender plants are sent with the greatest benefit to the Hills, but, just as with men, the changes of climate do not universally benefit the old, indeed, may do harm. Dwelling too long on a congenial theme, although neither oaks, bays, or laurels are here, time and space will not permit even to enumerate the treasures of Saharunpore; so let us hurry on along the avenues, just glancing at acacias, cypresses, palms, yuccas, tamarinds, teak, chestnut, mahogany, india-rubber, the logwood for diarrhœa, croton for constipation, eucalyptulus globulus with camphor-smelling leaves—the antidote for malaria if it would only grow where required, so far a matter of impossibility that even the specimens here so carefully tended are but poor. One tree cuts like under-done beef—I forget the name and also the specimen in the spacious museum, there being no catalogue. Thousands of dried plants in paper, fossils of fish, flesh, fowl, and probably of medical practitioners, discovered in the Sewaliks; specimens of henbane, attees, kamala, curious fir-cones, shells found in kunkur, also rock crystal, green and blue malachite, asbestos, and that curious sandstone which bends and gives like india-rubber. But it was a sin to pore over old bones or stone when the sweetly-scented flowers of all colours were arrayed in review order, the smartest outside, awaiting inspection. Sir John Lubbock should have been here. The creepers are very grand. A water-lily-like, feathery jasmin, the *Valans Indica*, is curiously beautiful. There are forty acres of Rhæa running to waste until the great secret is discovered how to separate the glutinous matter. There are scented flowers, leaves, and shrubs, also vegetables, besides an experimental farm, worth visiting. The natives, wonderful herbalists, know a great deal more than we give them credit for on this as on other subjects, and on certain days they troop in to worship certain flowers—the *Jasminum mogrum*, a special favourite. The sacred monkeys, to kill which would be sacrilege, give constant trouble, grubbing up seeds, rooting up plants out of mischievous curiosity.

ZYMOTIC POISON.*

BY J. DOUGALL, M.D.

About 100,000 persons are poisoned to death annually in Great Britain, of which upwards of 4000 die in Glasgow. The number attacked, represented by these deaths, probably amounts to 10,000,000. This frightful mortality is not confined to our country, but prevails more or less from the same causes in every community in the world. This is no mere figure of speech in regard to the cause of death, nor simply an hypothesis as to the quantity of lives sacrificed. I mean what I say—these persons die by being poisoned, while the registrars' returns authenticate the number of victims. Doubtless, some of you will be startled at this statement, and will be already reflecting on what can be the nature and source of the potent agent that plays such terrible havoc with human life. Of course, you will say, it cannot be any even of the most active poisons we have in our laboratories—it cannot be such as prussic acid, or arsenic, or phosphorus, or any of the salts of mercury; neither can it be strychnia, atropia, aconitia, conia, or digitalin—that we know is ridiculously out of the question. What, then, can it be? Is it of vegetable, animal, or mineral origin? Is it solid, liquid, or gaseous? Does it taste sweet, sour, bitter, nauseous, salt, acrid, or is it tasteless? Does it smell pleasantly, or offensively, or is it odourless? Is it transparent or opaque, coloured or colourless, acid, alkaline, or neutral? Has it any known reactions with chemical reagents, or other distinctive propensities by which it can be known? Is it a simple, binary, ternary, or quaternary body? What is its name? Who was its discoverer? Has it no antidote? In short, has it been seen at all?

Such a sequence of ideas is likely to evolve in the minds of you whose daily avocation brings you in frequent contact with the pharmacopœial poisons, the toxicology of which you are supposed to know. But the substance to which I allude in no way resembles any of the toxic bodies in the materia medica, excepting that it is in the fullest sense of the term "a deadly poison," and yet it cannot be contained in stoppered bottles, weighed in grains, nor measured in minims. Moreover, it differs from all other poisons in this particular respect, that while their actions are confined to the person affected, its action renders the individual poisoned, poisonous. One may, without risk to life, attend assiduously upon, and sleep nightly in the same chamber with a patient suffering from a toxic dose of strychnia, opium, alcohol, etc., *qua* these bodies; but one who has not already been attacked by, and, of course survived the conflict with this virulent entity in all its phases, could not do so with impunity in the case of a person suffering from its effects. He or she might escape, but the peril incurred would be great, as the patient's blood

* A lecture delivered before the Glasgow Chemists and Druggists' Association.

undergoes a kind of destructive distillation, whereby it and the tissues are converted into poison, the body being often literally soaked and enveloped in an atmosphere of keen infection; saliva, urine, fæces, breath, sweat, and skin scurf, may all be saturated with it.

This baneful entity is known by the generic term zymotic poison, from the Greek word ζυμη, leaven, and a person under its influence is said to be in a state of zymosis or fermentation. It has received this name, because, when it infects the blood, certain phenomena are evoked, very analogous to those caused by the addition of yeast to a substance susceptible of fermentation. Supposing it possible to add to an aqueous solution of grape, or other fruit juice, or a mixture of honey and water, a single cell of the yeast plant *Torula cerevisiæ;* this speck of matter may be about the size of a human red blood corpuscle, that is about the 2500th of an inch in diameter, and, of course, only visible under the microscope. Supposing, further, the solution is kept at a temperature near 70° Fah. Then in a fews days, probably hours, from the single cell millions are generated, so as to render the liquid turbid, and form a scum at the top, and a sediment at the bottom. During this process the temperature of the fluid is sensibly higher than the surrounding medium, and carbonic anhydride is evolved in large quantity. Ultimately the escape of gas gradually ceases, and the saccharine solution is now found converted into a mixture of alcohol and water, incapable of further fermentation. Now, to illustrate the other side of the analogy, supposing I were to wet the point of a needle with the smallest possible portion of lymph from the body of a small-pox patient, and push it under the skin of a person unvaccinated, who had not suffered from small-pox, then, a thousand chances to one, in a few days, perhaps hours, the recipient of the lymph feels out of sorts—has headache, backache, nausea, vomiting, thirst, a high pulse, and hot skin. In about three days after the onset of these symptoms, a papular eruption appears on the body which soon forms vesicles or blebs. These may be few or many, separate or confluent, but the clear fluid with which they are tumid has the same specific infective nature as that with which the needle was wet, which has obviously caused them; that minute portion having now probably multiplied to an immeasurable extent. If the patient survive, he or she is now insusceptible of a second attack of these symptoms, which I need scarcely say are those of small-pox, and the lymph innoculated by the needle is zymotic poison.

These, you observe, are both cases of pure infection, and the analogy is about as perfect as possible, considering that in the one case we are dealing with what, in a sense, is dead matter, and in the other with a living organism. You observed: 1. The minute speck of yeast and of small-pox lymph, which evoked their respective phenomena. 2. The elevation of temperature in both cases—the fermenting liquid is abnormally warm, the small-pox patient highly fevered. 3. The enormous multiplication of the yeast and of the lymph. 4. The yeast frothing to the periphery or surface of the fluid, and the small-pox eruption forming, as it were, lymph bubbles on the skin. 5. Both are infectious—a portion of yeast from the alcoholic solution would cause fermentation, a portion of lymph from the innoculated patient would cause small-pox. 6. The alcohol will not again ferment, the patient will not again take variola. 7. The saccharine solution will ferment, as it were, spontaneously, because torula cells are constantly floating about and fall on its surface—so may a person, as it were, take small-pox spontaneously, by breathing air contaminated with that specific poison. These are also both cases of pure infection, though in neither is the infecting agent previously visible.

Now, I have chosen small-pox to compare with fermentation, simply because it is a typical species of the genus zymotica, the other chief members of which are scarlatina, measles, diphtheria, typhus and enteric fever, and cholera. These diseases are generically related, in respect that they are caused by a something which, entering the blood, reproduces itself enormously, rendering the secretions and excretions of the affected person poisonous if inhaled or swallowed by a healthy individual susceptible to their action. Also that they commonly only make one attack, and always cause a hot skin and high pulse. Their specific differences are so remarkable and distinct that, with few exceptions, physicians think each zymotic disease caused by a separate poison. For example, the doctor may be called to see a patient who sickened two days before, and finds him complaining of thirst and headache; he is fevered, prostrate, the eyes suffused, the tongue probably dry, furred, and studded with red points, the throat swollen and tender, and the skin covered with an exuberant efflorescence of bright scarlet dots, and he pronounces the case scarlatina. Or the patient may have swelling of the eyelids, with eyes red, watering, and intolerant of light, sneezing, dry cough, and hoarseness, with difficulty of breathing. On the fourth day of the fever the skin gets covered with small red dots, which coalesce into slightly raised crimson crescentic blotches, and the case is diagnosed as measles. Or the patient may have stiffness about the neck, slight diarrhœa, nausea, pain on swallowing, salivation, fetid breath, the back part of the throat covered with specks or patches, like damp, dirty, wash-leather—symptoms indicating diphtheria. Or the patient may have frequent chills, a soft pulse, dry brown tongue, constipated bowels, heavy, flushed, smoky countenance, stupor, prostration, wakefulness, delirium. About the seventh day of the fever the skin is covered with irregular spots of a dusky or mulberry hue, at first disappearing on pressure, slightly elevated, but soon becoming persistent—symptoms showing the case to be typhus fever. Or the patient may have pains in the limbs, great weakness, loose bowels, with very offensive stools, which may contain blood, glazed dry tongue, with ammoniacal breath, a pale languid face, with a hectic flush on each cheek, clear eyes with dilated pupils, and the mental faculties unaffected. About the eighth day a few elevated and isolated rose-coloured dots probably are found on the abdomen or chest, vanishing on pressure, appearing in successive crops, which last two or more days; and the doctor finds himself face to face with enteric fever. Or the patient, quite well a few hours before, may have severe diarrhœa, with evacuations like rice-water, cramps in the limbs, causing the muscles to be hard as wood, or contracted into knot-like masses; the circulation and respiration impeded; the nose, tongue, ears, breath, and extremities icy cold; the lips and general surface, blue or livid; the eyes sunk, the pupils contracted and fixed, the complexion muddy, and the features pinched; the whole body shrunk and intensely prostrate; perhaps death taking place before the doctor has time to prescribe for what is too obviously a case of Asiatic cholera. The differences in the symptoms of these diseases are held as sufficiently pronounced to justify medical practitioners, as already stated, in regarding them as specifically distinct. But, moreover, they have other characteristics which seem to prove this beyond a doubt. Supposing a person exposed to any of these distempers, and becoming infected, he would only suffer from the symptoms peculiar to the virus he had imbibed; if it were that of scarlatina, he would be affected with scarlatina only; and should he infect others, it would be with scarlatina and not small-pox, typhus, or cholera; and so with the others, each producing offspring identical in kind, though varying in degree, with the primary poison. Another strong proof of the specificity of the causes of zymotic diseases, is the fact already noticed, that one attack usually confers immunity from a subsequent attack of the particular disease with which the person is affected. Furthermore, an attack of one zymotic affection does not confer exemption from attacks by the other members of the group. Notwithstanding these strong and convincing proofs that zymotic diseases are the results of specific causes, some have endeavoured to show that there is one common cause to all, and that the variety in the disease depends upon the channel by which the noxious agent enters the body. If it come directly in contact with the blood, it is said to cause syphilis, dissecting wound fever, and other cognate diseases; if swallowed, enteric fever, and cholera; if breathed, scarlatina, measles, etc. These views are especially advocated in a pamphlet published three years ago on the correlation of zymotic diseases, by Mr. Wolff, of London; and although, judging from the present state of our knowledge, it is possible he may, to a certain extent, be correct, still a large balance of evidence points in the opposite direction. For example—small-pox matter only produces small-pox, by whatever channel it enters the body. I now come to consider the probable nature of zymotic poison. This question has engrossed the attention, and, I may say, baffled the skill of the most profound thinkers and patient workers in medical science. It has been fertile in endless and fruitless discussions; it has elicited untold, deeply interesting, but unprofitable memoirs; it is susceptible of the most ingenious, fascinating, but vain speculations; and has been the incentive to numberless of the most delicate, protracted, and even dangerous, but withal, valueless experiments. All the logic of the reasoner, all the results of the experimenter, anent the nature of zymotic poison, have hitherto practically ended in vague theories and conflicting hypotheses; such being the case, you will not of course expect a solution of the question from me, I can only promise to lay before you some of the more prominent points on which observers have dwelt, and some of the conclusions at which they seem to have arrived.

There are two leading theories extant of the nature, origin, and operation of zymotic contagia, viz., the germ theory, and the physical, or physico-chemical theory. Believers in the germ theory hold that zymotic diseases are caused by living vegetable organisms or ferments, or fungus spores, which, entering the body, reproduce themselves, and pass through various changes that evoke the characteristic phenomena pertaining to the special organism in the body, which may be a scarlet-fever germ, a small-pox germ, a cholera germ, etc., each disease having its special ferment or germ. This theory is founded on the analogy between zymotic disease and fermentation already noticed, and also putrefaction, because the blood and other fluids in the body of a zymotic patient seem undergoing a putrescent change. The germs theorists also affirm that putrefaction, in all its phases, is originated and maintained by germs, which, especially in densely populated places, are floating in myriads in the atmosphere, and only need a congenial soil, such as dead organic matter, or a weakly vital organism, in a condition favourable for their reception, to set them fructifying. Now, in order that you may fairly comprehend the theory, it is necessary to say something of putrefaction. If a portion of urine, blood serum, flesh-water, or other animal fluid be set aside for twenty-four hours, and then examined microscopically, it will be found swarming with organisms in active motion, called, generically, monads, bacteria, and vibriones. The first, from their being the smallest and simplest of all animalcules, measuring from 1-40,000th to the 1-100,000th of an inch; the second, from their rod-like shape, and the third from their vibratile movements. The fluid also soon gets slightly turbid, and distinctly fetid; its reaction is neutral or alkaline, but never acid. It continues thus about twelve months, when the organisms, turbidity and fetor, gradually disappear, and it now gives no response to the tests for albumen. These are the chief physical phenomena constituting putrefaction, and bearing on zymotic disease. But if a portion of any of these substances be put into two flasks and boiled a few minutes, and during ebullition the necks of the flasks stuffed with cotton-wool, and the steam allowed to issue through it a short time, and if the flasks be now set aside, their contents will be found months after, pure and unchanged. If the plug be now removed from one of the flasks, then in a few days its contents will begin to putrefy, while those of the other flask keep sweet and clear. Furthermore, if a portion of a putrescible fluid be boiled in a flask with the neck drawn out into a tube and bent downwards, and if the tube be heated so as to destroy any particles present in the air, which enters the flask as its contents cool, these will keep pure and fresh for an indefinite time; nay, here is such a flask (flask shewn) with flesh-water boiled in it ten months ago, and where the tube was not heated as the contents cooled, and yet these shew no signs of decay. Again, if the bent tube be broken so as to leave about an inch projecting from the neck of the flask, the result is the same as the withdrawal of the plug of cotton—in a short time the contents putrefy.

Now, these experiments show it is not the air which causes putrefaction, because the cotton-wool is pervious, and the bent tube open, neither can the cotton have any antiseptic action on the fluid, nor chemical effect on the air, because, as in the flask with the bent tube, it is dispensed with altogether, and yet the result is the same. The cause of putrefaction must therefore be something in, but distinct from, the atmosphere, and this something is obviously filtered by the wool from the air entering the flasks, while it cannot fall into the bent tube, as the orifice of the latter looks downwards, and, there being no currents in the flask, neither can it rise upwards in the tube.

Now, for no other reason that I know, than that monads, bacteria, and vibriones, are found in all putrefying fluids, the germs of these organisms are said by the germ theorists to be *the something* that is stopped by the cotton, and by the tube. M. Pasteur, a distinguished French micrologist, a brilliant experimenter, and chief of the germ theorists, has, it is said, even seen those germs in cotton-wool which had served as a filter in such experiments. Not only so, he has, by an ingenious process, actually managed to sow them in nitrogenous soil, and they gave rise to living organisms. Now, this looks very beautiful, but I am sceptical about it. Let it be admitted, however, that, *omne vivum ex vivo*, that no plant or animal, however minute, arises *de novo*, but springs from a pre-existing germ. What, then, must be the size of those germs which give rise to organisms of about 1-40,000th and less of an inch in diameter? A drop of a putrid solution, according to Ehrenberg, contains as many as there are human beings on the surface of the globe, viz., about 500,000,000. Why, if their germs bear the same proportion to their adults, as that which obtains between the germs of plants or animals familiar to us, and those when fully developed, the difference in some cases may amount to no more than tens of thousands, but in others it must be hundreds of millions. Compare, for example, an acorn with an oak; a turnip seed to the large succulent bulb it produces; the human germ measuring about the 250th part of an inch, to a man weighing sixteen stones, and it will be obvious that the germs of organisms in putrefying fluids, if such exist, are minute beyond comprehension, and that the highest powers of the microscope must ever be immeasurably inadequate to detect their presence. But it is by no means proved that all life comes from pre-existing life. The ingenious and apparently exhaustive experiments of Dr. C. Bastian, are to my mind as convincing as those of M. Pasteur, and these go to prove that many minute organisms arise *de novo*, or, in other words, that life may spring from that which has no life. Dr. Bastian, while admitting that urine, weak infusion of turnip and of hay, boiled in flasks with bent necks or with necks stuffed with cotton wool, may remain for an indefinite period without becoming turbid or undergoing any apparent change, has found that if the turnip solution be neutralized by ammonic carb. or liq. pot., or even if half a grain of new cheese be added to the infusion before it is boiled, the fluid soon gets turbid, owing to the appearance of multitudes of bacteria. In short, he has shown that in these experiments only certain weak nitrogenous fluids do not change, while solutions of a more complex nature produce living forms in abundance.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, JANUARY 2, 1875.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W.* *Envelopes indorsed "Pharm. Journ."*

1874.

Now that "the old year lies a-dying" we again take up the pen to record as best we may the pharmaceutical history of another year. To "gather up the fragments that nothing be lost," and arrange them as a consistent whole, is a task of no slight difficulty; but the interest and value of the result is in proportion to the completeness with which it is performed. Therefore, as we have the ambition to hope that these periodical reviews may prove acceptable to the pharmacist of the future as well as to his representative of to-day, we shall, notwithstanding the multiplicity of subjects, do the work as thoroughly as lies in our power.

The important modifications that have been introduced into the mode of conducting the Pharmaceutical Examinations this year have attracted, perhaps, a larger amount of attention from pharmacists than any other subject.

The Preliminary examination, to speak of that first, came to the front early in the year, in consequence of a Report from a Special Committee appointed by the Council to consider certain proposals from the Board of Examiners in reference to the Preliminary and Prize Examinations and the JACOB BELL Memorial Scholarships. This Report, whilst recognizing the valuable services rendered by the Local Secretaries in previously conducting those examinations gratuitously, and generally in their own houses, recommended that in future the examinations should be held in hired rooms in a limited number of towns, under the superintendence of persons, especially appointed by the Council, who should be called superintendents of examinations, and receive a fee for their services. These suggestions were adopted, and the wisdom of them will be obvious if it be remembered that this examination, like the Major and Minor, is no longer only a preliminary test of the examinee's fitness to enter a private Society, but is also the first step in testing his qualification to exercise a public privilege conferred, under certain conditions, by Act of Parliament. The time had passed, therefore, in which this examination could be looked upon as a *quasi* private affair, requiring or allowing of voluntary services. Sundry other regulations having the same tendency were also adopted in order to avoid any appearance or possibility of partiality or unfairness, and at its meeting in March the Council appointed Superintendents and Deputy-Superintendents for fifty-two centres of examination in England, and seven in Scotland. During the year 1251 persons presented themselves for the Preliminary examination, of whom 601 passed, or 48·04 per cent., contrasting rather unfavourably with 1873, when out of 1454 candidates 765, or 52·61 per cent., passed. At the October examination the amended regulation, requiring a thorough knowledge of the British and Metrical Systems of Weights and Measures, came into operation, and in January the Council decided that medical Latin should be discontinued in the Preliminary examination after the end of the year 1874. Notwithstanding these alterations and improvements there has been a manifest growth in opinion that this purely scholastic examination should not be conducted at all by the Society; and a motion made to that effect by Mr. ATKINS at the Annual Meeting failed not so much because it was opposed as because it was unexpected.

The approach of the time for enforcing the amended regulations for conducting the Minor and Major examinations, which were adopted by the Pharmaceutical Society and sanctioned by the Privy Council in 1873, was marked by what might almost be termed an examination panic. The number of persons seeking to pass the Minor examination increased at each successive meeting of the Board of Examiners until it culminated in June at 343. Of course, where the passing of the qualifying examination under the least stringent conditions was so manifestly the main object, the inevitable sequence was the appearance in the examination room of an unusually large proportion of imperfectly educated men. The result is obvious. Of 1064 Minor candidates, examined under the old regulations, only 352, or 33·08 per cent., passed, against 51·95 per cent. in 1873; and on the last occasion in London the percentage of successful candidates fell below 32 per cent. It is matter for regret that in some quarters the true significance of these figures has been misconstrued, and instead of adequately estimating the value of the services of the Board of Examiners to the cause of pharmacy, it has been implied that the painful duty of the Board ought to have been further complicated by a consideration of the possible effects the rejections might have upon the supply of assistants. It is yet too early to judge whether the more practical form which the Minor examination now takes will fulfil Dr. GREENHOW's prophecy in combatting the evils against which it is directed, or whether its failure will strengthen the hands of those who demand a compulsory curriculum.

The statistics of the Major examination are somewhat more satisfactory; for although the number of candidates has been somewhat smaller the proportion successful has been larger. The figures are—1873: of 83 examined, 54, or 65·06 per cent., passed;

1874: of 69 examined, 51, or 73·91 per cent., passed. We think it would not be too much to assume that the result of making the Minor examination a more searching test of a thorough pharmaceutical education will be manifested in a larger number of men seeking the then not so far removed Major qualification, and a larger proportion of them obtaining it.

It is satisfactory to know that the whole of the modifications in these examinations, conducted by the Pharmaceutical Society on behalf of the public, have the emphatic sanction of the Government visitors, Dr. GREENHOW and Dr. MACLAGAN; and it may be hoped that the words used in his last report by the former respecting previous alterations may be extended to those now on their trial—that "they have worked satisfactorily as regards the candidates themselves, and advantageously for the public service." With a view of securing as much uniformity as possible in the conduct of these examinations there has been an interchange of visits by deputations from the Boards in London and Edinburgh.

The only other alterations that need notice here relate to the prize examinations. The JACOB BELL Memorial Scholarships examination being now entirely a written one it has become possible to hold it at any of the examination centres concurrently with the July Preliminary examination; whilst in future the examination for the Pereira Medal and Prize of Books will be held in London and Edinburgh only.

This portion of our *résumé* would be incomplete without an allusion to the large amount of attention that has during the year been directed by public men towards examination as a means of testing education; and especially to speeches on this subject by the Bishop of Exeter and Professor Huxley.

Though somewhat in reversal of a natural order, the consideration of Pharmaceutical Education may well follow here. Concerning the success or failure of the important changes effected last year in the Society's School of Pharmacy it is yet premature to speak with certainty, the more so as the subject is now under the consideration of a Committee. So far, however, as may be gathered from the reports of the Professors, from an educational point of view they are working satisfactorily. Professor REDWOOD thinks the two five months' courses of lectures preferable to one of ten months, and Professor BENTLEY appears to give a general acquiescence to his views; whilst Professor ATTFIELD reports favourably of the laboratory, although he looks forward to the time when the School will revert to the ten months' courses of lectures.

An unusual amount of discussion respecting education has taken place during the year, especially in its aspect towards what is popularly termed cram; and it has been thought in some quarters there has been a disposition, in Mr. GILES's able address and on other occasions, to animadvert upon particular schools. It is only necessary to turn to the Council's report for the key to the position of the Council in respect to this subject, as given in the following definition, that "although it is one of the objects of the Society to promote pharmaceutical education, it is not its duty to defray the cost of educating young men coming into the trade." From this it may be gathered that the executive of the Society is inclined to welcome every effort to provide self-sustaining means of education; and as we have before said, "where a shadow of obloquy has fallen upon school or pupil it has been perceptible to the outside world only in proportion as the one has advertised its willingness to provide methodical assistance in baffling the examiners, or the other has sought out and adopted such methods." Nevertheless, the Council has always shown its readiness to go beyond this point, by contributing from the Society's funds towards the provision of educational facilities, and although Mr. SCHACHT's proposal in January to establish ten scholarships was not adopted mainly for financial reasons—a course which was ratified by the Annual Meeting—the Council recently voted fifty pounds to assist a provincial school at Manchester, which was thought to have made out a fair case. But one of the most remarkable features of this question is that the praiseworthy offers of the employers in different parts of the country to assist unexamined men to prepare for the examinations have met with such slight response as to put but few associations in a position to ask for grants in aid. This was recognized at the Annual Meeting by an unsparing critic of the Council, Mr. ATKINSON PICKERING, when he admitted that he now felt ashamed so small a portion of the funds had been applied for by the provincial members in aid of pharmaceutical education. There can be little doubt that Mr. SANDFORD spoke the feeling of the other members of the Council at its last meeting when he said he would like to have an opportunity of considering a score of other applications for £50 grants. Probably many of those who now neglect to make use of these facilities will live to realize the fate of those who fail to seize the forelock of Opportunity when it presents itself.

> "Rem tibi quam nosces aptam, dimittere noli;
> Fronte capillata, post est Occasio calva."

The value of apprenticeship as a practical means of education has been enforced; the object and necessity of a pharmaceutical education have been described by Professor MAISCH; and a valuable address on Study has been delivered by Dr. SYMES: these are but representatives of many other papers and addresses on the same subject. It will also be appropriate to notice here that the accomplished Yorkshire College of Science and the projected West of England College deserve the welcome of all who are interested in the teaching of science.

The year 1874 has been rendered notable in the history of the Benevolent Fund by some fundamental alterations in the rules and in the principles upon which the Fund had previously been administered. The probability which existed during a short time that in 1873 only one person would be elected as an annuitant upon the Fund, provoked a considerable amount of expostulation against the practice by which the total amount of annuities granted was limited to the interest received upon invested capital. This led to the appointment of a Special Committee to consider the subject, which presented a report in February. To this Committee Mr. Robbins, who had devoted much attention to the subject, submitted a proposition to increase the number of annuitants to twenty and rely upon a consequent increase in the annual subscriptions to make up the sum required. Although the Committee did not feel justified in recommending the Council to fetter the action of a succeeding Council, it was understood to concur in the spirit of Mr. Robbins's proposals. Upon its recommendation, therefore, and with a view to create a more general interest in the Fund, the Council decided to make an important alteration in the relation of the number of votes to subscriptions. Previously, each half-guinea subscribed had entitled the subscriber to one vote at each election of annuitants. Without altering the number of votes appertaining to Membership and Associateship respectively, the number of votes in return for subscriptions was doubled,—each half-guinea subscribed now entitling the subscriber to two votes,—whilst the power of giving a single vote was extended to every subscriber of five shillings. Although the subject of increasing the number of annuitants was tentatively mentioned in the Report of the Council presented at the Annual Meeting in May, it did not elicit much discussion, and what little was said was more conservative in its tone than might have been expected from the tenor of the numerous letters that had appeared in this Journal from time to time. Nevertheless, the new Council, at its first meeting, in June, resolved upon the motion of Mr. Bottle (the Vice-President), that four pensioners on the Benevolent Fund should be elected in the following October, bringing the number of annuitants up to seventeen, receiving £30 each. It is satisfactory to know that this policy has been endorsed by an increase in the year's receipts on behalf of the Fund of upwards of £150, whilst in no case has a subscriber of 10*s*. 6*d*. reduced his subscription to 5*s*., as had been feared. At the last meeting of the Council, amongst some other amendments in the regulations of the Fund, it was proposed to further reduce to 2*s*. 6*d*. the amount of subscription entitling to a vote. This proposition, however, was overruled, to the regret of the Secretary, who was hopeful of an extension of the area of subscribers by this method. We hope to be excused for remarking that in this, as in many other operations of the Society, the services of the Local Secretaries are indispensable; but some idea of how much remains yet to be done towards making the interest in this Fund coextensive with the bounds of British pharmacy is suggested by the fact that only about one half of the Society's Local Secretaries are themselves subscribers to the Benevolent Fund.

The question of Female Students has again cropped up in consequence of a request to the Council from Professor Attfield for permission to comply with some applications for admission to the Laboratory course. Mr. Hampson moved that the request be acceded to; but after discussion it was resolved that under the present arrangements the Council could not agree to the reception of female students in the Society's laboratory.

The Annual Meeting of the Pharmaceutical Society was, as usual, held in May. No particularly exciting topic was broached; but a general approval was expressed of the manner in which the affairs of the Society had been managed by the outgoing Council. The Benevolent Fund, the Proposed Scholarships, and the Preliminary Examination were the principal subjects discussed, with results that are mentioned under their respective heads.

As consequent upon the presence of many members of the Society in London to attend the Annual Meeting must be mentioned the Annual Dinner at the Crystal Palace and the Conversazione at South Kensington. Nor must the Chemists' Ball in January be forgotten.

We are glad to note that there has been a great improvement in the Evening Meetings of the Pharmaceutical Society since we had occasion to call attention to the subject last year. The present session especially, inaugurated by a most able address of Mr. Giles to the students, has been well supplied with papers, which have been followed by interesting and animated discussions. There is still, however, room for much improvement in respect to the attendance. The principal subjects brought forward have been—A Note on Iodide of Iron, by Mr. W. M. Holmes; Note on a Decomposed Lozenge, by Mr. T. Greenish; A Peculiar Camphor from China, by Mr. D. Hanbury; The Chemistry of Ngai Camphor, by Mr. S. Plowman; A Method of Storing and Dispensing Small Quantities of Hydrocyanic Acid, by Mr. F. B. Benger; Note on Chloro-Mercurate of Morphia, by Mr. W. Martindale; Tincture of Perchloride of Iron, by Dr. De Vrij; The Additions to the Pharmacopœia, by Mr. Charles Umney; The Nomenclature Proper to an International Pharmacopœia, by Mr. T. Greenish and Professor Attfield; The Pharmacy of Amorphous Phosphorus, by Mr. A. W. Postans; An Additional Test for Glycerine, by Prof. Godeffroy; The Preservative Effect of Chloroform upon Vegetable Infusions, etc., by Mr. J. B. Barnes; and The Preservation of the Liquid Extract of Liquorice Root, by Mr. C. Umney.

The Library has been enriched by the addition of about one hundred works, nearly half of which have been presented. These are in addition to the completed volumes of about forty periodicals which are purchased or presented. The average attendance of readers is hardly so high as might be expected in so valuable a library, being about 15 in the daytime, and about 6 in the evening. Last month, in compliance with the request of a petition presented to the Council by a number of the students, a Conversation Room was provided, which will be open to persons entitled to use the Library daily, except Saturday, from 5 till 10 p.m. The Library is consequently open now from 9 a.m. to 10 p.m.

Under the superintendence of the Museum Committee and the active care of the Curator, the Society's Museum at Bloomsbury Square has been rendered even more valuable as a means of study and reference than in previous years. During the last twelvemonths no less than one hundred and twenty specimens have been added to the General Collection, and one hundred and twelve to the Herbarium. The Collections of Brazilian, Chinese, Morocco, and Indian Drugs have been arranged, and many of the specimens previously unnamed have been identified. Last year we referred to a Catalogue that had been prepared and we expressed a hope that it would be printed. This Catalogue is now being enriched by historical and explanatory notes which will make it useful, for reference, both to students and business men. A portion is already in the printer's hands. All the Museum specimens are being numbered to correspond with numbers in the Catalogue. The Museum, like the Library, is now open during the evening.

The North British Branch of the Pharmaceutical Society appears to be making satisfactory progress; about eleven hundred attendances in the library, reading room, and museum during the year having been reported. In May more convenient rooms having been obtained in George Street the Council authorized the transfer, and gave orders for the necessary alterations to be carried out. A deputation appointed by the Council to visit Edinburgh on the occasion of the examination in September, expressed great satisfaction with the arrangements made for conducting the examinations.

At the close of November, the Registrar published a list of 390 names and addresses which had been found incorrect, and he gave notice he should erase them from the Register of Pharmaceutical Chemists and Chemists and Druggists, unless the persons referred to communicated with him before the 31st December, 1874. This is the second time since the passing of the Pharmacy Act, 1868, that the Registrar has found it advisable to publish such a list. On the first occasion, in 1872, about 25 per cent. of the persons concerned communicated with the Registrar in time to save the erasure of their names; on the present occasion the proportion doing so is under 20 per cent. Although this is an improvement, there is yet ground for complaint that so many persons should involve the Society in the trouble and expense of at least two registered letters to each, and for regret that no provision has been made for stimulating their attention to their own affairs by a pecuniary goad.

The effort to place pharmacy in Ireland on a more satisfactory footing, to which we alluded last year, has been developed considerably, mainly through the introduction into the House of Commons, in June last, by Mr. ERRINGTON, on behalf of the King and Queen's College of Physicians of Ireland, of a Bill which proposed a simple extension of the Pharmacy Act of 1868 to Ireland. This event put an abrupt termination to the long-pending negotiation between the Apothecaries' Hall of Ireland and the United Society of Chemists and Druggists of Ireland, and for a time at least they acted in accord in opposing the Bill before the Select Committee to which it was referred. Strange as it may seem, the Pharmaceutical Society of Great Britain, which would have been called upon to carry out the provisions of the Bill had it passed, was not consulted in this matter, and there was barely time given for the provision of the evidence of two members of the Council, upon their own authority, as to the working of the Pharmacy Act in England and Scotland. The tendency of the largest portion of the evidence,—including some most astounding statements,—was to the effect that it was advisable to establish a separate Pharmaceutical Society for Ireland, exercising reciprocal rights with the Society in Great Britain, and the Committee reported to the House accordingly. There was a charmingly childish faith manifested in the evidence of some of the witnesses, which appeared to lift them above financial considerations, and reminded one strongly of Mr. HORACE SKIMPOLE; one witness, however, naïvely confessed that the object being *pro bono publico*, he thought a grant might be made from the public funds. Should this plan be adopted, upon the principle that "what is sauce for the goose is sauce for the gander," the Pharmaceutical Society of Great Britain might claim to be reimbursed an amount of expenditure "for the public good" during thirty years that would well justify Mr. SCHACHT in re-introducing his proposal for the establishment of scholarships without any fear of being met by objections as to want of funds. Since the issue of the report, a communication has been received by the Council of the Pharmaceutical Society from the Chemists and Druggists' Association of Ireland, on the subject of extending the Pharmacy Act to that country, and at its meeting in October the Council passed a resolution to the effect that such a course was desirable offering its co-operation in framing a measure, and appointing as a Committee to act in the matter, the President and Vice-President, and Messrs. BETTY, BROWN, GREENISH, HAMPSON and SANDFORD. It is probable, however, that an attempt will be made next session to legislate in the sense of the Select Committee's report.

In April a Juries Bill, containing a provision extending to Registered Chemists and Druggists the exemption from Jury service now enjoyed by pharmaceutical chemists, was once more introduced into the House of Commons. But, as in former years, after repeated postponements, the Bill was crowded out by more urgent—or more clamourous—legislation. Whilst the Bill was before the House, however, the Secretary of the North British Branch of the Pharmaceutical Society, Mr. Mackay, obtained promises from the Lord-Advocate, Earl Dalkeith, and Mr. Duncan M'Laren, that they would endeavour to secure the extension to Scotland of whatever rule might be adopted respecting the exemption from jury service of chemists and druggists in England.

The growing dissatisfaction and distrust with which the operation of the Adulteration of Food Acts has been regarded by tradesmen in general has been shared by pharmacists also. This feeling did not necessarily arise, as has been assumed in some quarters, from a fear of being disturbed in a career of sophistication; for it was due at least as much to the uncertainty as to what might be held to be an adulteration by analysts and magistrates. Therefore the appointment in May of a Select Committee of the House of Commons to inquire into the working of the Acts was welcomed, and care was taken by the Council of the Pharmaceutical Society that the difficulties and dangers to which pharmacists are peculiarly liable under the Acts should be represented to the Committee. The Report of this Committee recognized that although the Act of 1872 had accomplished much good, it had at the same time "inflicted considerable injury and imposed heavy and undeserved penalties upon some respectable tradesmen." This result was attributed mainly to the want of a clear understanding as to what does and what does not constitute adulteration; and in some cases to the conflicting decisions and inexperience of analysts. The construction of the Act upon which was based the decision of the Court of Queen's Bench that the facing of tea is an adulteration, the spirit of which ruling has been followed by magistrates in many subsequent cases, was considered by the Committee as defective, and it recommended that a "fairly faced tea" should not be condemned as an adulterated article. The Committee forbore from recommending that a "certain percentage should be allowed for colouring matters and *impurities* in tea," not because it disapproved of an allowance being made—on the contrary, it considered this advisable—but because it was thought impolitic to set up what might become a standard of depreciation. However it is evident that legislation in this spirit is a *sine quâ non* to pharmacists, to relieve them from danger of prosecution for the presence of a reasonable amount of impurities which are in some cases inseparable from their wares. Another recommendation of the Committee was that the sale of mixed articles of food, such as cocoa and mustard condiments, should be allowed, provided the fact of the article being a mixture were indicated by a conspicuous and legible label; a verbal declaration was considered impracticable. With respect to the chief cause, according to the Committee, of the cases of hardship in carrying out the Act, little was contributed in the Report towards defining adulteration, and that little had reference rather to what should not than to what should be deemed an adulteration. The evils resulting from conflicting evidence of analysts, however, it was suggested, might be remedied by the formation of a board of reference to which magistrates might turn for trustworthy and impartial advice, and, speaking confessedly upon imperfect information, the Committee pointed to the Laboratory at Somerset House as available. The idea of a Board of Reference has been received with considerable satisfaction; but the proposition that the Chemists to the Inland Revenue Board should act in this capacity has evoked much opposition. Suggestions on this point have differed widely: from a single Board sitting in London to ten or a dozen Boards distributed through the country; and from the referees being all nominated by the Government to their being elected by the public analysts themselves. There can be little doubt that in order to gain general confidence such a Board should include those who might be deemed representative both of the public and of the public analysts. By the formation of the Society of Public Analysts a coherence has been given to the latter body which it did not possess at the time of the issue of the Committee's Report, but which would probably enable it to influence materially any attempt to legislate on the snbject. This new Society has devoted its maiden efforts to the defining of adulteration; but at present it has not got further than a tentative description of an adulterated article. A most gratifying circumstance connected with this subject has been the widening recognition—as evidenced by appointments—of the peculiar fitness of pharmaceutical chemists for the office of public analyst; and although the Pharmaceutical Society cannot be expected to adopt the advice of a medical contemporary and specially occupy itself with the work of providing suitable men for this new office, there is little doubt that the desired result is incidentally obtained by the Society's efforts to heighten the standard of pharmaceutical education.

Although the Act has been somewhat in abeyance since the issue of the Committee's report, the prosecutions and convictions during the year have nevertheless been very numerous. Amongst those recorded in this Journal the following present points of special interest to the chemist and druggist:—Conviction of a druggist for selling mustard containing flour, on the grounds that its efficacy as a drug was thus impaired; three prosecutions for the sale of sulphur containing varying quantities of gypsum, the first being abandoned because the preparation had been sold as "milk of sulphur," the others resulting in convictions, because the preparation had been sold as "precipitated sulphur;" a prosecution for selling citrate of iron and quinine adulterated with cinchonine and quinidine, dismissed because of the small proportion of alleged adulterants and their possible origin from the same source as the quinine; a conviction for selling quinine largely adulterated with sulphate of cinchonine; two convictions for the sale of scammony containing in one case only 46·01, and in the other 47·96 per cent. of resin; a prosecution for selling scammony alleged to contain 5 per cent. of flour and 3 per cent. of chalk, but admitted to contain upwards of 70 per cent. of resin, which was dismissed and led to the abandonment of other prosecutions that had been initiated; a prosecution for the sale of red precipitate alleged to contain 5 per cent. of oxide of lead, which was dismissed, but defendant ordered to pay costs; a prosecution for the sale of soda-water devoid of soda, which was dismissed, but a case was granted; a conviction for sale of lemonade containing lead; and prosecutions for the sale of preserved vegetables containing copper, and vinegar containing sulphuric acid. Amongst the curiosities of analytical prosecutions may be recorded one for selling "conversation lozenges" containing one-ten-thousandth part of powdered glass, and one-tenth of starch, and another for selling "burnt almonds" containing too large a proportion of bitter almonds. Another conviction was for selling a "liquid extract of beef," described as consisting chiefly of extract of beef, wine, a small quantity of fine old brandy and quinine, but which the analyst certified to contain but a very minute quantity of beef, no quinine, and no brandy. Early in the year Mr. J. Mackay, of Edinburgh, brought forward a case in which a firm of analysts certified that some Natal arrowroot taken from an original package contained from 10 to 20 per cent. of torrefied arrowroot or other starch, a statement that was flatly contradicted by four other eminent analysts to whom samples were submitted. In this case the mistake only resulted in the annoyance of having the package returned by the customer as adulterated; but in July a prosecution was commenced for selling arrowroot that was certified by a public analyst to be adulterated with another starch, which was dismissed by the Bench acting upon a certificate of Dr. Voelcker that the arrowroot was pure. Another case of adulteration that has been before a law court, though not under the Adulteration Act, was in respect to a sale of adulterated musk pods. We had occasion also to mention a few months since that a large parcel of "sulphate of quinine" had been offered for sale at a low price on the plea that it contained a trifling percentage of cinchonidine, but which on examination proved to contain 60 per cent. of sulphate of cinchonidine.

One result of the increased attention directed to the subject of the purity of food and drugs has been an enormous increase in what may be called the "literature of adulteration," a large proportion of which has appeared in these pages. Amongst others may be mentioned the articles on Milk by Dr. Voelcker and Dr. Macadam; Mr. Wanklyn's books on Milk Analysis, and Tea, Coffee, and Cocoa Analysis; Mr. Wigner's paper on the Ash and Extract of Teas; Mr. Greenish's paper on Scammony Starch; M. Mene's data for detecting an admixture of Japan Wax with beeswax; M. Cazeneuve's micro-chemical examination of Angustura bark; Mr. Horsley's description of a new lactometer, and Mr. Stoddart's application of it to the analysis of butter; Mr. Cleaver's method for the detection of alum in bread, and his experiments upon the decomposition of milk by keeping; Dr. Atcherley's Adulteration of Food, with Short Processes for their Detection; and Dr. Hassall's article on Mustard and its Adulterations. Amongst the adulterations, substitutions or impurities that have been noted are, an opium of good appearance that yielded less than 3 per cent. of morphia (Mr. B. S. Proctor); a specimen of opium containing a lump of earth equal to 10 per cent. of its weight (Mr. Gostling); a falsification of cinchona bark by the external saturation of a comparatively worthless bark (M. Bernatzik); the substitution of the stem of Pareira Brava (*Chondodendron tomentosum*) for the root (Mr. J. Moss); the substitution for Chiretta of another species of *Ophelia* (Professor Bentley); the bleaching of ginger by coating it with from 2 to 3 per cent. of whitewash (Mr. Garside); the adulteration of opoponax with other aromatic gum resins (M. Marais); the general substitution of other starches for the wheat starch o the Pharmacopœia (Mr. Abraham); the adulteration of ipecacuanha powder with almond meal (Mr. Mercer); the occurrence of sulphuric acid in tartaric acid; and the adulteration of "putty powder" with oxide of lead (Mr. Wellborn). In consequence of the vagueness of the assertions commonly made respecting the use of cocculus indicus in the adulteration of beer, an attempt was made to collect some information upon the subject, but although the question provoked several replies, no satisfactory evidence of the berries being so used was forthcoming, a result which is in accord with the failure of the chemists at Somerset House to detect the presence of this adulterant in any of the numerous samples of malt liquor constantly examined by them.

We have thus devoted a considerable space to the subject of adulteration, but as we believe that it is one that is likely to become of peculiar interest to pharmaceutists we hope that the collation of this information here will not be deemed out of place.

The foregoing failures to legislate may be supplemented by the mention of an Act, not without interest to chemists, that was passed, namely, the Alkali Act Amendment Act. This important Act defines "alkali work" so as to include works in which copper ore is treated with common salt; restricts the escape of muriatic acid gas to one-fifth of a grain per cubic foot of other gases leaving the works; and includes amongst noxious gases subject to the operation of the Act, sulphuric acid, sulphurous acid (except that arising from the combustion of coals), nitric acid and other noxious oxides of nitrogen, sulphuretted hydrogen, and chlorine.

Another subject that has engaged the attention of Parliament is Co-operative Trading, especially that phase of it in which the business has been principally conducted by civil servants of the Crown. In a temperate speech Sir THOMAS CHAMBERS urged before the House of Commons various objections to this practice, especially instancing the dispensing of drugs, and asked for an assurance that it had not the sanction and approval of the Government. Premising that the subject was a difficult one, the Chancellor of the Exchequer only promised that it should have the careful consideration of the Government. During the year numerous communications to this journal respecting Co-operative Trading have been received; but although as a rule it has been thought not advisable to publish them, the writers may feel assured that this has not occurred through undervaluation of their importance.

The Excessive Hours of Labour in Pharmacy have been the subject of many letters and more than one editorial article, but at present with only very partial effects. Still, as it will be something gained to familiarize pharmacists with the idea that at some future time they may limit business within the same hours as other tradesmen, it is proposed to revert to the topic at every convenient opportunity. The subjects of the charges made for medicines, the prices charged for proprietary articles, the practice of allowing percentages, and the kindred one of using obscure formulæ, have all been discussed, and to the latter we are indebted for introduction to an interesting couple in Mr. PIL PHILIP and Miss COMP. In January a new Scale of Medicines and Medical Stores to be carried by Merchant Ships was issued by the Board of Trade.

The number of deaths from poisoning recorded in this Journal during the year has been 46,—or five more than last year,—the majority of which were suicides. The details are—opium, 1; morphia, 3 (in one case dispensed in mistake for pepsin); laudanum, 1; strychnia, 3; vermin killer, 2; oxalic acid, 2; phosphorus, 1; prussic acid, 3; chloral, 1; chloroform, 1; chlorodyne, 1; arsenic, 6; lotion, 1; liniments, 3 (taken in mistake for medicine); ointment, 1; carbolic acid, 6 (in five cases taken instead of medicine); sulphuric acid, 2; spirit of salt, 1; oxalic acid, 2; hellebore, 1; teething powders, 4. The small number of deaths from vermin killer again testifies to the wisdom of including them in the poison schedule.

Six prosecutions under the Pharmacy Act, 1868, have taken place during the year. The first summons was taken out by the police against a chemist and druggist for selling a packet of vermin killer without registering the sale; of the other cases, in which the Pharmaceutical Society was the prosecutor, one was for the use of the name "druggist" by an unregistered person; one for the sale of a "vermin killer" at Stradbrooke, Suffolk, by an unregistered person; one for the sale of oxalic acid in Clerkenwell by an unregistered person, who was afterwards summoned for keeping open shop for retailing, dispensing, or compounding poisons; and one for the sale at Woburn of prussic acid without labelling with name and address. The last was virtually a prosecution of an unregistered person for dispensing a prescription containing a poison within the meaning of the Pharmacy Act. In all these cases penalties were recovered.

During the year several other cases, besides the Adulteration cases already mentioned, interesting to chemists and druggists, that have been before the law courts, have been recorded in this Journal. The case of *Hunter* v. *Freeland*, where the defendant suffered heavy pecuniary loss through the accident of his apprentice; the committal of a chemist and druggist for trial on a charge of manslaughter at the Devon assizes, where the Grand Jury ignored the Bill; some charges of fraudulently imitating labels, and the still-pending Excise prosecution for the sale of "morning cordial" at Hull, are amongst the most important. We are informed that the hearing of this case is fixed for the 15th January.

The meeting of the British Pharmaceutical Conference this year was so far exceptional that it having been thought impolitic to accompany the British Association to Belfast, the opportunity was taken to hold it in London and—upon the invitation of the Council—in the premises of the Pharmaceutical Society. The meeting, which was inaugurated by a Conversazione, was marked by the election of a large number of members, but was not nearly so well attended as might have been expected. Mr. T. B. GROVES's Presidential Address, which was confined to purely political topics, was followed by the reading of twenty-eight papers, of a nature well qualified to keep up the reputation of the Conference. These papers are noticed in another column. There were the usual social accompaniments of a dinner and an excursion, and the arrangements throughout were admirably made and carried out. There was also an Exhibition of objects relating to pharmacy. The Conference is to meet next year at Bristol, again under the presidency of Mr. GROVES.

The Fourth International Pharmaceutical Congress was held in August at St. Petersburg, and was attended by Messrs. SUTTON and GREENISH on behalf of the Pharmaceutical Society of Great Britain. Although the subjects discussed, with the exception of the International Pharmacopœia, were generally those which primarily affect continental pharmacists, there can be little doubt that the Council acted wisely in securing the utterance of British opinions even upon these, and the satisfaction which their action gave to continental pharmacists has been marked by the conferring of the Honorary Membership of different societies upon the delegates. An interesting report was presented to the Council by the delegates in October, and its reading was followed by the passing of an unanimous resolution inviting the Congress to hold its next meeting in London.

The British Association held a successful meeting in Belfast, presided over by Professor TYNDALL. The eloquent address of the President provoked more than an usual amount of protest from those who assume to be orthodox; indeed, the Professor himself has since appeared to shrink from the inferences drawn from some of his sentences. Another notable feature of the meeting was Dr. HOOKER'S paper on Carnivorous Plants. The meeting of the British Medical Association, at Norwich, was also a success, and the Centenary of the discovery of oxygen by PRIESTLEY was the occasion of interesting meetings at Birmingham, in England, and Northumberland, in the United States. The annual meeting of the Royal Society was made more than usually noteworthy to pharmaceutical chemists, by the placing of the names of two more members of their body on the Roll of Fellows, those of Mr. H. B. BRADY, and Mr. J. E. HOWARD.

In March the issue of a reprint of the British Pharmacopœia furnished the opportunity of appending some "Additions," which were also published in a separate form. The "Additions" included thirty-four items and formed the subject of an elaborate review and criticism by Mr. CHARLES UMNEY at one of the evening meetings. The presence of some and the absence of other preparations, and some of the formulæ, provoked a considerable amount of rather sharp criticism, but on the whole the addendum was ably defended by its editor, Professor REDWOOD. There was a considerable manifestation of opinion, however, that it is unsatisfactory that pharmacists should have no legal right to take part in a work for which they are so peculiarly fitted as the preparation of a national pharmacopœia. In July this part of the subject was brought before the Council of the Pharmaceutical Society, by Mr. HAMPSON, and after discussion a resolution was passed respectfully urging upon the General Medical Council the desirability of associating more practical pharmacists with any Committee which may be appointed for the purpose of preparing a future edition of the British Pharmacopœia or any further additions to the present one. The resolution was forwarded to the Medical Council and read at its meeting in July, but no motion was made respecting it, and a series of resolutions presented by Dr. A. SMITH, including some suggestions in the same direction, had previously fallen through by want of a seconder.

The wide subject of an International Pharmacopœia has also attracted some attention from having been under the consideration of the International Pharmaceutical Congress at St. Petersburg. A scheme which had been drawn up by a Committee of the Paris Société de Pharmacie was received and entrusted to various delegates to report upon. In the meantime, it was resolved that it is desirable an International Pharmacopœia should be formed, and certain principles were adopted as recommendations to any commission that might at some future time be entrusted with that work, as also for adoption in compiling national pharmacopœias. As to the nomenclature an expression of opinion from the different societies was solicited. The subject was therefore brought before the Pharmaceutical Society of Great Britain, at an evening meeting, by Mr. GREENISH and Professor ATTFIELD. Though no formal resolution was then adopted, the preponderance of the opinion expressed was in favour of the system of nomenclature advocated by Professor ATTFIELD and already adopted in the United States Pharmacopœia. Mr. INCE'S recent paper on a uniform method of expressing spirit strength is also a contribution towards uniformity.

Although the construction of an International Pharmacopœia, including all the Continental States, is probably yet somewhat remote, a suggestion which has been made for the construction of a Pharmacopœia for Great Britain and the United States deserves serious consideration, especially on account of the position of our Canadian brethren, who are supposed to be guided by the British Pharmacopœia, but largely follow that of the United States. The *Tennessee Pharmacal Gazette*, commenting on the proposition, says, "Our Pharmacopœia needs a revision badly, and from the criticisms brought out by the recent British Addendum we were induced to believe a revision of the British Pharmacopœia, if properly conducted by practical pharmacists, would be very popular in England. The necessity for an Anglo-American Pharmacopœia is admitted by all, and we hope to see the good work commenced at once."

In technical pharmaceutical literature the most prominent place has been taken this year by cinchona products, little having been heard of trimethylamine, to which that position was assigned last year, except that it could be prepared from the skate. A most important fact is the confirmation of the very large alkaloidal yield,—principally quinine,—of the bark of what is at present known as *Cinchona Calisaya*, var. *Ledgeriana*, a confirmation practically manifested at a sale in Amsterdam, where a parcel of it realized about three times the average price given for other Calisayas offered at the same time. It would appear from Dr. HESSE'S recent article that, upon chemical grounds, he is inclined to think that the plant now associated with Mr. LEDGER'S name is the true Calisaya, and that the plant grown for so many years under that name really belongs to another species. This is vehemently disputed by Dr. DE VRIJ, and until these doughty combatants have spoken their last word it would almost be presumption to express any opinion as to which is right. A recommendation to adopt the plan of coppicing cinchonas led Mr. HOWARD to express his opinion that the result would be a bark rich in astringent substances and useful as a tonic, but not rich in quinine, on the ground that the alkaloids are not formed in the leaves and carried downward by the descending sap, but in the cellular tissue of the bark. Mr. Howard has also described what is probably a hybrid between *C. Calisaya* and *C. succirubra*, which not only presents externally characteristics of both its presumed progenitors, but also in something like equal proportions, their alkaloidal properties. Although the plants were sent to England as a variety of Calisaya, the bark yielded a large quantity of cinchonine, which latter is almost, if not quite, absent from true Calisaya, and, moreover, yielded Hesse's new alkaloid, quinamine, which previously had only been observed in bark from East India growth *C. succirubra*. The importance of this observation as indicating that degeneration is consequent upon hybridization is obvious. It is announced that the experiment of cinchona cultivation is to be resumed in the island of St. Helena; and the rather startling yield of 14 per cent. of quinine by a bark from the isle of Reunion is reported last week in the *Lancet* as a "good beginning," but we confess we have failed to find authority for more than one-tenth of that quantity. The appearance of Dr. Hesse's exhaustive history of the cinchona alkaloids will help to clear up the confusion respecting them, and with the exception of the use of the name conchinine for Pasteur's quinidine, will probably be generally received as authoritative. The alkaloids which he considers have been proved to be obtained from cinchona barks are seven in number—quinine, cinchonidine, cinchonine, paricine, quinamine, paytine, and conchinine (=quinidine). Dr. Hesse has also pointed out pure chloroform as an excellent separatant of the sulphates of the principal cinchona alkaloids. Dr. Weidel has described four crystallizable acids obtained as oxidation products of cinchonine, and he has traced their analogy with oxidation products from other substances. Further, Herr Bauer has described a series of compounds of iodine with the cinchona and other alkaloids. In a valuable paper read before the Conference, Dr. De Vrij contributed some tests for estimating the value of barks for pharmaceutical purposes, and in the discussion which followed comment was made upon the anomaly that only the American grown barks are official. Dr. De Vrij further expressed the opinion that the only form in which cinchona ought to be prescribed was as an alcoholic extract, and Mr. Broughton testified to the use in India of the whole of the alkaloids precipitated together. In other contributions to the pharmacy of cinchona Mr. Brown has shown that heat is unnecessary in the preparation of Tinct. Quiniæ Ammoniata; a solution of lactate of quinine has been recommended as most suitable for hypodermic injection; a neutral hydrobromate of quinine (soluble in five times its weight of water) has been recommended by M. Boille as greatly superior to all other compounds of quinine; and tartaric acid and glycerine have been indicated as forming a good pill excipient for sulphate of quinine.

Boldo, the leaves of a Monimiaceous plant growing in the Chilian Andes, has attracted some attention as a new remedy for liver complaints, and as a useful tonic in cases where quinine is unsuitable. The action of the drug appears to be mainly due to an essential oil which is abundant in the leaves of the American plant, but was not developed in a plant grown in Paris. Little is known yet of the real value of this substance as a remedy, but its pharmacy has been worked out by M. Verne.

In Jaborandi, however, of which the origin is not yet cleared up, we have what promises to be a valuable addition to the materia medica, since it is undoubtedly a powerful sudorific and sialogogue. The drug was first brought under the notice of the French faculty by Dr. Coutinho, and the experiments with it have been repeated in University College Hospital, and described by Mr. Martindale. The specimens hitherto received have been so fragmentary that its botanical origin is uncertain, and whilst Professor Baillon looks upon it as a Rutaceous plant, others consider it to be one of the numerous Pipers for which Jaborandi is a generic term in South America.

Eucalyptus globulus is another plant which has elicited diverse opinions during the year; for whilst it has been asserted that its antimalarial influence has been established by experiment in Algeria and elsewhere, and Mr. Bosisto has asserted that the whole atmosphere of Australia is beneficially influenced by the exhalations from eucalypti, an English Secretary of State has expressed his opinion that its effects have been greatly exaggerated. This plant furnished the subject of an able lecture by Professor Bentley at the Royal Botanic Gardens. The essential oil has recently been recommended as a vermifuge.

Still another plant which has been mentioned as a new—or rather recovered—remedy, is the "driâs," attributed to the *Thapsia Silphium*, of Vivani, and considered by some to yield the famous silphium of the ancients. A considerable quantity of this plant is reported to have been collected in the Cyrenaica and shipped to France, and there used with considerable success. The claim of *Rhamnus Frangula* bark to a place in the Pharmacopœia was again urged by Mr. Baildon, at the meeting of the British Pharmaceutical Conference, on which occasion its value as a mild but effectual aperient was testified to by several speakers, and a concentrated decoction recommended as the most convenient form of administration. The root bark of *Ailanthus glandulosa*, Desf., has been mentioned as a remedy used in dysentery in China and Japan, and a vegetable vesicant used in Africa, according to Dr. Schweinfurth, is the *Adenia venenata*, a climbing passion flower. Mr. Henry Groves has given an laborate description of the popular remedies of the Tuscans. The uses of *Geranium maculatum* for dysentery, *Gerardia quercifolia*, Pursh., as an antidote to snake bite, trompatilla (*Bouvardia jacquini*, H. B. K.), for hydrophobia, and an infusion of the branches of *Verbena bracteosa*, Mich., in the treatment of scrofulous affections, have been mentioned by Professor MAISCH, and Mr. STACEY has described some remedies used by the North American Indians. The use of *Gelsemium sempervirens*, which is official in the United States Pharmacopœia, has extended to this country and has been recommended by Dr. SAWYER, of Birmingham, for the relief of neuralgic pains in the face and jaws. The anti-scorbutic properties of the *Agave Americana* have also been described, and Dr. DE VRIJ has referred to the value of pomegranate root bark as an anthelmintic.

The acclimatization of ipecacuanha in India may now be looked upon as an established fact, as many as 63,000 living plants being in existence there at the date of the last report. An interesting experiment has also been made to acclimatize the tea plant in Anjou. The successful application of sewage in the cultivation of labiate plants is reported from the neighbourhood of Paris, and a suggestion has been made that in the cultivation of these and similar plants railway embankments might be profitably utilized. The increasing use of vanilla has justified the reproduction of information respecting its cultivation, as well as that of the so-called wild vanilla (*Liatris odoratissima*). One of the most notable chemical exploits of the year has been the preparation of vanillin, the odorous principle of vanilla, from pine juice, by Messrs. TIEMANN and HAARMAN, a discovery that has already been turned to industrial account. It may be mentioned here that a number of cases of suspected poisoning through eating vanilla ice have occurred in Vienna. The collection of gamboge was the subject of an interesting communication from Mr. JAMIE, of Singapore, to the North British Branch of the Pharmaceutical Society. In answer to numerous queries our pages have been supplied with ample directions for the preparation of herbaria of both land and water plants.

A further investigation of the chemistry of the Aconites formed the subject of a contribution from Mr. GROVES to the Conference meeting. His principal result was the determination that aconitine, pseudaconitine, and another, and probably new, bitter body are polymerides, a remarkable circumstance being that the latter is inert. Some experiments of ZINOFFSKY upon different species of *Aconitum* appear to show that the flowers are always richer in alkaloids than the leaves or stalks. Aloin has been the subject of some researches which have led Dr. SOMMARUGA to the conclusion that the aloins from Barbadoes, Natal, and Socotrine aloes may be represented by formulæ differing by one and two atom groups of CH_2 respectively. In a like manner Professor FLUCKIGER is of opinion that the constituents of elemi are an essential oil, a crystallized resin, an amorphous resin (?), and bryoidin, constituted by $C_{10}H_{16}$, and progressive proportions of H_2O. Professor FLUCKIGER has also found that the crystalline matter separating from oil of nutmegs, and sometimes called myristicin, is myristic acid. He has also pointed out some peculiar characteristics in the histology of buchu leaves. Professor SPIRGATIS has found that scammonin prepared from the root of *Convolvulus Scammonia*, and that obtained from Aleppo scammony, are identical in composition. A curious toxical property possessed by the colchicum plant at the time of flowering has been pointed out, and a remarkable case of poisoning by colchicum wine has heen reported from Canada. The occurrence of nitrate of potash in some plants has been noticed on various occasions, and its presence in considerable quantity in *Ricinus communis* has been recognized by Professor WAYNE. M. CARLES has come to the conclusion that the acid of balsam of tolu is pure cinnamic acid. Mr. POWER has found that the podophyllum rhizome is almost entirely exhausted of its cathartic properties by percolation with alcohol; also that the portion of the resin soluble in ether is much more active than that which is insoluble. Mr. JUDGE states that sarsaparilla is not injured medicinally by the heat of a water bath, and Mr. BARTON recommends the use of more spirit in preparing the liquid extract. Coca (*Erythroxylon Coca*) has been considered pharmaceutically by Mr. SHUTTLEWORTH, and formulæ for different preparations given, and a similar service has been performed for guarana by Mr. MOORE.

Experiments made by different observers confirm the fact that ammonia is absorbed by the aerial portions of plants, although the plants do not appear to thrive when access of ammonia to the roots is prevented. Further, Professor GABBA states that some remarkable changes in the colour of flowers take place under the influence of ammonia, and that asters acquire a pleasant odour after exposure to its fumes. M. TRUCHOT has been testing the proportion of ammonia present in the air at different heights, and finds that it varies inversely as that of carbonic acid. It has been supposed that ozone is formed during the oxidation of essential oils, and the alleged antimalarial properties of scented flowers have sometimes been so explained. But Mr. KINGZETT is of opinion that the active agent produced by the oxidation of essential oils is a monohydrated oxide of turpentine ($C_{10}H_{16}O.H_2O$). M. VOGEL has founed water containing oil of turpentine to accelerate the germinative process in plants, and a still more stimulative action to be exercised by camphor. The motions of camphor and other substances upon water have been described and explained by Professor TOMLINSON, and a kindred subject, "cohesion figures," as a means of detecting adulteration, has been revived by a lady pharmacist in America.

Some valuable contributions to our knowledge of the camphors have been made during the year. The history of Ngai camphor by Mr. Hanbury led up to its chemical description by Mr. Plowman, who reported that he found it to be isomeric with Borneo camphor, and this was followed by Mr. J. Moss's suggestion that it might bear the same optical relation to Borneo camphor as feverfew camphor does to laurel camphor; this was subsequently confirmed by Professor Fluckiger. Monobromated camphor, formed by the substitution of an atom of bromine for one of the atoms of hydrogen in camphor, is coming into considerable repute as a sedative, but its limited solubility presents a great difficulty in dispensing. Its preparation has been recently described by M. Gault. The beautiful camphor which separates from Japanese oil of peppermint, and is known under the name of crystallized oil of peppermint, has also been brought under the notice of the Pharmaceutical Society, at an evening meeting, by Mr. Moss. The colouration which takes place when chloral hydrate is shaken with oil of peppermint is attributed by M. Frebault to the action of free acid contained in the chloral hydrate upon the colouring matters in the oil of peppermint. He also describes a series of similar reactions upon the addition of different acids to the oil, and points out a curious analogy between the behaviour of the green matter so produced and that of chlorophyll. M. Roucher has also called attention to a marked dichroism which occurs upon the addition of acetic acid to oil of peppermint. Mr. Horner has called attention to the fluorescence in castor oil of several bodies that are not fluorescent when dissolved in water.

The rectification of alcohol by means of lime has been the subject of an examination by Mr. Bullock, who finds that the first portions passing over are not so rich in alcohol as some later ones, which he attributes either to lime having an affinity for the stronger portion of the alcohol, or to water more freely vaporizing in an atmosphere of alcohol vapour. A curious instance of the conversion of alcohol into acetate of ethyl by the agency of cryptogamic life has been reported by Mr. Rimmington, and the presence of a fungus in a decomposed lozenge has been the subject of a paper by Mr. Greenish. M. Pasteur has described the preparation of an unalterable beer by using a pure yeast free from foreign fermentative agents, these having less power to set up changes after the beer has once been made. Mr. Horace Brown has come to the conclusion that fermentation is remarkably retarded by diminished atmospheric pressure. Further, the action of bromine upon various alcohols has been studied by M. Hardy.

The high reputation which chloral hydrate has attained as a medicinal agent shows no sign of waning. The importance of using it pure and the hurtful nature of its decomposition products were, early in the year, pointed out by Dr. Leibreich, who expressed a preference for the crystalline form as the most stable, and this is the form now made official in the B. P. Various reactions of chloral have been described; also its power of combining with albumenoid matters, and so arresting decomposition, and its singular property of liquefying when brought into contact with camphor; further, it has been recommended for external application. Its caustic action has suggested its use in that direction by the surgeon, and pencils prepared from metachloral, an isomeric modification of anhydrous chloral, have given a like satisfactory result. The solvent action of chloral hydrate upon different alkaloids has opened up another sphere of usefulness for it. A case in which a man recovered after swallowing six drachms of chloral hydrate, and remaining insensible during thirty-two hours, has been reported from Wiesbaden.

The great increase in the medicinal exhibition of phosphorus has given scope for much ingenuity in the pharmaceutical manipulation of this element. Mr. Gerrard's suggestion to dissolve it in resin was varied by Mr. Abraham's to use balsam of tolu, and the latter was adopted in the new Pilula Phosphori of the Additions, wax being added to make a suitable mass. Criticism of the latter formula induced Professor Redwood to mention soap as a suitable excipient; he has also given a formula for the administration of the Oleum Phosphoratum as an emulsion. Mr. Williams brought before the notice of the Conference a solution of phosphorus in alcohol and glycerine. Mr. Ashburton Thompson has given a formula for a "tincture" of phosphorus, and of course America has provided an "elixir." Mr. Postans has done useful service by suggesting the possibility of using phosphorus in its more convenient amorphous condition, and experiments in this direction are very desirable. The various syrups of phosphorus, existing as phosphate, lacto-phosphate, and hypophosphite, and in combination with different bases, have been the subject of many papers, amongst which may be particularly mentioned those of Dr. Polk, Mr. Broad, and Mr. Daniels.

The acknowledged difficulty of keeping a 2 per cent. solution of hydrocyanic acid, as ordered in the Pharmacopœia, without loss of strength, has been discussed in several papers, and the majority of writers have favoured the use of a 0·2 per cent. solution, as suggested by Dr. Tilden, or of the double cyanide of potassium and zinc, as suggested by Mr. Towerzey. Mr. Williams, however, has observed that the addition of glycerine materially increases the stability of solutions of hydrocyanic acid.

Glycerine has also been added to the ever increasing list of substances that promote the extinction of mercury in the preparation of mercurial ointment; it has besides been shown by M. Carles to increase the solubility of lime in water, probably by forming a soluble glycero-calcic compound. At the Vienna exhibition crystals of glycerine were exhibited by Messrs. SARG; and from Professor GODEFFROY of the same city has recently been received a rough but convenient method of testing the purity of glycerine.

A recent paper by Mr. BARNES, calling attention to the preservative influence of chloroform upon vegetable infusions has given rise to some discussion. It may be as well to note that Mr. BARNES did not recommend the addition of chloroform to infusions intended for use in dispensing, as has been rather hastily assumed; he simply placed the fact on record. The discussion has shown that there is no real difficulty in preserving vegetable infusions from decomposition during a considerable time; but we are inclined to hold with Mr. MARTINDALE that it is wiser—pharmaceutically and financially—to encourage the use of the fresh aromatic infusion and with Dr. SYMES to leave the preserved infusions for emergencies.

The discovery of the antiseptic properties of salicylic acid and an economic method of preparing it by Professor KOLBE appear to open up a new chapter in the history of preservative agents, and probably these observations will find ready application in pharmacy. A kindred subject has been discussed in the late Dr. GRACE-CALVERT'S memoir on the influence exerted by certain gases and other bodies upon the preservation of eggs.

Amongst other real contributions to pharmaceutical progress may be mentioned Professor TICHBORNE'S elaborate paper upon the substitution of oleic acid for the varying substance called soap, and Mr. GERRARD'S carefully worked out report on the Pharmacopœia plasters. Mr. GERRARD has also suggested the substitution of caoutchouc and benzol for gutta-percha and chloroform in the formula for charta sinapis. The demand for elegant pharmacy has directed increased attention to the subject of pill coating, instructions for which operation have been given on two or three occasions. With the same object, a number of methods have been suggested of masking the taste of, and rendering palatable cod liver and castor oils; jalap has been enclosed in biscuits, and arsenious acid in granules perlés; iodine has been administered in combination with albumen, phosphate of lime dissolved in aërated water, and extract of meat in an emulsion with almonds, preserved by the addition of glycerine.

The introduction of pepsine into the Pharmacopœia gave rise to considerable criticism of the mode of preparation prescribed, but there is a general agreement that it produces a good article. Mr. PHILLIP'S experiments have led him to think that pepsine may exist in the presence of alcohol, but in a latent state, and that it may become active upon the dilution of the alcohol by the juices of the stomach. Pancreatine and its preparations have been described by Mr. MATTISON. Another derivative from the animal kingdom is kouniss, which has been the subject of a paper by Dr. JAGIELSKI, who is of opinion that cow's milk is an equally good raw material with mare's milk for its preparation. This, however, is disputed by a correspondent writing from Tartary.

We have thus indicated a multitude of subjects of practical interest to pharmacists, and it speaks well for pharmaceutical activity that our space is exhausted long before our list. We must, however, refer to the numerous valuable lectures that have appeared in our columns during the year; for instance, Dr. PETTIGREW'S on the relations of plants and animals to inorganic matter; Dr. ANDREWS' and Dr. WATTS' on ozone, Mr. FIELD'S on paraffin, Dr. ODLING'S on evaporation and diffusion, Dr. HOOKER'S on carnivorous plants, Sir JOHN LUBBOCK'S on wild flowers, and last, but not least, Mr. SCHACHT'S admirable address to the Bristol Association.

Bookmaking is now so popular an occupation that the very number of scientific books issued necessarily remits many to the book-case instead of the "inward digestion" of their proprietors, and in some cases the former is the least injurious position. But the past year has been rich in valuable works. Amongst those most interesting to pharmacists may be mentioned the new editions of Parrish's Pharmacy, Garrod's Materia Medica, the Treasury of Botany, Babington, Fresenius' Quantitative Analysis, and Valentin's Inorganic Chemistry. Schorlemmer's History of the Carbon Compounds is *sui generis*. There have been admirable manuals of Chemistry from CLOWES, MUTER, and ARMSTRONG; and a manual of Botany from BROWN. SOUBEIRAN and THIERSANT have given us the Materia Medica of the Chinese, ANDOUARD the Pharmacy of France, and the BRITISH PHARMACEUTICAL CONFERENCE a Year-book of the Pharmacy of all countries. And, keeping the best wine till last, the date of the publication of HANBURY and FLÜCKIGER'S Pharmacographia should be a red-lettered day in every pharmaceutical bibliophile's calendar.

The year in which Death has robbed English pharmacy of THOMAS NEWBORN ROBERT MORSON and HENRY DEANE, and American pharmacy of WILLIAM PROCTER, must needs be a memorable one. The names of the former are indissolubly connected with the history of the Pharmaceutical Society of Great Britain as active workers in its earlier days, in the Council and Examination Rooms, and in the Presidential Chair, as that of the latter is with the Philadelphia College of Pharmacy. It would be exaggeration to say that their places cannot be worthily filled, but probably many years will pass without taking from pharmacy three men who have done so much for its welfare or honoured it so much by their lives. Other old and valued friends of the English Society have been taken in GEORGE EDWARDS, a former Vice-President, Councillor and Examiner, and THOMAS STANDRING and GEORGE MEGGESON, also former Members of the Council. Still one more bearing a name well known to pharmacists has passed away in

Charles Harley Savory. Chemistry has lost two prominent disciples in Thomas Anderson and Frederick Rochleder; whilst medicine mourns amongst many others Neil Arnott, Forbes Winslow, Edwin Lankester, James Ranald Martin, Edward Smith, Francis Edmund Anstie, and David Livingstone.

Thus we have descanted at considerable length upon a great variety of topics, but all of them, we venture to say, of interest to pharmacists. The works of the Pharmaceutical Society in education, examination, or benevolence; the point at which recent legislation has approached most nearly the pharmaceutical domain; the new articles of the materia medica, and fresh information about old ones; the improvements in pharmaceutical processes and the bearing of the year's chemical research upon pharmacy; and the names of some of the worthies who have departed, have been in succession passed in review: with what result such of our readers who have followed us thus far will perhaps be better able to judge than ourselves. Be this as it may, in the words of Herrick—

> "Of those, and such like things, for shift,
> We send, instead of New Year's Gift.
> Read then, and when your faces shine
> With buxom meat and cap'ring wine,
> Remember us in cups full crown'd,
> And let our city health go round."

On our part we anticipate our kind friends by wishing them a Happy and Prosperous New Year!

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

Fifth general meeting held at the Royal Institution, December 17th, 1874, the president Mr. A. H. Mason, F.C.S., in the chair. After the formal business Mr. Murphy said that pitch had lately been rendered very scarce, in consequence of the great demand for anthracene causing distillers to use so much heat that the residue was useless for such purposes as road-making, coating roofs, &c. He had been informed that pitch from shale oil, and petroleum oil had been tried as substitutes, but found unsuitable.

Mr. Shaw called the attention of members to the fact that 27 chemists and druggists on the register in Liverpool could not be found at the addresses given; he asked those present who were acquainted with any of those persons to inform them of the necessity of sending their correct addresses.

Mr. W. E. Bickerdike, F.C.S., then read a paper on "The Chemistry of the Tar Antiseptics," which it is proposed to print in a future number.

A short discussion took place after the lecture, in which Messrs. Murphy, Davies, and others took part, and the meeting closed with a unanimous vote of thanks to the lecturer.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fourth scientific meeting of the session of this Society was held in Anderson's University, on Wednesday evening, 23rd December. Mr. William Whyte, Vice-President (in the absence of Mr. Currie, President), occupied the chair. There was a good attendance. After the usual preliminary business, John Dougall, Esq., M.D. (Vice-President of the Glasgow Southern Medical Society) was introduced, who delivered a lecture on "Zymotic Poison," (printed at page 524 of this journal). Dr. Dougall was frequently applauded in the course of his lecture, his illustrations being specially interesting, and at the close, on the motion of Mr. Kinnimont, seconded by Mr. Fairlie (Sec.), a hearty vote of thanks was awarded the lecturer.

A Committee was then appointed to confer with some of the leading members of the trade, who, it was reported, were not adhering as strictly as should be to the early closing arrangements.

Mr. William M'Kenzie afterwards proposed that the Council make application for a grant of money from the Pharmaceutical Society. An amendment was made to the effect that the application be delayed for a year, which on being put to the vote was carried by a majority.

Some arrangements were then made for the annual festival, which will take the form of a supper and ball, and is to be held on 3rd February.

Mr. Paul asked if ladies could be admitted as members of the Association, but, as some doubt was expressed on the point he put himself in order by giving notice that at next meeting, he would propose that "Ladies interested in the drug business be admitted as members of the Association." His object being to propose also that a lady chemist and druggist, who desired to become a member, should be admitted.

Mr. J. M. Y. Murdoch will read the next paper at the Assistants' section, on January 6th, and Dr. D. Campbell Black will lecture at the next scientific meeting, on 20th January.

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act.

Absence of Soda and Presence of Lead in Soda Water.

In the Central Police Court, Glasgow, before Bailie Torrens, Mr. Alex. Young assessor — Margaret Carmichael, lemonade and soda water manufacturer, was charged with having sold to the sanitary inspectors a bottle of lemonade adulterated with lead, and a bottle of liquid matter represented to be soda water, but which was found to contain no soda, and to be adulterated with lead. On being asked whether she was guilty, the defender replied that she did not know that the liquids contained lead, but she was aware that the bottle said to be soda water contained no soda. It was just what was sold in Glasgow as soda water, and the customers preferred it. The machine used in manufacturing the drinks had lead pipes, and the receiver was composed of lead. This was taken as a denial of the charge, and the evidence in the case was heard. Dr. Clark, one of the city analysts, deponed that the sample contained 1·2 grains of lead per gallon. It was simply an aqueous solution of carbonic acid. The quantity of lead which it contained was sufficient to prove injurious to health. Many medical men said that less than one-tenth of a grain would prove injurious, and in this sample there were twelve-tenths. Lead was a cumulative poison. It remained in the system after the other ingredients in the liquids had passed off, and if taken daily it would in a month or six weeks produce lead-poisoning. Defender: I have been in the habit of drinking it for three years. Witness continued: In the Campsie case there were only nine-tenths of a grain. Bailie Torrens: I am rather astonished to hear that lead is a cumulative poison; that is left in the system. If that were the case, my apprentices would be dead before half their apprenticeship was out. The Procurator-Fiscal (Mr. Lang): They don't swallow lead. Bailie Torrens: But they inhale it. The Procurator-Fiscal: If you have any doubt I will produce authorities. The witness further stated that the British Pharmacopœia gave as the proper constituents of soda water 30 grains of bicarbonate of soda in a pint of water. For the defence, the defender called the manager of her establishment, who stated that the liquid represented to be soda water was that usually sold under that name, and that it was preferred by customers. He believed the lead came off the pipes of the machine, and defender had given orders that it should not be used more until altered. The Court found the charge proven, and defender was fined £3 3s., with £1 7s. expenses.

James Murdoch, soda water dealer, 7½ Nicolson Street, was next charged with having sold as unadulterated a bottle labelled as containing soda water which was adulterated with lead or other substance. Defender, on being asked to plead, admitted that he sold the liquid, declaring at the same time that it was as respectable a bottle as had passed through his hands for the last 20 years. Mr. Walker, the sanitary inspector, deponed that when he purchased the bottle Murdoch told him that it contained no soda—simply carbonic acid gas and water. As he was leaving, he told him further that it passed through lead pipes and a lead reservoir, and that there was likely a little lead in it. He did not say this at first. Dr. Clark deponed that the sample contained 1·1 grain of lead per gallon. Dr. J. B. Russell was next called, and deponed that if lead was found in soda water in the proportion of 11-10ths of a grain per gallon, it would certainly prove injurious to health. Parkes said that 100th of a grain per gallon was injurious to health. If a person in robust health were taking a bottle, or two bottles per day for a week of soda water, containing 11-10th grains of lead, it would likely result in a bad case of lead poisoning. Defender wished to know whether Dr. Russell had ever been an aërated water manufacturer, and whether he knew anything of raising a float; but Dr. Russell had to confess that he did not. Defender, who had repeatedly interrupted the witnesses, was then heard in his own defence. He denied that lead was a poison, and characterised the allegation as a humbug. He had been twenty-two years a dealer in soda water, and if it would be any satisfaction to the public, he would sup porridge made of the water he sold, and take the remainder in soup for his dinner. At his request Dr. Clark was recalled, and stated that the quantity of lead in the sample would not be the size of a pin head, whereupon the defender declared his readiness to consume a piece of lead the size of his finger, either whole or in solution. The magistrate took a different view. Men who had studied the subject considered, he said, that lead was a poison; and he must, therefore, impose a penalty of £3 3s., and £1 5s. expenses.

The following journals have been received:—The 'British Medical Journal,' Dec. 26; the 'Medical Times and Gazette,' Dec. 26; the 'Lancet,' Dec. 26; the 'London Medical Record,' Dec. 26; 'Medical Press and Circular,' Dec. 26; 'Nature,' Dec. 26; 'Chemical News,' Dec. 26; 'Gardeners' Chronicle,' Dec. 26; the 'Grocer,' Dec. 26; 'Journal of the Society of Arts,' Dec. 26; 'Grocery News,' Dec. 31; 'Produce Markets Review,' Dec. 26; 'Practical Magazine,' for December; 'Educational Times,' for December; 'British Journal of Dental Science,' for December; 'Journal of Applied Science,' for January; 'Canadian Pharmaceutical Journal,' for December; 'Tennessee Pharmacal Journal,' for December; 'Moniteur Scientifique,' for December; 'Pharmaceutische Zeitung,' for Dec. 21 and 24; 'Sanitary Record,' Dec. 26; 'Journal de Pharmacie et de Chimie,' for December; 'Répertoire de Pharmacie,' for Dec. 20; 'The Garden,' for Dec. 26; 'American Journal of Pharmacy,' for December; 'The Pharmacist,' for December; 'Tennessee Pharmacal Gazette,' for December.

Preservation of Infusions.

Sir,—As the subject of preserved and concentrated infusions is still on the *tapis*, having some years ago been in the habit of using infusions preserved, as described by some of your correspondents, by heating the bottles containing them in a water-bath and tying them over with skin; and having so treated some hundreds of bottles myself, I beg to offer my opinion. Some infusions would undergo such treatment without much deterioration; others, such as cascarilla, senna, and gentian, differ as much from the fresh as fresh beef from Australian preserved, and the longer they are kept the greater the change. This plan was at length abandoned, as it was argued, that, supposing our household beverage, tea, were treated in the same manner, it would not be as palateable as when freshly prepared.

The tampering with the Pharmacopœia processes in making these useful and inexpensive preparations by pharmacists has done much to discredit their use by the medical profession, and to our regret they are much less frequently ordered than formerly. Such vapid substitutes as concentrated infusions for the grateful fresh preparations may satisfy requirements in some cases, but in my opinion they ought not to be used by a pharmaceutical chemist.

Wm. Martindale.

10, *New Cavendish Street,*
Dec. 29, 1874.

Spirit. Vini Rectif.

Sir,—It has been pointed out by a friend that absolute alcohol is not 100° but 75·25° over proof. In that case the calculation necessary would be still more complex and would be an additional argument for the simplicity of the American system. It will have been observed, I hope, that I purposely expressed, in the most general manner, the mode on which the calculation for over proof and under proof is based—having, indeed, originally written: let $x = $P.S. $a = $O.P.: $b = $U.P. assigning any given numerical value to a and b, the calculation to be worked accordingly. I am glad, however, to be able to add the above more accurate detail, and I am grateful for the kind intention which prompted the information. The same correspondent calls attention to a paper bearing on the subject by Drinkwater. *Pharm. Journal*, 1847.

Joseph Ince.

T. M. J.—(1) We do not know of a firm who would be willing to do what you require, but would recommend you to advertise in a dental journal. (2) We are not at present acquainted with a work confined to the subject you mention, but will make inquiries.

G. F.—(1) We cannot undertake to recommend the wares of any particular manufacturer. (2) Neither is correct; see the Calendar of the Pharmaceutical Society.

T. Robinson asks for a formula for a Hair Dye, but has forgotten to specify the colour.

H. G.—Before publishing your letter, or any portion of it, we shall be glad to learn if you have adequate grounds for believing the statements made in it beyond the mere representation of a customer. We have had opportunity of learning that such representations are not always to be depended upon in such cases.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

Communications, Letters, etc., have been received from Herr Rennard, Mr. Mason, Mr. Green, Mr. Siebold, Mr. Bell, Mr. Baynes, Mr. Metcalfe, Spes.

ON SYRUP OF FERROUS PHOSPHATE PREPARED FROM METALLIC IRON.

BY H. WILLIAMS JONES.

The British Pharmacopœia directs syrup of phosphate of iron to be made from precipitated phosphate, and, so far as I am aware, all published formulæ for the syrup direct precipitated ferrous phosphate to be used. Since phosphate of iron precipitated from mixed solutions of sulphate of iron and phosphate of soda is extremely difficult to wash and very liable to oxidation, as all know who have manipulated it, it occurred to me to prepare the phosphate direct from metallic iron by means of phosphoric acid. By this means a syrup is obtained which keeps remarkably well, which is quite free from the usual impurities arising from imperfect washing of the phosphate, which contains the phosphate of iron in an unoxidized condition, and which requires less free acid to keep it in solution. Further, the personal attention required in the preparation of the syrup by this means is much less than is required by any other process.

To prepare the syrup, cover the bottom of a jar or bottle, fitted with a cork, with coarse pure iron filings, and pour in phosphoric acid of about twice the strength of the diluted acid of the Pharmacopœia. Fit in the cork somewhat loosely, and let it stand for four or five hours. Action commences almost immediately, ferrous orthophosphate ($Fe_3P_2O_8$) is formed, and kept in solution by the free acid present. The hydrogen eliminated forms a hydrogen atmosphere in the jar, and prevents oxidation of the phosphate. At the end of the time named, the action will somewhat have ceased, and an acid solution of phosphate of iron will have been formed. To determine the proportion of iron in the solution, filter off 10 c.c., and titrate immediately with bichromate (B. P. solution) after the addition of hydrochloric acid and water. Each c.c. of bichromate = ·0358 gram $Fe_3P_2O_8$. If the operation has been properly conducted the iron will all be present in the ferrous state, so that the bichromate will give the total iron present. Having found out how much is contained in 10 c.c. we have only to multiply the number of grams found, by 5·4, when we have the number of grains of phosphate present in each fluid drachm of the liquor. Filter the remaining liquor, which, when poured off the iron, runs through paper quickly, and add sufficient syrup so that each fluid drachm shall contain 1 grain of phosphate of iron. If an acid of the strength named be left on the iron for five hours, more strong acid must be added to the syrup till it acquires a decidedly acid taste, when it will keep well. If it be considered a matter of importance that a definite amount of free acid should be present, note the sp. gr. of the original acid and calculate the amount of phosphoric acid removed by the iron. With an acid of known sp. gr., and, therefore, of known percentage of phosphoric acid, the bichromate solution gives with little calculation (1) the amount of phosphoric acid removed by the iron, and (2) the amount of free acid in the solution. The required quantity of acid can then be added. The Pharmacopœia syrup is much too acid, and 15 minims of acid. phosph. dil. in the drachm will be found quite enough, and the syrup will keep well with 12 minims. If the process be well conducted no phosphate of iron will be lost by precipitation. A solution seven times the strength of the syrup can be readily formed, which when mixed off with syrup forms an elegant preparation.

NOTE ON THE OCCURRENCE OF LEAD IN LEMONADE.

BY CHARLES EKIN, F.C.S.

In the number of the *Pharmaceutical Journal* for the 26th ult., there is a report of a trial at Glasgow where a manufacturer was fined for selling lemonade containing lead, and Dr. Russell, the Medical Officer of Health, is stated to have said "that he believed the lead in the lemonade arose from the character of the apparatus;" the manufacturer, however, saying, "that he had made alterations to avoid this risk, and did not know till now that there was lead in his apparatus."

I have lately been consulted in a similar case, and here, too, the manufacturer had taken every care by the use of wooden generators and vessels, together with block tin pipes and connections, to prevent the possibility of contamination, and yet his lemonade was analysed, and condemned as containing lead. He was naturally at his wits' end to know where the lead could come from, and as I have reason to believe the recent convictions have had the effect of producing something like a panic amongst many other aërated water makers, some of whom are also pharmaceutists, it may not be out of place to point out, in the pages of the *Pharmaceutical Journal*, an hitherto, so far as I know, unsuspected source of lead.

In the case I refer to, after having satisfied myself that the water used was free from lead, that there was no lead in the machinery, and that the lemonade syrup was neither made nor stored in glazed earthenware pans, the glaze of which might have contributed the adulterating metal, I examined the citric acid itself, and got such abundant evidence of lead that there could be no question in this case, at all events, what was the source of contamination.

The citric acid was purchased, I am informed, from a respectable drysalter, and I am unable to say at present how far it was an exceptional sample. That lead may, however, be frequently present in samples of commercial citric acid is rendered likely from the method of its manufacture, as detailed in Ure's Dictionary of Arts, Manufactures, and Mines, and also in Pereira's Materia Medica. It appears that the citrate of lime, formed by neutralizing lemon juice with chalk, is decomposed by diluted sulphuric acid, and the filtrate then concentrated by boiling down in *leaden* vessels. The crystals are afterwards purified by re-solution and re-crystallization; but as each re-solution and concentration is conducted in the same leaden boilers, and as triplumbic citrate is soluble, and the dibasic salt very soluble in a hot solution of citric acid, one can quite understand that in practice and commercially on the large scale complete purity cannot be obtained. Be that as it may, I purpose, when I have leisure, examining other samples, and in the meantime have thought that the recording of this special case might be of use at the present juncture.

CHEMISTRY OF THE TAR ANTISEPTICS.*

BY W. E. BICKERDIKE, F.C.S.

The subject which I propose to bring before you this evening is rather imperfectly described in the title of my paper. The tar antiseptics possess a very high degree, perhaps their highest degree, of interest and importance, in respect to those properties which render them so serviceable in a sanitary point, not only for the general puposes of disinfection for which they are extensively employed, but

* Read before the Liverpool Chemists' Association, December 17, 1874.

also for their application in the antiseptic method of treating surgical cases, which may be said to owe its origin to the employment of these bodies. An account of the tar antiseptics would be very imperfect if these characteristics were not included, and I propose briefly to refer to them, although they scarcely belong to the chemistry of the subject.

The tar antiseptics, I need hardly say, are derived from tar, and they form by no means the least interesting or useful group of compounds furnished by that prolific material. Gas tar, as is known, is a highly complex mixture; it consists of a great number of liquid and solid bodies, some of which have been very imperfectly studied.

It is probable that several of the constituents of tar possess more or less the characters of antiseptics, but this property is especially characteristic of the alcohols phenol and the isomeric cresols, commonly known as carbolic and cresylic acids. Possibly higher homologues of these compounds may exist, having similar properties; at the present time, however, these two bodies (which are really alcohols, and not acids) are by far the most important antiseptics contained in tar, and there can be no doubt that the ancient reputation of tar as an antiseptic was very largely owing to the presence therein of these so-called acids. By the term tar antiseptics, then, I refer especially to carbolic and cresylic acids, or, more correctly, phenol and cresol, these being the only bodies which are separated from coal tar, on the commercial scale, with a view to their employment as antiseptics.

In tracing the history of these products it is necessary to refer briefly to the treatment of tar by which its constituents are separated from one another. The first process consists of simple distillation by which the volatile portion is removed from the non-volatile. In this process, of course, the bodies with lowest boiling points first pass off, and as the temperature rises the higher products are driven over; when the volume is reduced to about one half, the tar has lost all its volatile constituents, and the residue is incapable of yielding further products, except by destructive distillation.

In the annexed diagram a list is given of the constituents of coal tar, together with the boiling point of each compound. The list will no doubt become greatly extended by further research.

CONSTITUENTS OF GAS TAR.

NAME.	Boiling point (Centigrade).
Hydrosulphuric Acid	
Ammonia	
Benzene	81
Water	100
Toluene	111
Pyridine	115
Pyrrol	133
Picoline	135
Xylene	139
Cumene	148
Lutidine	154
Collidine	170
Cymene	171
Anilin	182
Phenol	184
Parvoline	188
Paracresol	200
Naphthalene	212
Rubidine	230
Leucoline	235
Viridine	251
Cryptidine	256
Anthracene	350
Pyrene	
Chrysene	
Pitch	

On the first distillation of the tar, these products are, as you might expect, very much mixed together; in fact, we may compare the result to a spectrum in which the colours overlap one another, and in this second diagram, I have represented both the order in which the results present themselves, and approximatively the degree in which they are intermingled.

Light Oil.

Naphthalene.
Cumene, Phenol, Leuc line.
Pyrrol, Cymene, Rubidine, Cryptidine.
Toluene, Pyridine, Anilin, Naphthalene, Anthracene.
Benzene, Xylene, Cumene, Phenol, Cresol. Naphthalene. Chrysene.
Water, Toluene, Lutidine, Anilin, Leucoline, Pyrene.
Naphthalene, Cymene, Phenol, Viridine.
Collidine, Cresol.
Naphthalene.

The left-hand member (Benzene) represents the commencement of the distillation, and the right-hand member (Chrysene) the termination. By drawing a vertical line through the diagram at any point it will pass through the names of those substances which distil together. Naphthalene appears at almost every stage of the process, notwithstanding its boiling point is 212° C.

In the practical working of the operation this distillate is not all run into one receiving vessel, but it is collected in three or more separate portions. The first receiver is used so long as the liquid coming from the still is lighter than water. When the specific gravity reaches 1000 to 1010 the contents of the first receiver are set aside as "light oil;" the distillation is then continued in the second receptacle until the oil begins to contain Anthracene, when the vessel is again changed and the remainder of the distillate collected in the third receiver. These three portions are afterwards treated by special methods in order to separate any particular constituent that may be required. The first portion, or "light oil," contains the phenol and part of the cresol oil, and it is to this portion that we shall now confine our attention. In order to separate the phenol and cresol, the light oil is agitated for some hours with a solution of caustic soda, and after being allowed to stand for some time the soda solution is removed by decantation. This solution contains both the phenol and cresol dissolved, and on neutralizing the soda, these rise to the surface in the form of a dark oily liquid, consisting of phenol and cresol, together with some sulphur compounds, water, and a quantity of pitchy matter. The further separation of the phenol and cresol from this crude liquid is effected by repeated fractional distillation, assisted by crystallization of the phenol, from which the liquid cresol can be removed mechanically. When the process of purification has been carried as far as the present commercial methods will allow, we have the two bodies in the form of the samples before you. The solid phenol is of the quality commonly used for medical purposes: it is almost but not entirely free from cresol, but this is not important, as the latter is quite as effective an antiseptic as the former. The cresol contains a much larger proportion of phenol, amounting often to 15 or 20 per cent.; this mixture of cresol and phenol is commonly known in commerce as liquid carbolic acid; it is used almost solely for purposes of disinfection. Pure phenol is generally described in text books as crystallizing in long needles which fuse at 35° C. and boil at 186° C.; the crystals are also stated to be very deliquescent, and but sparingly soluble in water when melted. This description is not a very accurate one, being in fact a description of an impure body. Pure phenol fuses at 41° to 42° C., and boils at 184°; the crystals are not deliquescent. Water dissolves 5 per cent. of phenol at 16° C., but at 100° it will dissolve an unlimited quantity. On the other hand, the melted crystals will dissolve 20 to 25 per cent of water, and this prevents the crystallization of the phenol at ordinary temperatures. If, however, the mixture be exposed to a temperature of 0° C., a hydrate of phenol separates in the crystalline form. From the fact that phenol was separated from tar oil by means of an alkaline solution, and especially from its appearing to form a compound with potassic hydrate, it was supposed to possess an acid character; on further investigation, however, it was found to possess none of the characteristics of an acid, and it forms no definite salts with bases (Calvert, *Journal of the Chemical Society*, vol. viii., pp. 67 and 68). On the other hand, in its chemical relationships, it exhibits the character of an alcohol, and it may be regarded as the hydrate of the hypothetical radicle phenyl C_6H_5, just as ordinary alcohol is the hydrate of ethyl C_2H_5. Phenol is thus the alcohol of benzene, the first member of the aromatic series of hydrocarbons, and the analogy between ordinary alcohol and phenol is clearly shown if we write the formulæ of the different members of the series as derived from the radicle, of which the parent hydrocarbon may be considered the hydride. For instance, taking the radicles phenyl and ethyl respectively we have :—

	Phenyl Series.	Ethyl Series.
Hydride	$(C_6H_5)H$ or Benzene.	$(C_2H_5)H$ or Ethene.
Alcohol	$(C_6H_5)HO$ or Phenol.	$(C_2H_5)HO$ or Ethylic Alcohol.
Ether	$(C_6H_5)_2O$ or Phenylic Ether.	$(C_2H_5)O_2$ or Ethylic Ether.
Aldehyde	$(C_6H_5)COH$ or Phenylic Aldehyde.	$(C_2H_5)COH$ or Propylic Aldehyde.
Acid	$(C_6H_5)CO_2H$ or Benzoic Acid.	$(C_2H_5)CO_2H$ or Propionic Acid.
Ketone	$(C_6H_5)_2CO$ or Diphenyl Ketone.	$(C_2H_5)_2CO$ or Diethyl Ketone.

In the one case, the second member is the alcohol phenol, and in the other case, ordinary alcohol. There is therefore *primâ facie* evidence that phenol *may* be an alcohol merely from the fact that its composition as determined by analysis enables it to supply the place of the alcohol member in the phenyl series. But in the chemistry of carbon, where cases of isomerism and metamerism are so abundant, this fact is not sufficient, and it is necessary to seek for confirmatory evidence in the chemical behaviour of the compound. This evidence is furnished by several reactions in which phenol behaves in a manner closely analogous to ethylic alcohol under similar conditions. When, for instance, phenol is acted upon by potassium, hydrogen is given off and is replaced by the metal—

$$2\,C_6H_5OH + K_2 = 2\,C_6H_5OK + H_2.$$

In a similar manner when alcohol is acted upon by potassium the same interchange takes place—

$$2\,C_2H_5OH + K_2 = 2\,C_2H_5OK + H_2.$$

Again, when phenol is heated with sulphuric acid half the hydrogen of the acid is replaced by phenyl—

$$\left.\begin{matrix}H\\H\end{matrix}\right\}SO_4 + C_6H_5OH = \left.\begin{matrix}C_6H_5\\H\end{matrix}\right\}SO_4 + H_2O.$$

Sulphophenic acid being produced; from this the sulphophenates or sulphocarbolates are formed by replacing the remainder of the hydrogen by the metal whose salt is required. These changes are closely paralleled by the corresponding reactions of ethylic alcohol, which with sulphuric acid produces sulphethylic acid:—

$$\left.\begin{matrix}H\\H\end{matrix}\right\}SO_4 + C_2H_5OH = \left.\begin{matrix}C_2H_5\\H\end{matrix}\right\}SO_4 + H_2O.$$

In 1865 Calvert examined the white crystalline product which is formed when phenol is mixed with a strong solution of caustic potash, and which was supposed to be a salt of carbolic acid. It was found that the crystals consisted only of phenol, with a little adhering alkali. There can be no doubt therefore that phenol belongs to the alcohols, and absolutely pure phenol may be appropriately called "absolute phenol." Of this the sample before you is prepared in the form of minute granular crystals which fuse at 41° C. and boil at 184°. The crystals have a faint fragrant odour, and having no tendency to liquefy on exposure, they will probably be found a convenient pharmaceutical preparation. Phenol is produced by the dry distillation of several organic bodies besides coal, viz., salicylic acid, gum benzoin, resin of *Xanthorrhœa hastilis*, quinic acid, and chromate of pelosine. The action in the case of salicylic acid is especially interesting, as the latter may also be produced from phenol by the action of carbonic anhydride and sodium. At present salicylic acid is being manufactured from this source; its composition is the same as that of carbonic acid in which one atom of hydrogen is replaced by the radicle phenyl.

Carbonic acid.	Salicylic acid.
$\left.\begin{matrix}H\\H\end{matrix}\right\}CO_3$	$\left.\begin{matrix}C_6H_5\\H\end{matrix}\right\}CO_3$

A large number of derivatives have been furnished by phenol, some of which are of considerable commercial importance, although they were not applied to industrial uses to any great extent until nearly twenty years after the discovery of phenol; in fact, this body has a commercial history similar to that of oxalic acid, benzol, and many other organic compounds which, after their first discovery, were known for some years as chemical curiosities only, until at length they were found to possess qualities which make them useful to mankind, and which render their manufacture a profitable enterprise. It is little over twenty years since phenol was first manufactured on a large scale, and at the present time the production in this country amounts to several hundred tons annually. A large proportion of this is consumed in manufacturing two coloured derivatives of phenol which are employed as dyes. I allude to the picric and rosolic acids. When nitric acid is made to act upon phenol three different nitro-derivatives may be produced by varying the conditions under which the action takes place. In all cases the action consists in the replacement of part of the hydrogen of the phenol by the group nitryl (NO_3), and 1, 2, or 3 atoms of hydrogen may be so replaced, forming the mono-, di-, and tri-nitrophenic acids respectively, thus :—

Phenol.	Nitrophenic acids.		
C_6H_6O	$C_6H_5(NO_2)O$, (mono-)	$C_6H_4(NO_2)_2O$, (di-)	$C_6H_3(NO_2)_3O$ (tri-)

All these derivatives possess distinctly acid properties and form definite crystallizable salts, but only the last of them is of commercial importance. Trinitrophenic or picric acid is formed when nitric acid and phenol are allowed to react upon one another, and the mixture is afterwards boiled with concentrated nitric acid. Pure picric acid crystallizes in pale yellow needles, which dissolve in about eighty times their weight of cold water, forming an intensely yellow solution.

Like many organic compounds which have had 3 atoms of hydrogen replaced by 3 atoms of NO_2, such as gun cotton, or trinitronaphthalene, picric acid, and especially the picrates, are liable to undergo violent decomposition when heated, the picrates of the alkalies exploding with much violence. The most important application of picric acid is for dyeing silk or wool, to which it imparts a beautiful lemon-yellow shade; the acid merely requires to be dissolved in water with the addition of a little sulphuric acid, which is found to assist the process of dyeing. When a solution of picric acid is gently heated with cyanide of potassuim, isopurpurate of potassium is produced; from this the ammonium salt can be obtained which exactly resembles the dyeing material, murexid or purpurate of ammonium—

$$C_6H_3N_3O_7 + 3\,CNK + 3\,H_2O = C_8H_4KN_5O_6 + CO_2 + NH_3 + 2\,KHO.$$

The other coloured product derived from phenol is rosolic acid, known in commerce as aurine or coralline. This substance is produced when phenol is heated with an alkali, together with certain metallic oxides, and also when sulphophenic acid is heated with oxalic acid to a temperature of 120° C.; the last method is the one employed on the manufacturing scale. When the action is complete the excess of sulphophenic acid is washed out by repeatedly boiling with water, and the rosolic acid is finally melted in order to remove the water which it has retained; on cooling it assumes the condition of an amorphous mass with a beetle-green lustre, in which form it is know as aurine or yellow coralline of commerce. In this state rosolic acid contains a quantity of unchanged phenol; when freed from this it may be obtained in the crystalline form. Aurine is soluble in alkaline solutions and in alcohol; it is largely employed for dyeing silk and wool, to which it gives a bright orange colour often seen on sheepskin mats. When aurine is heated under pressure with ammonia solution to 150° C., a colouring matter is formed which produces a red shade instead of the orange shade imparted by aurine; this substance is called red coralline. A blue colouring matter is obtained from aurine by heating together aurine, anilin, and benzoic acid; this, at one time rather extensively used, is now supplanted by the anilin dyes.

We have now completed the list of colouring matters which are derived directly from phenol, and it will be admitted that the contributions of this body to the great magazine of tar-colours is by no means unimportant.

I now pass on to the consideration of some of the properties of cresylic acid or cresol. The remarks already made with reference to the constitution of phenol will equally apply to cresol, this body being an alcohol and not an acid. Three isomeric modifications of cresol are known which are distinguished as para,- meta-, and ortho-cresol, and these stand in the same relation to toluene as phenol does to benzene.

Toluene.	Cresol.
$(C_7H_7)H$	$(C_7H_7)OH$

Paracresol constitutes the greater portion of the crude cresol derived from coal-tar; it is very deliquescent and its presence in commercial phenol causes the latter to liquefy on exposure; its boiling point is about 200° C. Orthocresol is believed to exist in coal-tar, but it has also been obtained (as well as paracresol), by fusing potassium toluene-sulphate with potassium hydrate—

$$C_7H_7SO_3K + KOH = (C_7H_7)OH + K_2SO_3;$$

its boiling point is about 189° C.

Metacresol has not been obtained from coal-tar; it is formed by the resolution of thymol into cresol and propylene, by heating with phosphoric anhydride; its boiling point is 195° to 200°.

$$C_{10}H_{14}O = C_7H_8O + C_3H_6.$$

The derivatives of cresol have not been so perfectly studied as those of phenol, partly on account of the difficulty of obtaining the different isomers in a pure state in large quantities. None of them have yet been applied to any useful purpose in the arts or manufactures, but cresol itself is employed even to a greater extent than phenol for purposes of disinfection. The antiseptic qualities of cresol and phenol have been carefully studied during the last 10 or 15 years, and a large amount of experience has been gained by their practical employment as disinfectants. These alcohols possess some property by virtue of which they are able immediately to arrest those changes in organic bodies which owe their origin to the development of protoplasmic life. This is not effected by oxidation or other chemical change, as in the case of the permanganates, ozone, chlorine, etc., for there is reason to believe that the antiseptics themselves suffer no change. Both phenol and cresol will precipitate albumen and gelatine from their solutions, and it has been suggested that they may exert a similar power on the sarcode which forms the structure of the above-named organisms; whatever be the method by which the effect is produced, the fact itself is sufficiently established. Almost every species of decay to which organic matter is liable may be prevented by the presence of a minute quantity of the tar antiseptics, and from their volatile character they may be made to operate on the atmosphere as well as on liquid and solid bodies. This antiseptic quality was very soon recognised by medical authorities, and it was found that the usual septic condition of suppurating wounds might be entirely prevented by employing a dressing in which a small quantity of phenol or cresol was introduced; the subject was thoroughly investigated by Dr. Lister of Edinburgh, to whom we are chiefly indebted for the antiseptic method of treating wounds, and also for some of the very convenient forms in which the antiseptics are applied.

The question naturally arises, if these ntiseptics are so certain in their action upon the vital germs which accompany decay, may they not be useful agents for internal administration in those diseases in which the morbid state of the blood is supposed to be owing to the propagation therein of poisonous germs. Of course, it is impossible to administer either phenol or cresol in a pure state, and even a weak solution is found too irritating to the delicate mucous surfaces of the stomach, except in very small quantities, so that for some time the test could not be applied. Recently, however, it has been found that the salts of sulphocarbolic acid, which may be given in tolerably large doses, are decomposed in the system, the phenol being re-formed and set at liberty. By this method it is possible to administer phenol in such quantities as to produce cerebral symptoms, but I have not seen a sufficient number of reports as to its action to determine its success or otherwise. Numerous other applications of these antiseptics have been made, and are continually being made as their properties become more generally known. I will only allude to the preservation of gelatine size in hot weather, and of hides that are intended for tanning. Some years ago I had a thorough trial made of this method of preserving hides, in order to ascertain whether the antiseptic solution had any injurious effect on the after-process of tanning. The trial was made at the tan-yard of Mr. Beakbane, near Liverpool, and it was found that the hides were in no way injured by a 2 per cent. solution of the antiseptics, but after lying in a wet state during several weeks of warm weather they afterwards behaved in the tan-pit exactly like fresh hides. In conclusion, I beg to draw your attention to a few zoological specimens which were collected three years ago by my brother in India, and sent to England in a 2 per cent. solution of crude cresol. The state of preservation is complete.

MAGNESIUM SULPHITE.*

BY R. ROTHER.

On the large scale, magnesium sulphite is prepared by passing sulphurous oxide gas into water holding magnesium carbonate in suspension. The resulting product is the article found in the general market. This form is characterized by its peculiar snowy whiteness, granular appearance, and comparative lightness. By a different method, however, an article of magnesium sulphite can be produced which, in its physical character, is almost diametrically dissimilar to the one first mentioned. The course of double decomposition, as applied in the second instance, results in a form of this compound which is distinctly peculiar. The product in this case is invariably crystalline, but accordingly as the solution from which it separated was dilute or concentrated, the crystals will be transparent, or more or less white. From a moderately dilute solution the deposited crystals will be largest and best defined. Their general tendency, especially when the liquor is dilute, is to aggregate in clusters or crusts. The white crystals differ in no way from the transparent, or large, excepting in size. When the large crystals are crushed they apparently do not differ from the white. The transparent crystals are particularly noteworthy for

* From the *Tennessee Pharmacal Gazette.*

their brilliancy and glassy aspect, their extraordinary hardness and resistance to solution. Even when powdered, water attacks them but slowly, but an aqueous solution of sulphurous oxide dissolves them with rapidity.

The first process is not exactly convenient for preparing magnesium sulphite in the shop laboratory, however effective it may be in the hands of the manufacturing chemist. Besides, judging from the material which is employed, this process cannot possibly yield a perfectly pure salt.

The second process, or that of double decomposition, on the contrary, affords, with the aid of less complicated mechanical contrivances and the use of less expensive material, an absolutely pure product, appended to which are physical features significant of purity. Yet, in the course of the operation with the second method, it will be found that the crop of the expected sulphite does not accord with the theoretical amount—that is, the yield is only about two-thirds of what it should be.

By applying various modifications of this method the general result was not materially changed. Whether hot concentrated solutions of sodium sulphite and magnesium sulphate were mixed, or their dilute solutions united, and the magnesium sulphite successively gathered by consecutive evaporations, the amount of product did not appreciably vary. The important fact was incidentally ascertained that an excess of either of the two generating salts does not in the least affect the quantity of product.

Doubts were then entertained as to the composition of the thus generated sulphite, but when the salt was treated with iodine solution, the fact became apparent that it is the true sulphite of Rammelsberg, $Mg''SO_3.\ 6H_2O$, upon which the calculation had been based. The only remaining factor that could now bear upon the amount of product is the sodium sulphate resulting as a by-product. A quantity of magnesium sulphite was then added to a moderately strong solution of sodium sulphate, wherein it readily dissolved. The solution, on evaporation, failing to yield it up again, the fact became patent that about one-third of an equivalent of magnesium sulphite was permanently dissolved by one equivalent of sodium sulphate.

By letting a concentrated mother-liquor, from which all the available sulphite had crystallized, stand for some time, a portion of the sodium sulphate crystallized out, but the dense liquor poured from these crystals, on further evaporation, yielded an apparently amorphous residue.

The trial was not made whether magnesium chloride would give the whole of the magnesium as sulphite. However, in case this should be successful, then the addition of magnesium chloride to the mixed magnesium sulphite and sodium sulphate might probably evolve the magnesium sulphite by inducing a mutual disruption between itself and the sodium sulphate.

THE CHEMICAL NATURE OF DIGITALIN.*

BY C. KOSMANN.

There exists in the *Digitalis purpurea* an immediate principle which has been named successively digitalin, digitasolin, and digitaletin. This substance is soluble in water; it is very hygroscopic, and also readily altered by the action of water, acids and alkalies. When submitted to the action of dilute sulphuric or hydrochloric acid, it at first splits up into glucose and insoluble digitalin; but that being submitted to further action of the acid, breaks up again into glucose and digitaliretin, which has been also called paradigitaletin. This digitaliretin is by the prolonged action of the acid ultimately decomposed into dehydrated digitaliretin and four molecules of water.

* *Journal de Pharmacie et de Chimie* [4], vol. xx., p. 427.

Soluble digitalin is an immediate principle, so alterable by the action of energetic agents, such as acids, water, and heat, that the different substances which have been produced from the plant, under the names digitasolin, digitalin, digitaletin, paradigitaletin, and digitaliretin, are all derivatives of a single immediate principle in which reside in a high degree the medical properties of the plant. Digitalin exists in the plant in the soluble state; but, even there it is partially altered by aqueous, saline, or acid constituents, with which it comes into contact in the vegetable tissue, and is partly decomposed into glucose and insoluble digitalin. This is the reason why insoluble digitalin is always obtained from the plant, together with the soluble; the former, however, not being entirely insoluble in water, but much less soluble than the latter. Both these digitalins are glucosides; in the soluble digitalin the digitaliretin is combined with two molecules of sugar, in the insoluble with only one; the former upon losing one molecule of sugar is converted into the latter and becomes at the same time insoluble. Dissolved in dilute hydrochloric or sulphuric acid a molecule of the former is decomposed into one molecule of digitaliretin and two molecules of glucose; the latter into one molecule of digitaliretin and one of glucose. Both are very bitter and very energetic in the animal economy. The first is especially manufactured in Germany, the second in France.

The German process consists in treating the dried and powdered leaves with eight times their weight of 80° alcohol twice successively; the extremely bitter alcoholate is distilled to recover the greater part of the alcohol; the residue of the distillation is filtered, then treated with triplumbic acetate; the liquor filtered, treated with sulphuretted hydrogen to remove excess of lead, again filtered, and treated with a solution of tannin; the abundant precipitate is collected upon a filter, washed with water, and dissolved in alcohol; the alcoholic solution is treated with triplumbic acetate which precipitates the tannin as plumbic tannate; the solution is then filtered, excess of lead removed by sulphuretted hydrogen, again filtered, and evaporated slowly. The residue is treated first with ether, which dissolves the fatty and acrid matters, and then with alcohol to remove the digitalin, which is obtained by a slow evaporation of the solution. The soluble digitalin is separated from the insoluble by means of cold water, which dissolves the former and leaves the latter. The aqueous solution of soluble digitalin is treated with animal charcoal, or preferably, again with solution of tannin, the tannate of digitalin, redissolved in alcohol, is treated with triplumbic acetate, and after filtration, with sulphuretted hydrogen, again filtered, and then, being slowly evaporated, it yields soluble digitalin of a high degree of purity and extremely energetic. The yield thus obtained is:—

0·623 per cent. of soluble digitalin.
0·167 „ insoluble „

Altogether 0·790 per cent of product.

Soluble digitalin gave upon analysis—

		Required for formula $C_{54}H_{42}O_{27}$.*
C	55·26	55·69
H	7·89	7·26
O	36·85	37·05
	100·00	100·00

Soluble digitalin attracts water with avidity, and some which the author analysed in 1859 corresponded with the formula $C_{24}H_{42}O_{27} + 3\ HO$. On the other hand, insoluble digitalin, called also, in Germany, digitaletin, gives upon analysis,—

C	58·741
H	7·692
O	33·567

* C = 6; O = 8.

Its formula is—

$$\underbrace{C_{42}H_{33}O_{18}}_{\text{Insoluble digitalin.}} = \underbrace{C_{54}H_{45}O_{30}}_{\text{Hydrated soluble digitalin.}} - \underbrace{C_{12}H_{12}O_{12}}_{\text{Glucose.}}$$

Insoluble digitalin, treated with dilute sulphuric acid, gives up another molecule of glucose, and is converted into digitaliretin.

$$\underbrace{C_{42}H_{33}O_{18}}_{\text{Insoluble digitalin.}} + 4\,HO = \underbrace{C_{30}H_{25}O_{10}}_{\text{Digitaliretin.}} + C_{12}H_{12}O_{12}$$

Digitaliretin yielded upon analysis—

		Required for above formula.
C	63·225	63·50
H	8·414	8·77
O	28·361	27·73
	100·00	100·00

By the prolonged action of dilute sulphuric acid and heat, digitaliretin loses four molecules of water, and becomes dehydrated digitaliretin, which gives—

C	72·289
H	8·434
O	19·277
	100·00

This is the last stage of the decomposition of digitalin. Its formula is, $C_{30}H_{21}O_6 = C_{30}H_{25}O_{10} - 4\,HO$. It approaches closely the true resins in its large proportion of carbon. It melts at 60° C., has an acrid taste, is insoluble in water, and soluble in ammonia, ether, and alcohol; whilst digitaliretin ($C_{30}H_{25}O_{10}$) commences to melt at 169° C., is insoluble in water, ammonia, and caustic soda, slightly soluble in ether, soluble in warm alcohol, and has a slightly bitter taste. It occurs as a glistening crystalline powder, or in nacreous scales. The Germans also call it paradigitaletin.

If soluble digitalin be compared with salicin, it will be seen that there is a great resemblance between the two bodies: one molecule of soluble salicin by the loss of two molecules of glucose being converted into saligenin, much less soluble, and this by the loss of two molecules of water becomes insoluble saliretin. Moreover, salicin combines with bases, and the author has obtained a digitalinate of soda perfectly crystallized in a radiate form.

If the composition of the crystallized digitalin of MM. Homolle and Nativelle, be compared with that of digitalin, it will be seen that they have nearly the same centesimal composition.

	Homolle and Nativelle's crystallized digitalin.	C. Kosmann's digitaliretin.
C	62·08	63·225
H	8·23	8·414
O	29·69	28·361
	100·00	100·000

In fact, it is intermediate between insoluble digitalin and digitaliretin. For instance, if one molecule of insoluble digitalin and two molecules of digitaliretin be taken ($= C_{42}H_{33}O_{18} + 2C_{30}H_{25}O_{10}$), a mixture is obtained which has the centesimal composition—

C	61·261
H	8·308
O	30·431
	100·000

closely approaching that of the crystallized digitalin of MM. Homolle and Nativelle. If one molecule of the former and three of the latter be taken the mixture will contain in 100 parts—

C	61·682
H	8·411
O	29·907
	100·000

The author therefore considers it possible that the crystallized digitalin of MM. Homolle and Nativelle is a product which has already undergone partial alteration by the multiplicity of the manipulations. He further thinks it important that in medicine the soluble or insoluble digitalin, as obtained by the ordinary methods, should be adhered to, that product being very efficacious.

As to the digitalin of M. Nativelle, the author is induced to believe that it is far from being sufficiently pure for an elementary analysis. It gives for 100 parts—

C	54·72
H	9·22
O	36·06

These figures indicate no rational formula; divided by their equivalents they give $C_{18}H_{18}O_9$. If the centesimal figures were—

C	55·26
H	7·89
O	36·85

it would follow that this body was identical with the before-mentioned soluble digitalin, but the analysis of M. Nativelle gives considerably too much hydrogen.

In conclusion, the author considers himself justified in asserting that it is the soluble digitalin which is primarily elaborated by the plant, and which yields by decomposition the other above-named products.

PERCOLATION.

BY J. B. MOORE.

The following remarks upon Percolation are appended to the author's paper on Extract of Guarana, an abstract of which was given at p. 462:—

The powder, after being moistened for percolation should be passed through a sieve previously to packing, in order to break up any little lumps or aggregations that may be formed by the moisture. The sieve not only finely and uniformly divides the powder again and restores it to the *most perfect* condition for packing, but it also removes any portions that are imperfectly powdered or any accidental impurities.

Any one who has never tried this plan will be surprised at its advantages, and will sometimes be astonished at what the sieve will remove from powders that were apparently perfectly uniform and pure. Of course, the sieve employed for this purpose must not be too fine. For powders ranging from No. 40 to 80, about a No. 20 sieve will answer, and for coarser powders a coarser sieve in proportion.

Inexperienced operators are recommended in percolating powdered substances with which they are not familiar, or have not treated for some time, first to moisten only a small portion of the powder, pack it according to their best judgment, and pour upon it a small portion of the menstruum, just sufficient to see how it enters the powder. The unabsorbed portion should then be returned to the remainder of the menstruum and the moistened powder should be returned to the remainder of the powder, and thoroughly mixed with it before the addition of more menstruum. By this means a correct idea can generally be formed how the whole of the powder should be packed. It is important, however, not to take too much of the powder for these experimental trials, or the moisture absorbed by it may make the reserved portion of the powder, when mixed with it, too moist for correct packing. This simple expedient may often save the operator much vexation, and even *entire failure*, in important operations in making fluid extracts.

Many pharmacists are in the habit of using a stick or other instrument with which to stir the powder as the menstruum is added, as though contact with the substance would prove fatal. By this dainty method of manipulation, powders are often very irregularly and imperfectly moistened, and a much longer time is consumed in the operation than would otherwise be required, resulting, in hot weather, in a considerable loss of menstruum by evaporation. In this way, too, the powder is often left, full of lumps or masses, with some portions too moist, others too dry, and the whole in a bad condition for packing. The fastidious man who is afraid of soiling his hands in the legitimate operations of the laboratory or the dispensing counter, would be quite as likely to make a good blacksmith as a good pharmacist. This is rather a homely simile, but it is nevertheless a very expressive one.

It is one of the essential points in successful percolation to have the powder in just the right condition for packing, both as regards state of moisture as well as state of division. This can be most thoroughly and satisfactorily accomplished by rubbing the powder between the hands, as the moisture is added, and working it not unlike the practical housewife does her flour in the first part of the process in making bread. This thorough intermixing and rubbing uniformly and equally distributes the moisture, and also, in a measure, breaks up the lumps and little aggregations which often form in such powders when moistened. It is only by means of this kind of treatment, and the subsequent use of the sieve, as recommended above, that powders can be brought to that perfectly uniform condition so essential for correct packing for percolation.

When operating with substances which contain much colouring matter, such as the cinchonas, red saunders, etc., it will be well for the operator to wear a pair of india-rubber gloves, which will be found exceedingly useful to protect the hands in many operations of the laboratory.

In packing the powder in the percolator the author, when practicable, always uses the back of his fingers held firmly together; he can thus, by direct touch, know how much pressure he is using, and can regulate it with greater accuracy.

In packing, special attention should be given to the quantity of powder that is added to the percolator at a time, as well as to the amount of pressure used. In all ordinary operations the powder should be packed in small portions at a time, in strata of not more than from a quarter to a half inch in thickness. Many operators are in the habit of introducing the whole of the powder into the percolator at once, which is a great mistake, as then the mass receives the maximum of pressure at the very point at which it should receive the least, and that is at the top.

For several years the author has adopted the plan, especially when operating with a large quantity of any substance, to gradually diminish the pressure in packing as he nears the top, as it is the lower portions of the powder that are likely to escape thorough exhaustion. The upper portions have always the advantage of contact with the menstruum before its solvent power has become enfeebled, as it gradually does in its descent, so that when it reaches the extreme lower portions of the mass this power is almost entirely exhausted.

In cases where a preliminary maceration is considered necessary, and especially when the substance under treatment is of a tough, compact, and impenetrable nature, it is recommended that that portion of the menstruum with which the powder is moistened be previously heated, which can be easily done in a few minutes in a stone or tin vessel, or in a bottle tightly corked and placed in a water-bath. The maceration should also be conducted in a warm place.

The power of heat to expand vegetable tissue when moist, and to augment the power and energy of solvents, is well known; by its aid, when judiciously managed, the pharmacist may, in his manipulations, often greatly shorten tedious and lengthened processes.

It will generally be found necessary to moisten powders that are intended for preliminary maceration more than those intended for immediate percolation; otherwise they are apt, during the process, to become too dry for packing without afterwards being remoistened.

A NEW POULTICE.*

The time-honoured linseed-meal poultice seems to be about to be superseded by as cleanly and efficacious a substitute as the Rigollot papers which have so recently displaced its old companion-in-arms the mustard-poultice. M. Lefort, reporting to the Académie de Médecine on a new form of cataplasm invented by M. Lelièvre, speaks in the highest terms of its excellence. It is prepared by saturating two superimposed layers of wadding with a solution of *Fucus crispus*, and drying them in a stove after they have been submitted to strong pressure. In this way a sheet of the consistence of cardboard is produced, a portion of which is cut off when wanted, and soaked in hot water for fifteen or twenty minutes; this swelling it out and filling its tissue with a mucilaginous fluid. It has been tried in several of the hospitals to the great satisfaction of both patients and attendants. It can be prepared in large quantities beforehand, as when it has once been dried it will keep for a long time without undergoing any alteration.

M. Gosselin said that he had tried this cataplasm, and could speak as to its utility. When covered by an impermeable tissue, it does not dry up like other poultices, and especially it does not slide off from the part on which it is put, being sufficiently adherent to prevent its becoming displaced. M. Verneuil said that he had used it for several months in his wards, and had found it a most convenient application, for it can be cut and fashioned into any form or size desired. After being swollen out by soaking in warm water, it may remain in that state for twelve, eighteen, or even twenty hours; and after twelve hours it is as fresh as when first put on; so that it does not require renewal every five or six hours, like linseed-meal. It does not give rise to any bad smell, becoming at last only slightly acid. It neither softens nor crumbles; and as it does not soil either the parts or the linen, etc., it comes in contact with, it secures an amount of cleanliness that is of great importance. It is also economical, as it enables compresses and poultice-cloths which are so often badly washed and badly whitened, to be dispensed with. This latter point is also of importance as regards preventing the infection of wounds. M. Larrey believes that this emollient *fucus* is likewise to be of valuable service as a cataplasm in military service for hospitals and ambulances, by reason of its ready transport and facility of conservation. M. Demarquay, who has frequently employed these cataplasms, agrees with M. Larrey that they will prove very useful in ambulances, taking up so little room and keeping so well. M. Leroy de Méricourt believes that these cataplasms will be of great service in the navy. On board a ship it is usually impossible to wash poultice-cloths, while, as linseed-meal cannot be preserved, poultices have to be made of biscuit-dust, which produces very bad poultices. The inventor is of opinion that when his cataplasms are produced on a large scale they will be cheaper than linseeed-meal poultices.

THE JALAP PLANT.†

(*Exogonium purga.*)

Of all autumn-flowering hardy plants, there is, perhaps, none more beautiful than the Jalap (*Exogonium Purga*). Of its complete hardiness there can be little doubt. It has

lived at Bitton without any protection for four years, and each year it has flowered beautifully. We have also heard of its doing well at Drayton Beauchamp, Kew, and Fulham. We believe it has also lived out of doors, and flowered, in the Edinburgh Botanic Gardens. Mr. Ellacombe grows it in a sheltered corner, and gives it a tall wire cage to grow up, with a spreading top. It does not flower in the lower parts; but the entire top, and the pendent shoots, become a mass of most lovely blossoms. At Bitton, if not checked by late spring frosts, it comes into blossom early in September, and continues to flower till cut down by frost. Mr. Ellacombe states that, if he were to plant another, he should place it under a south wall near a peach or apricot tree, and let it wind its way through the branches. With a very little training, it would do no injury to the tree; and, in such a situation, it would probably flower earlier, and perfect its seeds. As regards its history, it gets its name of jalap from its native habitat, Xalapa, in Mexico. It is the true jalap of commerce; by which is not meant that it alone produces genuine jalap, but that it is *the* plant that gives the name to the medicine. The best jalap is made from the *Exogonium*; but good jalap may also be got from many other species of the *Convolvulaceæ*—even from our British species. "*Convolvulus arvensis, Soldanella, macrocarpus*, and probably many others, may likewise be used with nearly equal advantage," says Dr. Lindley. The habit of the plant is well given in the *Botanical Register*, v. 33; but the colour is not bright enough. It is also figured in the *Botanical Magazine*, v. 73. Can any one say if *Convolvulus* (*Batatas*) *Jalapa* is in cultivation, and if it has been found to be hardy? *E. purga* has, as will be seen, roundish tubers of variable size, those of mature growth being about as large as an orange, and of a dark colour. These, as we have said, are the true jalap tubers.
